[int or tuple of ints, optional] Output shape. If the given shape is, e.g., (m, n, k) , then $m * n * k$ samples are drawn. If size is None (default), a single value is returned if *a* is a scalar. Otherwise, `np.array(a).size` samples are drawn.

Returns**out**

[ndarray or scalar] Drawn samples from the parameterized Zipf distribution.

See also:**`scipy.stats.zipf`**

probability density function, distribution, or cumulative density function, etc.

`random.Generator.zipf`

which should be used for new code.

Notes

The probability mass function (PMF) for the Zipf distribution is

$$p(k) = \frac{k^{-a}}{\zeta(a)},$$

for integers $k \geq 1$, where ζ is the Riemann Zeta function.

It is named for the American linguist George Kingsley Zipf, who noted that the frequency of any word in a sample of a language is inversely proportional to its rank in the frequency table.

References

[1]

Examples

Draw samples from the distribution:

```
>>> a = 4.0
>>> n = 20000
>>> s = np.random.zipf(a, n)
```

Display the histogram of the samples, along with the expected histogram based on the probability density function:

```
>>> import matplotlib.pyplot as plt
>>> from scipy.special import zeta
```

`bincount` provides a fast histogram for small integers.

```
>>> count = np.bincount(s)
>>> k = np.arange(1, s.max() + 1)
```

```
>>> plt.bar(k, count[1:], alpha=0.5, label='sample count')
>>> plt.plot(k, n*(k**-a)/zeta(a), 'k.-', alpha=0.5,
...         label='expected count')
>>> plt.semilogy()
>>> plt.grid(alpha=0.4)
>>> plt.legend()
>>> plt.title(f'Zipf sample, a={a}, size={n}')
>>> plt.show()
```

Bit generators

The random values produced by *Generator* originate in a BitGenerator. The BitGenerators do not directly provide random numbers and only contains methods used for seeding, getting or setting the state, jumping or advancing the state, and for accessing low-level wrappers for consumption by code that can efficiently access the functions provided, e.g., *numba*.

Supported BitGenerators

The included BitGenerators are:

- PCG-64 - The default. A fast generator that can be advanced by an arbitrary amount. See the documentation for *advance*. PCG-64 has a period of 2^{128} . See the [PCG author's page](#) for more details about this class of PRNG.
- PCG-64 DXSM - An upgraded version of PCG-64 with better statistical properties in parallel contexts. See *Upgrading PCG64 with PCG64DXSM* for more information on these improvements.
- MT19937 - The standard Python BitGenerator. Adds a *MT19937.jumped* function that returns a new generator with state as-if 2^{128} draws have been made.
- Philox - A counter-based generator capable of being advanced an arbitrary number of steps or generating independent streams. See the [Random123](#) page for more details about this class of bit generators.
- SFC64 - A fast generator based on random invertible mappings. Usually the fastest generator of the four. See the [SFC author's page](#) for (a little) more detail.

<i>BitGenerator</i> ([seed])	Base Class for generic BitGenerators, which provide a stream of random bits based on different algorithms.
------------------------------	--

class `numpy.random.BitGenerator` (*seed=None*)

Base Class for generic BitGenerators, which provide a stream of random bits based on different algorithms. Must be overridden.

Parameters

seed

[{None, int, array_like[ints], SeedSequence}, optional] A seed to initialize the *BitGenerator*. If None, then fresh, unpredictable entropy will be pulled from the OS. If an int or array_like[ints] is passed, then it will be passed to *SeedSequence* to derive the initial *BitGenerator* state. One may also pass in a *SeedSequence* instance. All integer values must be non-negative.

Attributes

lock

[threading.Lock] Lock instance that is shared so that the same BitGenerator can be used in multiple Generators without corrupting the state. Code that generates values from a bit generator should hold the bit generator's lock.

Methods

<code>random_raw(self[, size])</code>	Return randoms as generated by the underlying Bit-Generator
<code>spawn(n_children)</code>	Create new independent child bit generators.

method

`random.BitGenerator.random_raw(self, size=None)`

Return randoms as generated by the underlying BitGenerator

Parameters

size

[int or tuple of ints, optional] Output shape. If the given shape is, e.g., (m, n, k) , then $m * n * k$ samples are drawn. Default is None, in which case a single value is returned.

output

[bool, optional] Output values. Used for performance testing since the generated values are not returned.

Returns

out

[uint or ndarray] Drawn samples.

Notes

This method directly exposes the raw underlying pseudo-random number generator. All values are returned as unsigned 64-bit values irrespective of the number of bits produced by the PRNG.

See the class docstring for the number of bits returned.

method

`random.BitGenerator.spawn(n_children)`

Create new independent child bit generators.

See *SeedSequence spawning* for additional notes on spawning children. Some bit generators also implement `jumped` as a different approach for creating independent streams.

New in version 1.25.0.

Parameters

n_children

[int]

Returns

child_bit_generators

[list of BitGenerators]

Raises

TypeError

When the underlying SeedSequence does not implement spawning.

See also:

random.Generator.spawn, *random.SeedSequence.spawn*

Equivalent method on the generator and seed sequence.

See also:

SeedSequence

Mersenne Twister (MT19937)

class `numpy.random.MT19937` (*seed=None*)

Container for the Mersenne Twister pseudo-random number generator.

Parameters

seed

[{None, int, array_like[ints], SeedSequence}, optional] A seed to initialize the *BitGenerator*. If None, then fresh, unpredictable entropy will be pulled from the OS. If an int or array_like[ints] is passed, then it will be passed to *SeedSequence* to derive the initial *BitGenerator* state. One may also pass in a *SeedSequence* instance.

Attributes

lock: `threading.Lock`

Lock instance that is shared so that the same bit generator can be used in multiple Generators without corrupting the state. Code that generates values from a bit generator should hold the bit generator's lock.

Notes

MT19937 provides a capsule containing function pointers that produce doubles, and unsigned 32 and 64-bit integers [1]. These are not directly consumable in Python and must be consumed by a *Generator* or similar object that supports low-level access.

The Python stdlib module “random” also contains a Mersenne Twister pseudo-random number generator.

State and Seeding

The *MT19937* state vector consists of a 624-element array of 32-bit unsigned integers plus a single integer value between 0 and 624 that indexes the current position within the main array.

The input seed is processed by *SeedSequence* to fill the whole state. The first element is reset such that only its most significant bit is set.

Parallel Features

The preferred way to use a BitGenerator in parallel applications is to use the *SeedSequence.spawn* method to obtain entropy values, and to use these to generate new BitGenerators:

```
>>> from numpy.random import Generator, MT19937, SeedSequence
>>> sg = SeedSequence(1234)
>>> rg = [Generator(MT19937(s)) for s in sg.spawn(10)]
```

Another method is to use *MT19937.jumped* which advances the state as-if 2^{128} random numbers have been generated ([1], [2]). This allows the original sequence to be split so that distinct segments can be used in each worker process. All generators should be chained to ensure that the segments come from the same sequence.

```
>>> from numpy.random import Generator, MT19937, SeedSequence
>>> sg = SeedSequence(1234)
>>> bit_generator = MT19937(sg)
>>> rg = []
>>> for _ in range(10):
...     rg.append(Generator(bit_generator))
...     # Chain the BitGenerators
...     bit_generator = bit_generator.jumped()
```

Compatibility Guarantee

MT19937 makes a guarantee that a fixed seed will always produce the same random integer stream.

References

[1], [2]

State

*state*Get or set the PRNG state

attribute

`random.MT19937.state`

Get or set the PRNG state

Returns

state

[dict] Dictionary containing the information required to describe the state of the PRNG

Parallel generation

jumped([jumps])Returns a new bit generator with the state jumped

method

`random.MT19937.jumped(jumps=1)`

Returns a new bit generator with the state jumped

The state of the returned bit generator is jumped as-if $2^{**}(128 * \text{jumps})$ random numbers have been generated.

Parameters

jumps

[integer, positive] Number of times to jump the state of the bit generator returned

Returns

bit_generator

[MT19937] New instance of generator jumped iter times

Notes

The jump step is computed using a modified version of Matsumoto's implementation of Horner's method. The step polynomial is precomputed to perform $2^{**}128$ steps. The jumped state has been verified to match the state produced using Matsumoto's original code.

Extending

<i>cfffi</i>	CFFI interface
<i>ctypes</i>	ctypes interface

attribute

`random.MT19937.cfffi`

CFFI interface

Returns

interface

[namedtuple] Named tuple containing CFFI wrapper

- `state_address` - Memory address of the state struct
- `state` - pointer to the state struct
- `next_uint64` - function pointer to produce 64 bit integers
- `next_uint32` - function pointer to produce 32 bit integers
- `next_double` - function pointer to produce doubles
- `bitgen` - pointer to the bit generator struct

attribute

`random.MT19937.ctypes`

ctypes interface

Returns

interface

[namedtuple] Named tuple containing ctypes wrapper

- `state_address` - Memory address of the state struct
- `state` - pointer to the state struct
- `next_uint64` - function pointer to produce 64 bit integers
- `next_uint32` - function pointer to produce 32 bit integers
- `next_double` - function pointer to produce doubles
- `bitgen` - pointer to the bit generator struct

Permuted congruential generator (64-bit, PCG64)

class `numpy.random.PCG64` (*seed=None*)

BitGenerator for the PCG-64 pseudo-random number generator.

Parameters

seed

[{None, int, array_like[ints], SeedSequence}, optional] A seed to initialize the *BitGenerator*. If None, then fresh, unpredictable entropy will be pulled from the OS. If an int or array_like[ints] is passed, then it will be passed to *SeedSequence* to derive the initial *BitGenerator* state. One may also pass in a *SeedSequence* instance.

Notes

PCG-64 is a 128-bit implementation of O'Neill's permutation congruential generator ([1], [2]). PCG-64 has a period of 2^{128} and supports advancing an arbitrary number of steps as well as 2^{127} streams. The specific member of the PCG family that we use is PCG XSL RR 128/64 as described in the paper ([2]).

PCG64 provides a capsule containing function pointers that produce doubles, and unsigned 32 and 64-bit integers. These are not directly consumable in Python and must be consumed by a *Generator* or similar object that supports low-level access.

Supports the method *advance* to advance the RNG an arbitrary number of steps. The state of the PCG-64 RNG is represented by 2 128-bit unsigned integers.

State and Seeding

The *PCG64* state vector consists of 2 unsigned 128-bit values, which are represented externally as Python ints. One is the state of the PRNG, which is advanced by a linear congruential generator (LCG). The second is a fixed odd increment used in the LCG.

The input seed is processed by *SeedSequence* to generate both values. The increment is not independently settable.

Parallel Features

The preferred way to use a BitGenerator in parallel applications is to use the *SeedSequence.spawn* method to obtain entropy values, and to use these to generate new BitGenerators:

```
>>> from numpy.random import Generator, PCG64, SeedSequence
>>> sg = SeedSequence(1234)
>>> rg = [Generator(PCG64(s)) for s in sg.spawn(10)]
```

Compatibility Guarantee

PCG64 makes a guarantee that a fixed seed will always produce the same random integer stream.

[1], [2]

State

<code>state</code>	Get or set the PRNG state
--------------------	---------------------------

attribute

`random.PCG64.state`

Get or set the PRNG state

Returns

state

[dict] Dictionary containing the information required to describe the state of the PRNG

Parallel generation

<code>advance(delta)</code>	Advance the underlying RNG as-if delta draws have occurred.
<code>jumped([jumps])</code>	Returns a new bit generator with the state jumped.

method

`random.PCG64.advance(delta)`

Advance the underlying RNG as-if delta draws have occurred.

Parameters

delta

[integer, positive] Number of draws to advance the RNG. Must be less than the size state variable in the underlying RNG.

Returns

self

[PCG64] RNG advanced delta steps

Notes

Advancing an RNG updates the underlying RNG state as-if a given number of calls to the underlying RNG have been made. In general there is not a one-to-one relationship between the number output random values from a particular distribution and the number of draws from the core RNG. This occurs for two reasons:

- The random values are simulated using a rejection-based method and so, on average, more than one value from the underlying RNG is required to generate a single draw.
- The number of bits required to generate a simulated value differs from the number of bits generated by the underlying RNG. For example, two 16-bit integer values can be simulated from a single draw of a 32-bit RNG.

Advancing the RNG state resets any pre-computed random numbers. This is required to ensure exact reproducibility.

method

`random.PCG64.jumped(jumps=1)`

Returns a new bit generator with the state jumped.

Jumps the state as-if `jumps * 210306068529402873165736369884012333109` random numbers have been generated.

Parameters

jumps

[integer, positive] Number of times to jump the state of the bit generator returned

Returns

bit_generator

[PCG64] New instance of generator jumped iter times

Notes

The step size is $\phi - 1$ when multiplied by 2^{128} where ϕ is the golden ratio.

Extending

<code>cfffi</code>	CFFI interface
<code>ctypes</code>	ctypes interface

attribute

`random.PCG64.cfffi`

CFFI interface

Returns

interface

[namedtuple] Named tuple containing CFFI wrapper

- `state_address` - Memory address of the state struct
- `state` - pointer to the state struct
- `next_uint64` - function pointer to produce 64 bit integers
- `next_uint32` - function pointer to produce 32 bit integers
- `next_double` - function pointer to produce doubles
- `bitgen` - pointer to the bit generator struct

attribute

`random.PCG64.ctypes`

ctypes interface

Returns

interface

[namedtuple] Named tuple containing ctypes wrapper

- `state_address` - Memory address of the state struct
- `state` - pointer to the state struct
- `next_uint64` - function pointer to produce 64 bit integers
- `next_uint32` - function pointer to produce 32 bit integers
- `next_double` - function pointer to produce doubles
- `bitgen` - pointer to the bit generator struct

Permuted congruential generator (64-bit, PCG64 DXSM)

class `numpy.random.PCG64DXSM` (*seed=None*)

BitGenerator for the PCG-64 DXSM pseudo-random number generator.

Parameters**seed**

[[None, int, array_like[ints], SeedSequence], optional] A seed to initialize the *BitGenerator*. If None, then fresh, unpredictable entropy will be pulled from the OS. If an int or array_like[ints] is passed, then it will be passed to *SeedSequence* to derive the initial *BitGenerator* state. One may also pass in a *SeedSequence* instance.

Notes

PCG-64 DXSM is a 128-bit implementation of O’Neill’s permutation congruential generator ([1], [2]). PCG-64 DXSM has a period of 2^{128} and supports advancing an arbitrary number of steps as well as 2^{127} streams. The specific member of the PCG family that we use is PCG CM DXSM 128/64. It differs from *PCG64* in that it uses the stronger DXSM output function, a 64-bit “cheap multiplier” in the LCG, and outputs from the state before advancing it rather than advance-then-output.

PCG64DXSM provides a capsule containing function pointers that produce doubles, and unsigned 32 and 64-bit integers. These are not directly consumable in Python and must be consumed by a *Generator* or similar object that supports low-level access.

Supports the method *advance* to advance the RNG an arbitrary number of steps. The state of the PCG-64 DXSM RNG is represented by 2 128-bit unsigned integers.

State and Seeding

The *PCG64DXSM* state vector consists of 2 unsigned 128-bit values, which are represented externally as Python ints. One is the state of the PRNG, which is advanced by a linear congruential generator (LCG). The second is a fixed odd increment used in the LCG.

The input seed is processed by *SeedSequence* to generate both values. The increment is not independently settable.

Parallel Features

The preferred way to use a BitGenerator in parallel applications is to use the *SeedSequence.spawn* method to obtain entropy values, and to use these to generate new BitGenerators:

```
>>> from numpy.random import Generator, PCG64DXSM, SeedSequence
>>> sg = SeedSequence(1234)
>>> rg = [Generator(PCG64DXSM(s)) for s in sg.spawn(10)]
```

Compatibility Guarantee

PCG64DXSM makes a guarantee that a fixed seed will always produce the same random integer stream.

<i>advance</i> (delta)	Advance the underlying RNG as-if delta draws have occurred.
<i>jumped</i> ([jumps])	Returns a new bit generator with the state jumped.

method

`random.PCG64DXSM.advance(delta)`

Advance the underlying RNG as-if delta draws have occurred.

Parameters

delta

[integer, positive] Number of draws to advance the RNG. Must be less than the size state variable in the underlying RNG.

Returns

self

[PCG64] RNG advanced delta steps

Notes

Advancing an RNG updates the underlying RNG state as-if a given number of calls to the underlying RNG have been made. In general there is not a one-to-one relationship between the number output random values from a particular distribution and the number of draws from the core RNG. This occurs for two reasons:

- The random values are simulated using a rejection-based method and so, on average, more than one value from the underlying RNG is required to generate a single draw.
- The number of bits required to generate a simulated value differs from the number of bits generated by the underlying RNG. For example, two 16-bit integer values can be simulated from a single draw of a 32-bit RNG.

Advancing the RNG state resets any pre-computed random numbers. This is required to ensure exact reproducibility.

method

`random.PCG64DXSM.jumped(jumps=1)`

Returns a new bit generator with the state jumped.

Jumps the state as-if `jumps * 210306068529402873165736369884012333109` random numbers have been generated.

Parameters

jumps

[integer, positive] Number of times to jump the state of the bit generator returned

Returns

bit_generator

[PCG64DXSM] New instance of generator jumped iter times

Notes

The step size is $\phi - 1$ when multiplied by 2^{128} where ϕ is the golden ratio.

- `next_uint32` - function pointer to produce 32 bit integers
- `next_double` - function pointer to produce doubles
- `bitgen` - pointer to the bit generator struct

Philox counter-based RNG

class `numpy.random.Philox` (*seed=None, counter=None, key=None*)

Container for the Philox (4x64) pseudo-random number generator.

Parameters

seed

[{None, int, array_like[ints], SeedSequence}, optional] A seed to initialize the *BitGenerator*. If None, then fresh, unpredictable entropy will be pulled from the OS. If an int or array_like[ints] is passed, then it will be passed to *SeedSequence* to derive the initial *BitGenerator* state. One may also pass in a *SeedSequence* instance.

counter

[{None, int, array_like}, optional] Counter to use in the Philox state. Can be either a Python int (long in 2.x) in [0, 2**256) or a 4-element uint64 array. If not provided, the RNG is initialized at 0.

key

[{None, int, array_like}, optional] Key to use in the Philox state. Unlike *seed*, the value in *key* is directly set. Can be either a Python int in [0, 2**128) or a 2-element uint64 array. *key* and *seed* cannot both be used.

Attributes

lock: `threading.Lock`

Lock instance that is shared so that the same bit generator can be used in multiple Generators without corrupting the state. Code that generates values from a bit generator should hold the bit generator's lock.

Notes

Philox is a 64-bit PRNG that uses a counter-based design based on weaker (and faster) versions of cryptographic functions [1]. Instances using different values of the key produce independent sequences. Philox has a period of $2^{256} - 1$ and supports arbitrary advancing and jumping the sequence in increments of 2^{128} . These features allow multiple non-overlapping sequences to be generated.

Philox provides a capsule containing function pointers that produce doubles, and unsigned 32 and 64-bit integers. These are not directly consumable in Python and must be consumed by a *Generator* or similar object that supports low-level access.

State and Seeding

The *Philox* state vector consists of a 256-bit value encoded as a 4-element uint64 array and a 128-bit value encoded as a 2-element uint64 array. The former is a counter which is incremented by 1 for every 4 64-bit randoms produced. The second is a key which determined the sequence produced. Using different keys produces independent sequences.

The input seed is processed by *SeedSequence* to generate the key. The counter is set to 0.

Alternately, one can omit the *seed* parameter and set the *key* and *counter* directly.

Parallel Features

The preferred way to use a BitGenerator in parallel applications is to use the *SeedSequence.spawn* method to obtain entropy values, and to use these to generate new BitGenerators:

```
>>> from numpy.random import Generator, Philox, SeedSequence
>>> sg = SeedSequence(1234)
>>> rg = [Generator(Philox(s)) for s in sg.spawn(10)]
```

Philox can be used in parallel applications by calling the *jumped* method to advance the state as-if 2^{128} random numbers have been generated. Alternatively, *advance* can be used to advance the counter for any positive step in $[0, 2^{256})$. When using *jumped*, all generators should be chained to ensure that the segments come from the same sequence.

```
>>> from numpy.random import Generator, Philox
>>> bit_generator = Philox(1234)
>>> rg = []
>>> for _ in range(10):
...     rg.append(Generator(bit_generator))
...     bit_generator = bit_generator.jumped()
```

Alternatively, *Philox* can be used in parallel applications by using a sequence of distinct keys where each instance uses different key.

```
>>> key = 2**96 + 2**33 + 2**17 + 2**9
>>> rg = [Generator(Philox(key=key+i)) for i in range(10)]
```

Compatibility Guarantee

Philox makes a guarantee that a fixed *seed* will always produce the same random integer stream.

References

[1]

Examples

```
>>> from numpy.random import Generator, Philox
>>> rg = Generator(Philox(1234))
>>> rg.standard_normal()
0.123 # random
```

State

<code>state</code>	Get or set the PRNG state
--------------------	---------------------------

attribute

`random.Philox.state`

Get or set the PRNG state

Returns

state

[dict] Dictionary containing the information required to describe the state of the PRNG

Parallel generation

<code>advance(delta)</code>	Advance the underlying RNG as-if delta draws have occurred.
<code>jumped([jumps])</code>	Returns a new bit generator with the state jumped

method

`random.Philox.advance(delta)`

Advance the underlying RNG as-if delta draws have occurred.

Parameters

delta

[integer, positive] Number of draws to advance the RNG. Must be less than the size state variable in the underlying RNG.

Returns

self

[Philox] RNG advanced delta steps

Notes

Advancing an RNG updates the underlying RNG state as-if a given number of calls to the underlying RNG have been made. In general there is not a one-to-one relationship between the number output random values from a particular distribution and the number of draws from the core RNG. This occurs for two reasons:

- The random values are simulated using a rejection-based method and so, on average, more than one value from the underlying RNG is required to generate a single draw.
- The number of bits required to generate a simulated value differs from the number of bits generated by the underlying RNG. For example, two 16-bit integer values can be simulated from a single draw of a 32-bit RNG.

Advancing the RNG state resets any pre-computed random numbers. This is required to ensure exact reproducibility.

method

```
random.Philox.jumped(jumps=1)
```

Returns a new bit generator with the state jumped

The state of the returned bit generator is jumped as-if $(2^{128}) * \text{jumps}$ random numbers have been generated.

Parameters

jumps
[integer, positive] Number of times to jump the state of the bit generator returned

Returns

bit_generator
[Philox] New instance of generator jumped iter times

Extending

<i>cfffi</i>	CFFI interface
<i>ctypes</i>	ctypes interface

attribute

```
random.Philox.cfffi
```

CFFI interface

Returns

interface
[namedtuple] Named tuple containing CFFI wrapper

- state_address - Memory address of the state struct
- state - pointer to the state struct
- next_uint64 - function pointer to produce 64 bit integers
- next_uint32 - function pointer to produce 32 bit integers
- next_double - function pointer to produce doubles
- bitgen - pointer to the bit generator struct

attribute

`random.Philox.ctypes`

ctypes interface

Returns

interface

[namedtuple] Named tuple containing ctypes wrapper

- `state_address` - Memory address of the state struct
- `state` - pointer to the state struct
- `next_uint64` - function pointer to produce 64 bit integers
- `next_uint32` - function pointer to produce 32 bit integers
- `next_double` - function pointer to produce doubles
- `bitgen` - pointer to the bit generator struct

SFC64 Small Fast Chaotic PRNG

class `numpy.random.SFC64` (*seed=None*)

BitGenerator for Chris Doty-Humphrey's Small Fast Chaotic PRNG.

Parameters

seed

[{None, int, array_like[ints], SeedSequence}, optional] A seed to initialize the *BitGenerator*. If None, then fresh, unpredictable entropy will be pulled from the OS. If an `int` or `array_like[ints]` is passed, then it will be passed to *SeedSequence* to derive the initial *BitGenerator* state. One may also pass in a *SeedSequence* instance.

Notes

SFC64 is a 256-bit implementation of Chris Doty-Humphrey's Small Fast Chaotic PRNG ([1]). *SFC64* has a few different cycles that one might be on, depending on the seed; the expected period will be about 2^{255} ([2]). *SFC64* incorporates a 64-bit counter which means that the absolute minimum cycle length is 2^{64} and that distinct seeds will not run into each other for at least 2^{64} iterations.

SFC64 provides a capsule containing function pointers that produce doubles, and unsigned 32 and 64- bit integers. These are not directly consumable in Python and must be consumed by a *Generator* or similar object that supports low-level access.

State and Seeding

The *SFC64* state vector consists of 4 unsigned 64-bit values. The last is a 64-bit counter that increments by 1 each iteration.

The input seed is processed by *SeedSequence* to generate the first 3 values, then the *SFC64* algorithm is iterated a small number of times to mix.

Compatibility Guarantee

SFC64 makes a guarantee that a fixed seed will always produce the same random integer stream.

<i>ctypes</i>	ctypes interface

attribute

`random.SFC64.cffi`
CFFI interface

Returns

interface
[namedtuple] Named tuple containing CFFI wrapper

- `state_address` - Memory address of the state struct
- `state` - pointer to the state struct
- `next_uint64` - function pointer to produce 64 bit integers
- `next_uint32` - function pointer to produce 32 bit integers
- `next_double` - function pointer to produce doubles
- `bitgen` - pointer to the bit generator struct

attribute

`random.SFC64.ctypes`
ctypes interface

Returns

interface
[namedtuple] Named tuple containing ctypes wrapper

- `state_address` - Memory address of the state struct

- `state` - pointer to the state struct
- `next_uint64` - function pointer to produce 64 bit integers
- `next_uint32` - function pointer to produce 32 bit integers
- `next_double` - function pointer to produce doubles
- `bitgen` - pointer to the bit generator struct

Seeding and entropy

A BitGenerator provides a stream of random values. In order to generate reproducible streams, BitGenerators support setting their initial state via a seed. All of the provided BitGenerators will take an arbitrary-sized non-negative integer, or a list of such integers, as a seed. BitGenerators need to take those inputs and process them into a high-quality internal state for the BitGenerator. All of the BitGenerators in numpy delegate that task to *SeedSequence*, which uses hashing techniques to ensure that even low-quality seeds generate high-quality initial states.

```
from numpy.random import PCG64

bg = PCG64(12345678903141592653589793)
```

SeedSequence is designed to be convenient for implementing best practices. We recommend that a stochastic program defaults to using entropy from the OS so that each run is different. The program should print out or log that entropy. In order to reproduce a past value, the program should allow the user to provide that value through some mechanism, a command-line argument is common, so that the user can then re-enter that entropy to reproduce the result. *SeedSequence* can take care of everything except for communicating with the user, which is up to you.

```
from numpy.random import PCG64, SeedSequence

# Get the user's seed somehow, maybe through `argparse`.
# If the user did not provide a seed, it should return `None`.
seed = get_user_seed()
ss = SeedSequence(seed)
print(f'seed = {ss.entropy}')
bg = PCG64(ss)
```

We default to using a 128-bit integer using entropy gathered from the OS. This is a good amount of entropy to initialize all of the generators that we have in numpy. We do not recommend using small seeds below 32 bits for general use. Using just a small set of seeds to instantiate larger state spaces means that there are some initial states that are impossible to reach. This creates some biases if everyone uses such values.

There will not be anything *wrong* with the results, per se; even a seed of 0 is perfectly fine thanks to the processing that *SeedSequence* does. If you just need *some* fixed value for unit tests or debugging, feel free to use whatever seed you like. But if you want to make inferences from the results or publish them, drawing from a larger set of seeds is good practice.

If you need to generate a good seed “offline”, then `SeedSequence().entropy` or using `secrets.randbits(128)` from the standard library are both convenient ways.

If you need to run several stochastic simulations in parallel, best practice is to construct a random generator instance for each simulation. To make sure that the random streams have distinct initial states, you can use the *spawn* method of *SeedSequence*. For instance, here we construct a list of 12 instances:

```
from numpy.random import PCG64, SeedSequence

# High quality initial entropy
```

(continues on next page)

(continued from previous page)

```
entropy = 0x87351080e25cb0fad77a44a3be03b491
base_seq = SeedSequence(entropy)
child_seqs = base_seq.spawn(12)    # a list of 12 SeedSequences
generators = [PCG64(seq) for seq in child_seqs]
```

If you already have an initial random generator instance, you can shorten the above by using the `spawn` method:

```
from numpy.random import PCG64, SeedSequence
# High quality initial entropy
entropy = 0x87351080e25cb0fad77a44a3be03b491
base_bitgen = PCG64(entropy)
generators = base_bitgen.spawn(12)
```

An alternative way is to use the fact that a `SeedSequence` can be initialized by a tuple of elements. Here we use a base entropy value and an integer `worker_id`

```
from numpy.random import PCG64, SeedSequence

# High quality initial entropy
entropy = 0x87351080e25cb0fad77a44a3be03b491
sequences = [SeedSequence((entropy, worker_id)) for worker_id in range(12)]
generators = [PCG64(seq) for seq in sequences]
```

Note that the sequences produced by the latter method will be distinct from those constructed via `spawn`.

`SeedSequence([entropy, spawn_key, ...])`

`SeedSequence` mixes sources of entropy in a reproducible way to set the initial state for independent and very probably non-overlapping BitGenerators.

class `numpy.random.SeedSequence` (*entropy=None*, *, *spawn_key=()*, *pool_size=4*, *n_children_spawned=0*)

`SeedSequence` mixes sources of entropy in a reproducible way to set the initial state for independent and very probably non-overlapping BitGenerators.

Once the `SeedSequence` is instantiated, you can call the `generate_state` method to get an appropriately sized seed. Calling `spawn(n)` will create `n` `SeedSequences` that can be used to seed independent BitGenerators, i.e. for different threads.

Parameters

entropy

[{None, int, sequence[int]}, optional] The entropy for creating a `SeedSequence`. All integer values must be non-negative.

spawn_key

[{(), sequence[int]}, optional] An additional source of entropy based on the position of this `SeedSequence` in the tree of such objects created with the `SeedSequence.spawn` method. Typically, only `SeedSequence.spawn` will set this, and users will not.

pool_size

[{int}, optional] Size of the pooled entropy to store. Default is 4 to give a 128-bit entropy pool. 8 (for 256 bits) is another reasonable choice if working with larger PRNGs, but there is very little to be gained by selecting another value.

n_children_spawned

[{int}, optional] The number of children already spawned. Only pass this if reconstructing a `SeedSequence` from a serialized form.

Attributes

entropy
n_children_spawned
pool
pool_size
spawn_key
state

Methods

<code>generate_state(n_words[, dtype])</code>	Return the requested number of words for PRNG seeding.
<code>spawn(n_children)</code>	Spawn a number of child <i>SeedSequence</i> s by extending the <code>spawn_key</code> .

method

`random.SeedSequence.generate_state(n_words, dtype=np.uint32)`

Return the requested number of words for PRNG seeding.

A BitGenerator should call this method in its constructor with an appropriate *n_words* parameter to properly seed itself.

Parameters

n_words
[int]

dtype
[np.uint32 or np.uint64, optional] The size of each word. This should only be either *uint32* or *uint64*. Strings (*'uint32'*, *'uint64'*) are fine. Note that requesting *uint64* will draw twice as many bits as *uint32* for the same *n_words*. This is a convenience for *BitGenerators* that express their states as *uint64* arrays.

Returns

state
[uint32 or uint64 array, shape=(n_words,)]

method

`random.SeedSequence.spawn(n_children)`

Spawn a number of child *SeedSequence* s by extending the `spawn_key`.

See *SeedSequence spawning* for additional notes on spawning children.

Parameters

n_children
[int]

Returns

seqs
[list of *SeedSequence* s]

See also:

`random.Generator.spawn`, `random.BitGenerator.spawn`

Equivalent method on the generator and bit generator.

Notes

Best practice for achieving reproducible bit streams is to use the default `None` for the initial entropy, and then use `SeedSequence.entropy` to log/pickle the entropy for reproducibility:

```
>>> sq1 = np.random.SeedSequence()
>>> sq1.entropy
243799254704924441050048792905230269161 # random
>>> sq2 = np.random.SeedSequence(sq1.entropy)
>>> np.all(sq1.generate_state(10) == sq2.generate_state(10))
True
```

Upgrading PCG64 with PCG64DXSM

Uses of the *PCG64 BitGenerator* in a massively-parallel context have been shown to have statistical weaknesses that were not apparent at the first release in numpy 1.17. Most users will never observe this weakness and are safe to continue to use *PCG64*. We have introduced a new *PCG64DXSM BitGenerator* that will eventually become the new default *BitGenerator* implementation used by *default_rng* in future releases. *PCG64DXSM* solves the statistical weakness while preserving the performance and the features of *PCG64*.

Does this affect me?

If you

1. only use a single *Generator* instance,
2. only use *RandomState* or the functions in *numpy.random*,
3. only use the *PCG64.jumped* method to generate parallel streams,
4. explicitly use a *BitGenerator* other than *PCG64*,

then this weakness does not affect you at all. Carry on.

If you use moderate numbers of parallel streams created with *default_rng* or *SeedSequence.spawn*, in the 1000s, then the chance of observing this weakness is negligibly small. You can continue to use *PCG64* comfortably.

If you use very large numbers of parallel streams, in the millions, and draw large amounts of numbers from each, then the chance of observing this weakness can become non-negligible, if still small. An example of such a use case would be a very large distributed reinforcement learning problem with millions of long Monte Carlo playouts each generating billions of random number draws. Such use cases should consider using *PCG64DXSM* explicitly or another modern *BitGenerator* like *SFC64* or *Philox*, but it is unlikely that any old results you may have calculated are invalid. In any case, the weakness is a kind of *Birthday Paradox* collision. That is, a single pair of parallel streams out of the millions, considered together, might fail a stringent set of statistical tests of randomness. The remaining millions of streams would all be perfectly fine, and the effect of the bad pair in the whole calculation is very likely to be swamped by the remaining streams in most applications.

Technical details

Like many PRNG algorithms, `PCG64` is constructed from a transition function, which advances a 128-bit state, and an output function, that mixes the 128-bit state into a 64-bit integer to be output. One of the guiding design principles of the PCG family of PRNGs is to balance the computational cost (and pseudorandomness strength) between the transition function and the output function. The transition function is a 128-bit linear congruential generator (LCG), which consists of multiplying the 128-bit state with a fixed multiplication constant and then adding a user-chosen increment, in 128-bit modular arithmetic. LCGs are well-analyzed PRNGs with known weaknesses, though 128-bit LCGs are large enough to pass stringent statistical tests on their own, with only the trivial output function. The output function of `PCG64` is intended to patch up some of those known weaknesses by doing “just enough” scrambling of the bits to assist in the statistical properties without adding too much computational cost.

One of these known weaknesses is that advancing the state of the LCG by steps numbering a power of two (`bg.advance(2**N)`) will leave the lower N bits identical to the state that was just left. For a single stream drawn from sequentially, this is of little consequence. The remaining $128 - N$ bits provide plenty of pseudorandomness that will be mixed in for any practical N that can be observed in a single stream, which is why one does not need to worry about this if you only use a single stream in your application. Similarly, the `PCG64.jumped` method uses a carefully chosen number of steps to avoid creating these collisions. However, once you start creating “randomly-initialized” parallel streams, either using OS entropy by calling `default_rng` repeatedly or using `SeedSequence.spawn`, then we need to consider how many lower bits need to “collide” in order to create a bad pair of streams, and then evaluate the probability of creating such a collision. Empirically, it has been determined that if one shares the lower 58 bits of state and shares an increment, then the pair of streams, when interleaved, will fail `PractRand` in a reasonable amount of time, after drawing a few gigabytes of data. Following the standard Birthday Paradox calculations for a collision of 58 bits, we can see that we can create 2^{29} , or about half a billion, streams which is when the probability of such a collision becomes high. Half a billion streams is quite high, and the amount of data each stream needs to draw before the statistical correlations become apparent to even the strict `PractRand` tests is in the gigabytes. But this is on the horizon for very large applications like distributed reinforcement learning. There are reasons to expect that even in these applications a collision probably will not have a practical effect in the total result, since the statistical problem is constrained to just the colliding pair.

Now, let us consider the case when the increment is not constrained to be the same. Our implementation of `PCG64` seeds both the state and the increment; that is, two calls to `default_rng` (almost certainly) have different states and increments. Upon our first release, we believed that having the seeded increment would provide a certain amount of extra protection, that one would have to be “close” in both the state space and increment space in order to observe correlations (`PractRand` failures) in a pair of streams. If that were true, then the “bottleneck” for collisions would be the 128-bit entropy pool size inside of `SeedSequence` (and 128-bit collisions are in the “preposterously unlikely” category). Unfortunately, this is not true.

One of the known properties of an LCG is that different increments create *distinct* streams, but with a known relationship. Each LCG has an orbit that traverses all 2^{128} different 128-bit states. Two LCGs with different increments are related in that one can “rotate” the orbit of the first LCG (advance it by a number of steps that we can compute from the two increments) such that then both LCGs will always then have the same state, up to an additive constant and maybe an inversion of the bits. If you then iterate both streams in lockstep, then the states will *always* remain related by that same additive constant (and the inversion, if present). Recall that `PCG64` is constructed from both a transition function (the LCG) and an output function. It was expected that the scrambling effect of the output function would have been strong enough to make the distinct streams practically independent (i.e. “passing the `PractRand` tests”) unless the two increments were pathologically related to each other (e.g. 1 and 3). The output function XSL-RR of the then-standard PCG algorithm that we implemented in `PCG64` turns out to be too weak to cover up for the 58-bit collision of the underlying LCG that we described above. For any given pair of increments, the size of the “colliding” space of states is the same, so for this weakness, the extra distinctness provided by the increments does not translate into extra protection from statistical correlations that `PractRand` can detect.

Fortunately, strengthening the output function is able to correct this weakness and *does* turn the extra distinctness provided by differing increments into additional protection from these low-bit collisions. To the [PCG author's credit](#), she had developed a stronger output function in response to related discussions during the long birth of the new `BitGenerator` system. We NumPy developers chose to be “conservative” and use the XSL-RR variant that had undergone a longer period of testing at that time. The DXSM output function adopts a “xorshift-multiply” construction used in strong integer

hashes that has much better avalanche properties than the XSL-RR output function. While there are “pathological” pairs of increments that induce “bad” additive constants that relate the two streams, the vast majority of pairs induce “good” additive constants that make the merely-distinct streams of LCG states into practically-independent output streams. Indeed, now the claim we once made about `PCG64` is actually true of `PCG64DXSM`: collisions are possible, but both streams have to simultaneously be both “close” in the 128 bit state space *and* “close” in the 127-bit increment space, so that would be less likely than the negligible chance of colliding in the 128-bit internal `SeedSequence` pool. The DXSM output function is more computationally intensive than XSL-RR, but some optimizations in the LCG more than make up for the performance hit on most machines, so `PCG64DXSM` is a good, safe upgrade. There are, of course, an infinite number of stronger output functions that one could consider, but most will have a greater computational cost, and the DXSM output function has now received many CPU cycles of testing via `PractRand` at this time.

Compatibility policy

`numpy.random` has a somewhat stricter compatibility policy than the rest of NumPy. Users of pseudorandomness often have use cases for being able to reproduce runs in fine detail given the same seed (so-called “stream compatibility”), and so we try to balance those needs with the flexibility to enhance our algorithms. [NEP 19](#) describes the evolution of this policy.

The main kind of compatibility that we enforce is stream-compatibility from run to run under certain conditions. If you create a `Generator` with the same `BitGenerator`, with the same seed, perform the same sequence of method calls with the same arguments, on the same build of `numpy`, in the same environment, on the same machine, you should get the same stream of numbers. Note that these conditions are very strict. There are a number of factors outside of NumPy’s control that limit our ability to guarantee much more than this. For example, different CPUs implement floating point arithmetic differently, and this can cause differences in certain edge cases that cascade to the rest of the stream. `Generator.multivariate_normal`, for another example, uses a matrix decomposition from `numpy.linalg`. Even on the same platform, a different build of `numpy` may use a different version of this matrix decomposition algorithm from the LAPACK that it links to, causing `Generator.multivariate_normal` to return completely different (but equally valid!) results. We strive to prefer algorithms that are more resistant to these effects, but this is always imperfect.

Note: Most of the `Generator` methods allow you to draw multiple values from a distribution as arrays. The requested size of this array is a parameter, for the purposes of the above policy. Calling `rng.random()` 5 times is not *guaranteed* to give the same numbers as `rng.random(5)`. We reserve the ability to decide to use different algorithms for different-sized blocks. In practice, this happens rarely.

Like the rest of NumPy, we generally maintain API source compatibility from version to version. If we *must* make an API-breaking change, then we will only do so with an appropriate deprecation period and warnings, according to [general NumPy policy](#).

Breaking stream-compatibility in order to introduce new features or improve performance in `Generator` or `default_rng` will be *allowed* with *caution*. Such changes will be considered features, and as such will be no faster than the standard release cadence of features (i.e. on `X.Y` releases, never `X.Y.Z`). Slowness will not be considered a bug for this purpose. Correctness bug fixes that break stream-compatibility can happen on bugfix releases, per usual, but developers should consider if they can wait until the next feature release. We encourage developers to strongly weight user’s pain from the break in stream-compatibility against the improvements. One example of a worthwhile improvement would be to change algorithms for a significant increase in performance, for example, moving from the [Box-Muller transform](#) method of Gaussian variate generation to the faster [Ziggurat algorithm](#). An example of a discouraged improvement would be tweaking the Ziggurat tables just a little bit for a small performance improvement.

Note: In particular, `default_rng` is allowed to change the default `BitGenerator` that it uses (again, with *caution* and plenty of advance warning).

In general, *BitGenerator* classes have stronger guarantees of version-to-version stream compatibility. This allows them to be a firmer building block for downstream users that need it. Their limited API surface makes it easier for them to maintain this compatibility from version to version. See the docstrings of each *BitGenerator* class for their individual compatibility guarantees.

The legacy *RandomState* and the *associated convenience functions* have a stricter version-to-version compatibility guarantee. For reasons outlined in NEP 19, we had made stronger promises about their version-to-version stability early in NumPy's development. There are still some limited use cases for this kind of compatibility (like generating data for tests), so we maintain as much compatibility as we can. There will be no more modifications to *RandomState*, not even to fix correctness bugs. There are a few gray areas where we can make minor fixes to keep *RandomState* working without segfaulting as NumPy's internals change, and some docstring fixes. However, the previously-mentioned caveats about the variability from machine to machine and build to build still apply to *RandomState* just as much as it does to *Generator*.

Features

Parallel random number generation

There are four main strategies implemented that can be used to produce repeatable pseudo-random numbers across multiple processes (local or distributed).

SeedSequence spawning

NumPy allows you to spawn new (with very high probability) independent *BitGenerator* and *Generator* instances via their `spawn()` method. This spawning is implemented by the *SeedSequence* used for initializing the bit generators random stream.

SeedSequence implements an algorithm to process a user-provided seed, typically as an integer of some size, and to convert it into an initial state for a *BitGenerator*. It uses hashing techniques to ensure that low-quality seeds are turned into high quality initial states (at least, with very high probability).

For example, *MT19937* has a state consisting of 624 `uint32` integers. A naive way to take a 32-bit integer seed would be to just set the last element of the state to the 32-bit seed and leave the rest 0s. This is a valid state for *MT19937*, but not a good one. The Mersenne Twister algorithm suffers if there are too many 0s. Similarly, two adjacent 32-bit integer seeds (i.e. 12345 and 12346) would produce very similar streams.

SeedSequence avoids these problems by using successions of integer hashes with good avalanche properties to ensure that flipping any bit in the input has about a 50% chance of flipping any bit in the output. Two input seeds that are very close to each other will produce initial states that are very far from each other (with very high probability). It is also constructed in such a way that you can provide arbitrary-sized integers or lists of integers. *SeedSequence* will take all of the bits that you provide and mix them together to produce however many bits the consuming *BitGenerator* needs to initialize itself.

These properties together mean that we can safely mix together the usual user-provided seed with simple incrementing counters to get *BitGenerator* states that are (to very high probability) independent of each other. We can wrap this together into an API that is easy to use and difficult to misuse. Note that while *SeedSequence* attempts to solve many of the issues related to user-provided small seeds, we still *recommend* using `secrets.randbits` to generate seeds with 128 bits of entropy to avoid the remaining biases introduced by human-chosen seeds.

```
from numpy.random import SeedSequence, default_rng

ss = SeedSequence(12345)

# Spawn off 10 child SeedSequences to pass to child processes.
child_seeds = ss.spawn(10)
streams = [default_rng(s) for s in child_seeds]
```

For convenience the direct use of `SeedSequence` is not necessary. The above streams can be spawned directly from a parent generator via `spawn`:

```
parent_rng = default_rng(12345)
streams = parent_rng.spawn(10)
```

Child objects can also spawn to make grandchildren, and so on. Each child has a `SeedSequence` with its position in the tree of spawned child objects mixed in with the user-provided seed to generate independent (with very high probability) streams.

```
grandchildren = streams[0].spawn(4)
```

This feature lets you make local decisions about when and how to split up streams without coordination between processes. You do not have to preallocate space to avoid overlapping or request streams from a common global service. This general “tree-hashing” scheme is **not unique to numpy** but not yet widespread. Python has increasingly-flexible mechanisms for parallelization available, and this scheme fits in very well with that kind of use.

Using this scheme, an upper bound on the probability of a collision can be estimated if one knows the number of streams that you derive. `SeedSequence` hashes its inputs, both the seed and the spawn-tree-path, down to a 128-bit pool by default. The probability that there is a collision in that pool, pessimistically-estimated ⁽¹⁾, will be about $n^2 * 2^{-128}$ where n is the number of streams spawned. If a program uses an aggressive million streams, about 2^{20} , then the probability that at least one pair of them are identical is about 2^{-88} , which is in solidly-ignorable territory ⁽²⁾.

Sequence of integer seeds

As discussed in the previous section, `SeedSequence` can not only take an integer seed, it can also take an arbitrary-length sequence of (non-negative) integers. If one exercises a little care, one can use this feature to design *ad hoc* schemes for getting safe parallel PRNG streams with similar safety guarantees as spawning.

For example, one common use case is that a worker process is passed one root seed integer for the whole calculation and also an integer worker ID (or something more granular like a job ID, batch ID, or something similar). If these IDs are created deterministically and uniquely, then one can derive reproducible parallel PRNG streams by combining the ID and the root seed integer in a list.

```
# default_rng() and each of the BitGenerators use SeedSequence underneath, so
# they all accept sequences of integers as seeds the same way.
from numpy.random import default_rng

def worker(root_seed, worker_id):
    rng = default_rng([worker_id, root_seed])
    # Do work ...

root_seed = 0x8c3c010cb4754c905776bdac5ee7501
results = [worker(root_seed, worker_id) for worker_id in range(10)]
```

This can be used to replace a number of unsafe strategies that have been used in the past which try to combine the root seed and the ID back into a single integer seed value. For example, it is common to see users add the worker ID to the root seed, especially with the legacy `RandomState` code.

¹ The algorithm is carefully designed to eliminate a number of possible ways to collide. For example, if one only does one level of spawning, it is guaranteed that all states will be unique. But it's easier to estimate the naive upper bound on a napkin and take comfort knowing that the probability is actually lower.

² In this calculation, we can mostly ignore the amount of numbers drawn from each stream. See *Upgrading PCG64 with PCG64DXSM* for the technical details about *PCG64*. The other PRNGs we provide have some extra protection built in that avoids overlaps if the `SeedSequence` pools differ in the slightest bit. *PCG64DXSM* has 2^{127} separate cycles determined by the seed in addition to the position in the 2^{128} long period for each cycle, so one has to both get on or near the same cycle *and* seed a nearby position in the cycle. *Philox* has completely independent cycles determined by the seed. *SFC64* incorporates a 64-bit counter so every unique seed is at least 2^{64} iterations away from any other seed. And finally, *MT19937* has just an unimaginably huge period. Getting a collision internal to `SeedSequence` is the way a failure would be observed.

```
# UNSAFE! Do not do this!
worker_seed = root_seed + worker_id
rng = np.random.RandomState(worker_seed)
```

It is true that for any one run of a parallel program constructed this way, each worker will have distinct streams. However, it is quite likely that multiple invocations of the program with different seeds will get overlapping sets of worker seeds. It is not uncommon (in the author's self-experience) to change the root seed merely by an increment or two when doing these repeat runs. If the worker seeds are also derived by small increments of the worker ID, then subsets of the workers will return identical results, causing a bias in the overall ensemble of results.

Combining the worker ID and the root seed as a list of integers eliminates this risk. Lazy seeding practices will still be fairly safe.

This scheme does require that the extra IDs be unique and deterministically created. This may require coordination between the worker processes. It is recommended to place the varying IDs *before* the unvarying root seed. `spawn` appends integers after the user-provided seed, so if you might be mixing both this *ad hoc* mechanism and spawning, or passing your objects down to library code that might be spawning, then it is a little bit safer to prepend your worker IDs rather than append them to avoid a collision.

```
# Good.
worker_seed = [worker_id, root_seed]

# Less good. It will *work*, but it's less flexible.
worker_seed = [root_seed, worker_id]
```

With those caveats in mind, the safety guarantees against collision are about the same as with spawning, discussed in the previous section. The algorithmic mechanisms are the same.

Independent streams

`Philox` is a counter-based RNG based which generates values by encrypting an incrementing counter using weak cryptographic primitives. The seed determines the key that is used for the encryption. Unique keys create unique, independent streams. `Philox` lets you bypass the seeding algorithm to directly set the 128-bit key. Similar, but different, keys will still create independent streams.

```
import secrets
from numpy.random import Philox

# 128-bit number as a seed
root_seed = secrets.getrandbits(128)
streams = [Philox(key=root_seed + stream_id) for stream_id in range(10)]
```

This scheme does require that you avoid reusing stream IDs. This may require coordination between the parallel processes.

Jumping the BitGenerator state

`jumped` advances the state of the BitGenerator *as-if* a large number of random numbers have been drawn, and returns a new instance with this state. The specific number of draws varies by BitGenerator, and ranges from 2^{64} to 2^{128} . Additionally, the *as-if* draws also depend on the size of the default random number produced by the specific BitGenerator. The BitGenerators that support `jumped`, along with the period of the BitGenerator, the size of the jump and the bits in the default unsigned random are listed below.

BitGenerator	Period	Jump Size	Bits per Draw
<i>MT19937</i>	$2^{19937} - 1$	2^{128}	32
<i>PCG64</i>	2^{128}	2^{127} ⁽³⁾	64
<i>PCG64DXSM</i>	2^{128}	2^{127} (Page 357, 3)	64
<i>Philox</i>	2^{256}	2^{128}	64

`jumped` can be used to produce long blocks which should be long enough to not overlap.

```
import secrets
from numpy.random import PCG64

seed = secrets.getrandbits(128)
blocked_rng = []
rng = PCG64(seed)
for i in range(10):
    blocked_rng.append(rng.jumped(i))
```

When using `jumped`, one does have to take care not to jump to a stream that was already used. In the above example, one could not later use `blocked_rng[0].jumped()` as it would overlap with `blocked_rng[1]`. Like with the independent streams, if the main process here wants to split off 10 more streams by jumping, then it needs to start with `range(10, 20)`, otherwise it would recreate the same streams. On the other hand, if you carefully construct the streams, then you are guaranteed to have streams that do not overlap.

Multithreaded generation

The four core distributions (*random*, *standard_normal*, *standard_exponential*, and *standard_gamma*) all allow existing arrays to be filled using the `out` keyword argument. Existing arrays need to be contiguous and well-behaved (writable and aligned). Under normal circumstances, arrays created using the common constructors such as *numpy.empty* will satisfy these requirements.

See also:

Thread Safety for general information about thread safety in NumPy.

This example makes use of `concurrent.futures` to fill an array using multiple threads. Threads are long-lived so that repeated calls do not require any additional overheads from thread creation.

The random numbers generated are reproducible in the sense that the same seed will produce the same outputs, given that the number of threads does not change.

```
from numpy.random import default_rng, SeedSequence
import multiprocessing
import concurrent.futures
import numpy as np

class MultithreadedRNG:
    def __init__(self, n, seed=None, threads=None):
        if threads is None:
            threads = multiprocessing.cpu_count()
        self.threads = threads
```

(continues on next page)

³ The jump size is $(\phi - 1) * 2^{128}$ where ϕ is the golden ratio. As the jumps wrap around the period, the actual distances between neighboring streams will slowly grow smaller than the jump size, but using the golden ratio this way is a classic method of constructing a low-discrepancy sequence that spreads out the states around the period optimally. You will not be able to jump enough to make those distances small enough to overlap in your lifetime.

(continued from previous page)

```

seq = SeedSequence(seed)
self._random_generators = [default_rng(s)
                           for s in seq.spawn(threads)]

self.n = n
self.executor = concurrent.futures.ThreadPoolExecutor(threads)
self.values = np.empty(n)
self.step = np.ceil(n / threads).astype(np.int_)

def fill(self):
    def _fill(random_state, out, first, last):
        random_state.standard_normal(out=out[first:last])

    futures = {}
    for i in range(self.threads):
        args = (_fill,
               self._random_generators[i],
               self.values,
               i * self.step,
               (i + 1) * self.step)
        futures[self.executor.submit(*args)] = i
    concurrent.futures.wait(futures)

def __del__(self):
    self.executor.shutdown(False)

```

The multithreaded random number generator can be used to fill an array. The `values` attributes shows the zero-value before the fill and the random value after.

```

In [2]: mrng = MultithreadedRNG(10000000, seed=12345)
...: print(mrng.values[-1])
Out[2]: 0.0

In [3]: mrng.fill()
...: print(mrng.values[-1])
Out[3]: 2.4545724517479104

```

The time required to produce using multiple threads can be compared to the time required to generate using a single thread.

```

In [4]: print(mrng.threads)
...: %timeit mrng.fill()

Out[4]: 4
...: 32.8 ms ± 2.71 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

```

The single threaded call directly uses the BitGenerator.

```

In [5]: values = np.empty(10000000)
...: rg = default_rng()
...: %timeit rg.standard_normal(out=values)

Out[5]: 99.6 ms ± 222 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

```

The gains are substantial and the scaling is reasonable even for arrays that are only moderately large. The gains are even larger when compared to a call that does not use an existing array due to array creation overhead.

```
In [6]: rg = default_rng()
...: %timeit rg.standard_normal(10000000)
```

```
Out[6]: 125 ms ± 309 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)
```

Note that if `threads` is not set by the user, it will be determined by `multiprocessing.cpu_count()`.

```
In [7]: # simulate the behavior for `threads=None`, if the machine had only one thread
...: mrng = MultithreadedRNG(10000000, seed=12345, threads=1)
...: print(mrng.values[-1])
Out[7]: 1.1800150052158556
```

What's new or different

NumPy 1.17.0 introduced *Generator* as an improved replacement for the *legacy RandomState*. Here is a quick comparison of the two implementations.

Feature	Older Equivalent	Notes
<i>Generator</i>	<i>RandomState</i>	<i>Generator</i> requires a stream source, called a <i>BitGenerator</i> . A number of these are provided. <i>RandomState</i> uses the Mersenne Twister <i>MT19937</i> by default, but can also be instantiated with any <i>BitGenerator</i> .
<i>random</i>	<i>random</i>	Access the values in a <i>BitGenerator</i> , convert them to <code>float64</code> in the interval <code>[0.0., 1.0)</code> . In addition to the <code>size</code> kwarg, now supports <code>dtype='d'</code> or <code>dtype='f'</code> , and an <code>out</code> kwarg to fill a user-supplied array. Many other distributions are also supported.
<i>integers</i>	<i>randint</i> , <i>rand</i>	Use the <code>endpoint</code> kwarg to adjust the inclusion or exclusion of the high interval endpoint.
	<i>randint</i> , <i>rand</i>	
	<i>dom_integ</i>	

- The normal, exponential and gamma generators use 256-step Ziggurat methods which are 2-10 times faster than NumPy's default implementation in *standard_normal*, *standard_exponential* or *standard_gamma*. Because of the change in algorithms, it is not possible to reproduce the exact random values using *Generator* for these distributions or any distribution method that relies on them.

```
In [1]: import numpy.random
```

```
In [2]: rng = np.random.default_rng()
```

```
In [3]: %timeit -n 1 rng.standard_normal(100000)
...: %timeit -n 1 numpy.random.standard_normal(100000)
...:
```

```
1.04 ms +- 24.2 us per loop (mean +- std. dev. of 7 runs, 1 loop each)
```

```
1.75 ms +- 8.26 us per loop (mean +- std. dev. of 7 runs, 1 loop each)
```

```
In [4]: %timeit -n 1 rng.standard_exponential(100000)
...: %timeit -n 1 numpy.random.standard_exponential(100000)
...:
```

```
490 us +- 4.59 us per loop (mean +- std. dev. of 7 runs, 1 loop each)
```

```
1.26 ms +- 14.2 us per loop (mean +- std. dev. of 7 runs, 1 loop each)
```

```
In [5]: %timeit -n 1 rng.standard_gamma(3.0, 100000)
...: %timeit -n 1 numpy.random.standard_gamma(3.0, 100000)
...:
1.86 ms +- 9.67 us per loop (mean +- std. dev. of 7 runs, 1 loop each)
3.44 ms +- 17.1 us per loop (mean +- std. dev. of 7 runs, 1 loop each)
```

- `integers` is now the canonical way to generate integer random numbers from a discrete uniform distribution. This replaces both `randint` and the deprecated `random_integers`.
- The `rand` and `randn` methods are only available through the legacy `RandomState`.
- `Generator.random` is now the canonical way to generate floating-point random numbers, which replaces `RandomState.random_sample`, `sample`, and `ranf`, all of which were aliases. This is consistent with Python's `random.random`.
- All bit generators can produce doubles, uint64s and uint32s via CTypes (`ctypes`) and CFFI (`cffi`). This allows these bit generators to be used in numba.
- The bit generators can be used in downstream projects via Cython.
- All bit generators use `SeedSequence` to *convert seed integers to initialized states*.
- Optional dtype argument that accepts `np.float32` or `np.float64` to produce either single or double precision uniform random variables for select distributions. `integers` accepts a dtype argument with any signed or unsigned integer dtype.
 - Uniforms (`random` and `integers`)
 - Normals (`standard_normal`)
 - Standard Gammas (`standard_gamma`)
 - Standard Exponentials (`standard_exponential`)

```
In [6]: rng = np.random.default_rng()

In [7]: rng.random(3, dtype=np.float64)
Out[7]: array([0.76759948, 0.88825294, 0.21580722])

In [8]: rng.random(3, dtype=np.float32)
Out[8]: array([0.01490843, 0.74982375, 0.6904811 ], dtype=float32)

In [9]: rng.integers(0, 256, size=3, dtype=np.uint8)
Out[9]: array([ 94, 145, 119], dtype=uint8)
```

- Optional out argument that allows existing arrays to be filled for select distributions
 - Uniforms (`random`)
 - Normals (`standard_normal`)
 - Standard Gammas (`standard_gamma`)
 - Standard Exponentials (`standard_exponential`)

This allows multithreading to fill large arrays in chunks using suitable BitGenerators in parallel.

```
In [10]: rng = np.random.default_rng()

In [11]: existing = np.zeros(4)

In [12]: rng.random(out=existing[:2])
```

(continues on next page)

(continued from previous page)

```
Out [12]: array([0.09459523, 0.99734979])

In [13]: print(existing)
[0.09459523 0.99734979 0.          0.          ]
```

- Optional `axis` argument for methods like `choice`, `permutation` and `shuffle` that controls which axis operation is performed over for multi-dimensional arrays.

```
In [14]: rng = np.random.default_rng()

In [15]: a = np.arange(12).reshape((3, 4))

In [16]: a
Out [16]:
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11]])

In [17]: rng.choice(a, axis=1, size=5)
Out [17]:
array([[ 2,  2,  1,  0,  1],
       [ 6,  6,  5,  4,  5],
       [10, 10,  9,  8,  9]])

In [18]: rng.shuffle(a, axis=1)           # Shuffle in-place

In [19]: a
Out [19]:
array([[ 2,  3,  1,  0],
       [ 6,  7,  5,  4],
       [10, 11,  9,  8]])
```

- Added a method to sample from the complex normal distribution (`complex_normal`)

Performance

Recommendation

The recommended generator for general use is `PCG64` or its upgraded variant `PCG64DXSM` for heavily-parallel use cases. They are statistically high quality, full-featured, and fast on most platforms, but somewhat slow when compiled for 32-bit processes. See [Upgrading PCG64 with PCG64DXSM](#) for details on when heavy parallelism would indicate using `PCG64DXSM`.

`Philox` is fairly slow, but its statistical properties have very high quality, and it is easy to get an assuredly-independent stream by using unique keys. If that is the style you wish to use for parallel streams, or you are porting from another system that uses that style, then `Philox` is your choice.

`SFC64` is statistically high quality and very fast. However, it lacks jumpability. If you are not using that capability and want lots of speed, even on 32-bit processes, this is your choice.

`MT19937` fails some statistical tests and is not especially fast compared to modern PRNGs. For these reasons, we mostly do not recommend using it on its own, only through the legacy `RandomState` for reproducing old results. That said, it has a very long history as a default in many systems.

Timings

The timings below are the time in ns to produce 1 random value from a specific distribution. The original `MT19937` generator is much slower since it requires 2 32-bit values to equal the output of the faster generators.

Integer performance has a similar ordering.

The pattern is similar for other, more complex generators. The normal performance of the legacy `RandomState` generator is much lower than the other since it uses the Box-Muller transform rather than the Ziggurat method. The performance gap for Exponentials is also large due to the cost of computing the log function to invert the CDF. The column labeled MT19973 uses the same 32-bit generator as `RandomState` but produces random variates using `Generator`.

	MT19937	PCG64	PCG64DXSM	Philox	SFC64	Random-State
32-bit Unsigned Ints	3.3	1.9	2.0	3.3	1.8	3.1
64-bit Unsigned Ints	5.6	3.2	2.9	4.9	2.5	5.5
Uniforms	5.9	3.1	2.9	5.0	2.6	6.0
Normals	13.9	10.8	10.5	12.0	8.3	56.8
Exponentials	9.1	6.0	5.8	8.1	5.4	63.9
Gammas	37.2	30.8	28.9	34.0	27.5	77.0
Binomials	21.3	17.4	17.6	19.3	15.6	21.4
Laplaces	73.2	72.3	76.1	73.0	72.3	82.5
Poissons	111.7	103.4	100.5	109.4	90.7	115.2

The next table presents the performance in percentage relative to values generated by the legacy generator, `RandomState (MT19937())`. The overall performance was computed using a geometric mean.

	MT19937	PCG64	PCG64DXSM	Philox	SFC64
32-bit Unsigned Ints	96	162	160	96	175
64-bit Unsigned Ints	97	171	188	113	218
Uniforms	102	192	206	121	233
Normals	409	526	541	471	684
Exponentials	701	1071	1101	784	1179
Gammas	207	250	266	227	281
Binomials	100	123	122	111	138
Laplaces	113	114	108	113	114
Poissons	103	111	115	105	127
Overall	159	219	225	174	251

Note: All timings were taken using Linux on an AMD Ryzen 9 3900X processor.

Performance on different operating systems

Performance differs across platforms due to compiler and hardware availability (e.g., register width) differences. The default bit generator has been chosen to perform well on 64-bit platforms. Performance on 32-bit operating systems is very different.

The values reported are normalized relative to the speed of MT19937 in each table. A value of 100 indicates that the performance matches the MT19937. Higher values indicate improved performance. These values cannot be compared across tables.

64-bit Linux

Distribution	MT19937	PCG64	PCG64DXSM	Philox	SFC64
32-bit Unsigned Ints	100	168	166	100	182
64-bit Unsigned Ints	100	176	193	116	224
Uniforms	100	188	202	118	228
Normals	100	128	132	115	167
Exponentials	100	152	157	111	168
Overall	100	161	168	112	192

64-bit Windows

The relative performance on 64-bit Linux and 64-bit Windows is broadly similar with the notable exception of the Philox generator.

Distribution	MT19937	PCG64	PCG64DXSM	Philox	SFC64
32-bit Unsigned Ints	100	155	131	29	150
64-bit Unsigned Ints	100	157	143	25	154
Uniforms	100	151	144	24	155
Normals	100	129	128	37	150
Exponentials	100	150	145	28	159
Overall	100	148	138	28	154

32-bit Windows

The performance of 64-bit generators on 32-bit Windows is much lower than on 64-bit operating systems due to register width. MT19937, the generator that has been in NumPy since 2005, operates on 32-bit integers.

Distribution	MT19937	PCG64	PCG64DXSM	Philox	SFC64
32-bit Unsigned Ints	100	24	34	14	57
64-bit Unsigned Ints	100	21	32	14	74
Uniforms	100	21	34	16	73
Normals	100	36	57	28	101
Exponentials	100	28	44	20	88
Overall	100	25	39	18	77

Note: Linux timings used Ubuntu 20.04 and GCC 9.3.0. Windows timings were made on Windows 10 using Microsoft C/C++ Optimizing Compiler Version 19 (Visual Studio 2019). All timings were produced on an AMD Ryzen 9 3900X processor.

C API for random

Access to various distributions below is available via Cython or C-wrapper libraries like CFFI. All the functions accept a *bitgen_t* as their first argument. To access these from Cython or C, you must link with the `npyrandom` static library which is part of the NumPy distribution, located in `numpy/random/lib`. Note that you must *also* link with `npymath`, see [Linking against the core math library in an extension](#).

type *bitgen_t*

The *bitgen_t* holds the current state of the BitGenerator and pointers to functions that return standard C types while advancing the state.

```
struct bitgen:
    void *state
    npy_uint64 (*next_uint64)(void *st) nogil
    uint32_t (*next_uint32)(void *st) nogil
    double (*next_double)(void *st) nogil
    npy_uint64 (*next_raw)(void *st) nogil

typedef bitgen bitgen_t
```

See [Extending](#) for examples of using these functions.

The functions are named with the following conventions:

- “standard” refers to the reference values for any parameters. For instance “standard_uniform” means a uniform distribution on the interval 0.0 to 1.0
- “fill” functions will fill the provided `out` with `cnt` values.
- The functions without “standard” in their name require additional parameters to describe the distributions.
- Functions with `inv` in their name are based on the slower inverse method instead of a ziggurat lookup algorithm, which is significantly faster. The non-ziggurat variants are used in corner cases and for legacy compatibility.

double **random_standard_uniform** (*bitgen_t* *bitgen_state)

void **random_standard_uniform_fill** (*bitgen_t* *bitgen_state, *npy_intp* cnt, double *out)

double **random_standard_exponential** (*bitgen_t* *bitgen_state)

void **random_standard_exponential_fill** (*bitgen_t* *bitgen_state, *npy_intp* cnt, double *out)

Generate a single integer

numpy_int64 **random_positive_int64** (*bitgen_t* *bitgen_state)

numpy_int32 **random_positive_int32** (*bitgen_t* *bitgen_state)

numpy_int64 **random_positive_int** (*bitgen_t* *bitgen_state)

```
numpy.uint64 random_uint (bitgen_t *bitgen_state)
```

Generate random uint64 numbers in closed interval [off, off + rng].

```
numpy.uint64 random_bounded_uint64 (bitgen_t *bitgen_state, numpy.uint64 off, numpy.uint64 rng, numpy.uint64 mask,
                                     bool use_masked)
```

Extending

The *BitGenerators* have been designed to be extendable using standard tools for high-performance Python – numba and Cython. The *Generator* object can also be used with user-provided *BitGenerators* as long as these export a small set of required functions.

Numba

Numba can be used with either *CTypes* or *CFFI*. The current iteration of the *BitGenerators* all export a small set of functions through both interfaces.

This example shows how Numba can be used to produce Gaussian samples using a pure Python implementation which is then compiled. The random numbers are provided by `ctypes.next_double`.

```
from timeit import timeit

import numba as nb

import numpy as np
from numpy.random import PCG64

bit_gen = PCG64()
next_d = bit_gen.cffi.next_double
state_addr = bit_gen.cffi.state_address

def normals(n, state):
    out = np.empty(n)
    for i in range((n + 1) // 2):
        x1 = 2.0 * next_d(state) - 1.0
        x2 = 2.0 * next_d(state) - 1.0
        r2 = x1 * x1 + x2 * x2
        while r2 >= 1.0 or r2 == 0.0:
            x1 = 2.0 * next_d(state) - 1.0

    return rg.normal(size=n)

# Check that the functions work
r1 = numbacall()
r2 = numpycall()
assert r1.shape == (n,)
assert r1.shape == r2.shape

t1 = timeit(numbacall, number=1000)
print(f'{t1:.2f} secs for {n} PCG64 (Numba/PCG64) gaussian randoms')
t2 = timeit(numpycall, number=1000)
print(f'{t2:.2f} secs for {n} PCG64 (NumPy/PCG64) gaussian randoms')

```

Both CTypes and CFFI allow the more complicated distributions to be used directly in Numba after compiling the file `distributions.c` into a DLL or so. An example showing the use of a more complicated distribution is in the [Examples](#) section below.

Cython

Cython can be used to unpack the PyCapsule provided by a [BitGenerator](#). This example uses [PCG64](#) and the example from above. The usual caveats for writing high-performance code using Cython – removing bounds checks and wrap around, providing array alignment information – still apply.

```

#cython: language_level=3
"""
This file shows how to use a BitGenerator to create a distribution.
"""
import numpy as np
cimport numpy as np
cimport cython
from cpython.pycapsule cimport PyCapsule_IsValid, PyCapsule_GetPointer
from libc.stdint cimport uint16_t, uint64_t
from numpy.random cimport bitgen_t
from numpy.random import PCG64
from numpy.random.c_distributions cimport (
    random_standard_uniform_fill, random_standard_uniform_fill_f)

np.import_array()

@cython.boundscheck(False)
@cython.wraparound(False)
def uniforms(Py_ssize_t n):
    """
    Create an array of `n` uniformly distributed doubles.
    A 'real' distribution would want to process the values into
    some non-uniform distribution
    """

```

(continues on next page)

(continued from previous page)

```

"""
cdef Py_ssize_t i
cdef bitgen_t *rng
cdef const char *capsule_name = "BitGenerator"
cdef double[:,1] random_values

x = PCG64()
capsule = x.capsule
# Optional check that the capsule is from a BitGenerator
if not PyCapsule_IsValid(capsule, capsule_name):
    raise ValueError("Invalid pointer to anon_func_state")
# Cast the pointer
rng = <bitgen_t *> PyCapsule_GetPointer(capsule, capsule_name)

            random_standard_uniform_fill(rng, n, <double*>np.PyArray_DATA(randoms))
    else:
        raise TypeError('Unsupported dtype %r for random' % _dtype)
    return randoms

```

See [Extending numpy.random via Cython](#) for the complete listings of these examples and a minimal `setup.py` to build the c-extension modules.

CFFI

CFFI can be used to directly access the functions in `include/numpy/random/distributions.h`. Some “mas-saging” of the header file is required:

```

"""
Use cffi to access any of the underlying C functions from distributions.h
"""
import os

import cffi

import numpy as np

```

(continues on next page)

(continued from previous page)

```

from .parse import parse_distributions_h

ffi = cffi.FFI()

inc_dir = os.path.join(np.get_include(), 'numpy')

# Basic numpy types
ffi.cdef('''
    typedef intptr_t npy_intp;
    typedef unsigned char npy_bool;
''')

parse_distributions_h(ffi, inc_dir)

```

Once the header is parsed by `ffi.cdef`, the functions can be accessed directly from the `_generator` shared object, using the `BitGenerator.cffi` interface.

```

lib = ffi.dlopen(np.random._generator.__file__)

# Compare the distributions.h random_standard_normal_fill to
# Generator.standard_random
bit_gen = np.random.PCG64()
rng = np.random.Generator(bit_gen)
state = bit_gen.state

interface = rng.bit_generator.cffi
n = 100
vals_cffi = ffi.new(f'double[{n}]')
lib.random_standard_normal_fill(interface.bit_generator, n, vals_cffi)

# reset the state
bit_gen.state = state

vals = rng.standard_normal(n)

for i in range(n):
    assert vals[i] == vals_cffi[i]

```

New BitGenerators

Generator can be used with user-provided *BitGenerators*. The simplest way to write a new *BitGenerator* is to examine the `pyx` file of one of the existing *BitGenerators*. The key structure that must be provided is the capsule which contains a `PyCapsule` to a struct pointer of type `bitgen_t`,

```

typedef struct bitgen {
    void *state;
    uint64_t (*next_uint64)(void *st);
    uint32_t (*next_uint32)(void *st);
    double (*next_double)(void *st);
    uint64_t (*next_raw)(void *st);
} bitgen_t;

```

which provides 5 pointers. The first is an opaque pointer to the data structure used by the *BitGenerators*. The next

three are function pointers which return the next 64- and 32-bit unsigned integers, the next random double and the next raw value. This final function is used for testing and so can be set to the next 64-bit unsigned integer function if not needed. Functions inside *Generator* use this structure as in

```
bitgen_state->next_uint64(bitgen_state->state)
```

Examples

Extending via Numba

```
from timeit import timeit

import numba as nb

import numpy as np
from numpy.random import PCG64

bit_gen = PCG64()
next_d = bit_gen.cffi.next_double
state_addr = bit_gen.cffi.state_address

def normals(n, state):
    out = np.empty(n)
    for i in range((n + 1) // 2):
        x1 = 2.0 * next_d(state) - 1.0
        x2 = 2.0 * next_d(state) - 1.0
        r2 = x1 * x1 + x2 * x2
        while r2 >= 1.0 or r2 == 0.0:
            x1 = 2.0 * next_d(state) - 1.0
            x2 = 2.0 * next_d(state) - 1.0
            r2 = x1 * x1 + x2 * x2
        f = np.sqrt(-2.0 * np.log(r2) / r2)
        out[2 * i] = f * x1
        if 2 * i + 1 < n:
            out[2 * i + 1] = f * x2
    return out

# Compile using Numba
normalsj = nb.jit(normals, nopython=True)
# Must use state address not state with numba
n = 10000

vals = rng.standard_normal(n)

for i in range(n):
    assert vals[i] == vals_cffi[i]

```

Original Source of the Generator and BitGenerators

This package was developed independently of NumPy and was integrated in version 1.17.0. The original repo is at <https://github.com/bashtage/randomgen>.

String functionality

The `numpy.strings` module provides a set of universal functions operating on arrays of type `numpy.str_` or `numpy.bytes_`. For example,

```

>>> np.strings.add(["num", "doc"], ["py", "umentation"])
array(['numpy', 'documentation'], dtype='<U13')

```

These universal functions are also used in `numpy.char`, which provides the `numpy.char.chararray` array subclass, in order for those routines to get the performance benefits as well.

Note: Prior to NumPy 2.0, all string functionality was in `numpy.char`, which only operated on fixed-width strings. That module will not be getting updates and will be deprecated at some point in the future.

String operations

<code>add(x1, x2, /[, out, where, casting, order, ...])</code>	Add arguments element-wise.
<code>center(a, width[, fillchar])</code>	Return a copy of <i>a</i> with its elements centered in a string of length <i>width</i> .
<code>capitalize(a)</code>	Return a copy of <i>a</i> with only the first character of each element capitalized.
<code>decode(a[, encoding, errors])</code>	Calls <code>bytes.decode</code> element-wise.
<code>encode(a[, encoding, errors])</code>	Calls <code>str.encode</code> element-wise.
<code>expandtabs(a[, tabsize])</code>	Return a copy of each string element where all tab characters are replaced by one or more spaces.
<code>ljust(a, width[, fillchar])</code>	Return an array with the elements of <i>a</i> left-justified in a string of length <i>width</i> .
<code>lower(a)</code>	Return an array with the elements converted to lowercase.
<code>lstrip(a[, chars])</code>	For each element in <i>a</i> , return a copy with the leading characters removed.
<code>mod(a, values)</code>	Return $(a \% i)$, that is pre-Python 2.6 string formatting (interpolation), element-wise for a pair of array_likes of str or unicode.
<code>multiply(a, i)</code>	Return $(a * i)$, that is string multiple concatenation, element-wise.
<code>partition(a, sep)</code>	Partition each element in <i>a</i> around <i>sep</i> .
<code>replace(a, old, new[, count])</code>	For each element in <i>a</i> , return a copy of the string with occurrences of substring <i>old</i> replaced by <i>new</i> .
<code>rjust(a, width[, fillchar])</code>	Return an array with the elements of <i>a</i> right-justified in a string of length <i>width</i> .
<code>rpartition(a, sep)</code>	Partition (split) each element around the right-most separator.
<code>rstrip(a[, chars])</code>	For each element in <i>a</i> , return a copy with the trailing characters removed.
<code>slice(a[, start, stop, step])</code>	Slice the strings in <i>a</i> by slices specified by <i>start</i> , <i>stop</i> , <i>step</i> .
<code>strip(a[, chars])</code>	For each element in <i>a</i> , return a copy with the leading and trailing characters removed.
<code>swapcase(a)</code>	Return element-wise a copy of the string with uppercase characters converted to lowercase and vice versa.
<code>title(a)</code>	Return element-wise title cased version of string or unicode.
<code>translate(a, table[, deletechars])</code>	For each element in <i>a</i> , return a copy of the string where all characters occurring in the optional argument <i>deletechars</i> are removed, and the remaining characters have been mapped through the given translation table.
<code>upper(a)</code>	Return an array with the elements converted to uppercase.
<code>zfill(a, width)</code>	Return the numeric string left-filled with zeros.

```
strings.add(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'add'>
```

Add arguments element-wise.

Parameters

x1, x2

[array_like] The arrays to be added. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**add**

[ndarray or scalar] The sum of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

Notes

Equivalent to $x1 + x2$ in terms of array broadcasting.

Examples

```
>>> import numpy as np
>>> np.add(1.0, 4.0)
5.0
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> np.add(x1, x2)
array([[ 0.,  2.,  4.],
       [ 3.,  5.,  7.],
       [ 6.,  8., 10.]])
```

The `+` operator can be used as a shorthand for `np.add` on ndarrays.

```
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> x1 + x2
array([[ 0.,  2.,  4.],
       [ 3.,  5.,  7.],
       [ 6.,  8., 10.]])
```

`strings.center(a, width, fillchar='')`

Return a copy of *a* with its elements centered in a string of length *width*.

Parameters**a**

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

width

[array_like, with any integer dtype] The length of the resulting strings, unless `width < str_len(a)`.

fillchar

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Optional padding character to use (default is space).

Returns**out**

[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.center`

Notes

While it is possible for `a` and `fillchar` to have different dtypes, passing a non-ASCII character in `fillchar` when `a` is of dtype “S” is not allowed, and a `ValueError` is raised.

Examples

```
>>> import numpy as np
>>> c = np.array(['a1b2', '1b2a', 'b2a1', '2a1b']); c
array(['a1b2', '1b2a', 'b2a1', '2a1b'], dtype='<U4')
>>> np.strings.center(c, width=9)
array(['   a1b2   ', '   1b2a   ', '   b2a1   ', '   2a1b   '], dtype='<U9')
>>> np.strings.center(c, width=9, fillchar='*')
array(['***a1b2***', '***1b2a***', '***b2a1***', '***2a1b***'], dtype='<U9')
>>> np.strings.center(c, width=1)
array(['a1b2', '1b2a', 'b2a1', '2a1b'], dtype='<U4')
```

`strings.capitalize(a)`

Return a copy of `a` with only the first character of each element capitalized.

Calls `str.capitalize` element-wise.

For byte strings, this method is locale-dependent.

Parameters**a**

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array of strings to capitalize.

Returns**out**

[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.capitalize`

Examples

```
>>> import numpy as np
>>> c = np.array(['a1b2', '1b2a', 'b2a1', '2a1b'], 'S4'); c
array(['a1b2', '1b2a', 'b2a1', '2a1b'],
      dtype='|S4')
>>> np.strings.capitalize(c)
array(['A1b2', '1b2a', 'B2a1', '2a1b'],
      dtype='|S4')
```

`strings.decode` (*a*, *encoding=None*, *errors=None*)

Calls `bytes.decode` element-wise.

The set of available codecs comes from the Python standard library, and may be extended at runtime. For more information, see the `codecs` module.

Parameters

- a**
[array_like, with `bytes_` dtype]
- encoding**
[str, optional] The name of an encoding
- errors**
[str, optional] Specifies how to handle encoding errors

Returns

- out**
[ndarray]

See also:

`bytes.decode`

Notes

The type of the result will depend on the encoding specified.

Examples

```
>>> import numpy as np
>>> c = np.array([b'\x81\xc1\x81\xc1\x81\xc1', b'@@\x81\xc1@@',
...               b'\x81\x82\xc2\xc1\xc2\x82\x81'])
>>> c
array([b'\x81\xc1\x81\xc1\x81\xc1', b'@@\x81\xc1@@',
      b'\x81\x82\xc2\xc1\xc2\x82\x81'], dtype='|S7')
>>> np.strings.decode(c, encoding='cp037')
array(['aAaAaA', '  aA  ', 'abBABba'], dtype='<U7')
```

`strings.encode` (*a*, *encoding=None*, *errors=None*)

Calls `str.encode` element-wise.

The set of available codecs comes from the Python standard library, and may be extended at runtime. For more information, see the `codecs` module.

Parameters

a
[array_like, with `StringDType` or `str_ dtype`]

encoding
[str, optional] The name of an encoding

errors
[str, optional] Specifies how to handle encoding errors

Returns

out
[ndarray]

See also:

`str.encode`

Notes

The type of the result will depend on the encoding specified.

Examples

```
>>> import numpy as np
>>> a = np.array(['aAaAaA', ' aA ', 'abBABba'])
>>> np.strings.encode(a, encoding='cp037')
array([b'\xc3\x84\xc3\x84\xc3\x84', b'@\xc3\x84@',
       b'\xc3\x84\xc3\x84\xc3\x84'], dtype='|S7')
```

`strings.expandtabs(a, tabsize=8)`

Return a copy of each string element where all tab characters are replaced by one or more spaces.

Calls `str.expandtabs` element-wise.

Return a copy of each string element where all tab characters are replaced by one or more spaces, depending on the current column and the given *tabsize*. The column number is reset to zero after each newline occurring in the string. This doesn't understand other non-printing characters or escape sequences.

Parameters

a
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array

tabsize
[int, optional] Replace tabs with *tabsize* number of spaces. If not given defaults to 8 spaces.

Returns

out
[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input type

See also:

`str.expandtabs`

Examples

```
>>> import numpy as np
>>> a = np.array(['      Hello   world'])
>>> np.strings.expandtabs(a, tabsize=4)
array(['      Hello   world'], dtype='<U21')
```

`strings.ljust(a, width, fillchar='')`

Return an array with the elements of *a* left-justified in a string of length *width*.

Parameters

a

[array-like, with StringDType, bytes_, or str_ dtype]

width

[array_like, with any integer dtype] The length of the resulting strings, unless `width < str_len(a)`.

fillchar

[array-like, with StringDType, bytes_, or str_ dtype] Optional character to use for padding (default is space).

Returns

out

[ndarray] Output array of StringDType, bytes_ or str_ dtype, depending on input types

See also:

`str.ljust`

Notes

While it is possible for *a* and *fillchar* to have different dtypes, passing a non-ASCII character in *fillchar* when *a* is of dtype “S” is not allowed, and a `ValueError` is raised.

Examples

```
>>> import numpy as np
>>> c = np.array(['aAaAaA', ' aA ', 'abBABba'])
>>> np.strings.ljust(c, width=3)
array(['aAaAaA', ' aA ', 'abBABba'], dtype='<U7')
>>> np.strings.ljust(c, width=9)
array(['aAaAaA ', ' aA   ', 'abBABba  '], dtype='<U9')
```

`strings.lower(a)`

Return an array with the elements converted to lowercase.

Call `str.lower` element-wise.

For 8-bit strings, this method is locale-dependent.

Parameters

a

[array-like, with StringDType, bytes_, or str_ dtype] Input array.

Returns**out**

[ndarray] Output array of StringDType, bytes_ or str_ dtype, depending on input types

See also:`str.lower`**Examples**

```
>>> import numpy as np
>>> c = np.array(['A1B C', '1BCA', 'BCA1']); c
array(['A1B C', '1BCA', 'BCA1'], dtype='<U5')
>>> np.strings.lower(c)
array(['a1b c', '1bca', 'bca1'], dtype='<U5')
```

`strings.lstrip(a, chars=None)`For each element in *a*, return a copy with the leading characters removed.**Parameters****a**

[array-like, with StringDType, bytes_, or str_ dtype]

chars[scalar with the same dtype as a, optional] The *chars* argument is a string specifying the set of characters to be removed. If *None*, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped.**Returns****out**

[ndarray] Output array of StringDType, bytes_ or str_ dtype, depending on input types

See also:`str.lstrip`**Examples**

```
>>> import numpy as np
>>> c = np.array(['aAaAa', ' aA ', 'abBABba'])
>>> c
array(['aAaAa', ' aA ', 'abBABba'], dtype='<U7')
# The 'a' variable is unstripped from c[1] because of leading whitespace.
>>> np.strings.lstrip(c, 'a')
array(['aAaAa', ' aA ', 'bBABba'], dtype='<U7')
>>> np.strings.lstrip(c, 'A') # leaves c unchanged
array(['aAaAa', ' aA ', 'abBABba'], dtype='<U7')
>>> (np.strings.lstrip(c, ' ') == np.strings.lstrip(c, '')).all()
np.False_
>>> (np.strings.lstrip(c, ' ') == np.strings.lstrip(c)).all()
np.True_
```

`strings.mod(a, values)`

Return $(a \% i)$, that is pre-Python 2.6 string formatting (interpolation), element-wise for a pair of array_likes of str or unicode.

Parameters

a

[array_like, with bytes_ or str_ dtype]

values

[array_like of values] These values will be element-wise interpolated into the string.

Returns

out

[ndarray] Output array of StringDType, bytes_ or str_ dtype, depending on input types

Examples

```
>>> import numpy as np
>>> a = np.array(["NumPy is a %s library"])
>>> np.strings.mod(a, values=["Python"])
array(['NumPy is a Python library'], dtype='<U25')
```

```
>>> a = np.array([b'%d bytes', b'%d bits'])
>>> values = np.array([8, 64])
>>> np.strings.mod(a, values)
array([b'8 bytes', b'64 bits'], dtype='|S7')
```

`strings.multiply(a, i)`

Return $(a * i)$, that is string multiple concatenation, element-wise.

Values in *i* of less than 0 are treated as 0 (which yields an empty string).

Parameters

a

[array_like, with StringDType, bytes_ or str_ dtype]

i

[array_like, with any integer dtype]

Returns

out

[ndarray] Output array of StringDType, bytes_ or str_ dtype, depending on input types

Examples

```
>>> import numpy as np
>>> a = np.array(["a", "b", "c"])
>>> np.strings.multiply(a, 3)
array(['aaa', 'bbb', 'ccc'], dtype='<U3')
>>> i = np.array([1, 2, 3])
>>> np.strings.multiply(a, i)
array(['a', 'bb', 'ccc'], dtype='<U3')
>>> np.strings.multiply(np.array(['a']), i)
array(['a', 'aa', 'aaa'], dtype='<U3')
>>> a = np.array(['a', 'b', 'c', 'd', 'e', 'f']).reshape((2, 3))
>>> np.strings.multiply(a, 3)
array([[ 'aaa', 'bbb', 'ccc'],
       ['ddd', 'eee', 'fff']], dtype='<U3')
>>> np.strings.multiply(a, i)
array([[ 'a', 'bb', 'ccc'],
       ['d', 'ee', 'fff']], dtype='<U3')
```

`strings.partition(a, sep)`

Partition each element in `a` around `sep`.

For each element in `a`, split the element at the first occurrence of `sep`, and return a 3-tuple containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, the first item of the tuple will contain the whole string, and the second and third ones will be the empty string.

Parameters

a

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array

sep

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Separator to split each string element in `a`.

Returns

out

[3-tuple:]

- array with `StringDType`, `bytes_` or `str_ dtype` with the part before the separator
- array with `StringDType`, `bytes_` or `str_ dtype` with the separator
- array with `StringDType`, `bytes_` or `str_ dtype` with the part after the separator

See also:

`str.partition`

Examples

```
>>> import numpy as np
>>> x = np.array(["Numpy is nice!"])
>>> np.strings.partition(x, " ")
(array(['Numpy'], dtype='<U5'),
 array([''], dtype='<U1'),
 array(['is nice!'], dtype='<U8'))
```

`strings.replace(a, old, new, count=-1)`

For each element in *a*, return a copy of the string with occurrences of substring *old* replaced by *new*.

Parameters

a

[array_like, with bytes_ or str_ dtype]

old, new

[array_like, with bytes_ or str_ dtype]

count

[array_like, with int_ dtype] If the optional argument *count* is given, only the first *count* occurrences are replaced.

Returns

out

[ndarray] Output array of StringDType, bytes_ or str_ dtype, depending on input types

See also:

[`str.replace`](#)

Examples

```
>>> import numpy as np
>>> a = np.array(["That is a mango", "Monkeys eat mangos"])
>>> np.strings.replace(a, 'mango', 'banana')
array(['That is a banana', 'Monkeys eat bananas'], dtype='<U19')
```

```
>>> a = np.array(["The dish is fresh", "This is it"])
>>> np.strings.replace(a, 'is', 'was')
array(['The dwash was fresh', 'Thwas was it'], dtype='<U19')
```

`strings.rjust(a, width, fillchar='')`

Return an array with the elements of *a* right-justified in a string of length *width*.

Parameters

a

[array-like, with StringDType, bytes_, or str_ dtype]

width

[array_like, with any integer dtype] The length of the resulting strings, unless *width* < `str_len(a)`.

fillchar

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Optional padding character to use (default is space).

Returns**out**

[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.rjust`

Notes

While it is possible for `a` and `fillchar` to have different dtypes, passing a non-ASCII character in `fillchar` when `a` is of dtype “S” is not allowed, and a `ValueError` is raised.

Examples

```
>>> import numpy as np
>>> a = np.array(['aAaAaA', '  aA  ', 'abBABba'])
>>> np.strings.rjust(a, width=3)
array(['aAaAaA', '  aA  ', 'abBABba'], dtype='<U7')
>>> np.strings.rjust(a, width=9)
array(['  aAaAaA', '      aA  ', '  abBABba'], dtype='<U9')
```

`strings.rpartition(a, sep)`

Partition (split) each element around the right-most separator.

For each element in `a`, split the element at the last occurrence of `sep`, and return a 3-tuple containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, the third item of the tuple will contain the whole string, and the first and second ones will be the empty string.

Parameters**a**

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array

sep

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Separator to split each string element in `a`.

Returns**out**

[3-tuple:]

- array with `StringDType`, `bytes_` or `str_ dtype` with the part before the separator
- array with `StringDType`, `bytes_` or `str_ dtype` with the separator
- array with `StringDType`, `bytes_` or `str_ dtype` with the part after the separator

See also:

`str.rpartition`

Examples

```
>>> import numpy as np
>>> a = np.array(['aAaAaA', ' aA ', 'abBABba'])
>>> np.strings.rpartition(a, 'A')
(array(['aAaAaA', ' a', 'abB'], dtype='<U5'),
 array(['A', 'A', 'A'], dtype='<U1'),
 array(['', ' ', 'Bba'], dtype='<U3'))
```

`strings.rstrip(a, chars=None)`

For each element in *a*, return a copy with the trailing characters removed.

Parameters

a

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

chars

[scalar with the same dtype as *a*, optional] The `chars` argument is a string specifying the set of characters to be removed. If `None`, the `chars` argument defaults to removing whitespace. The `chars` argument is not a prefix or suffix; rather, all combinations of its values are stripped.

Returns

out

[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.rstrip`

Examples

```
>>> import numpy as np
>>> c = np.array(['aAaAaA', 'abBABba'])
>>> c
array(['aAaAaA', 'abBABba'], dtype='<U7')
>>> np.strings.rstrip(c, 'a')
array(['aAaAaA', 'abBABb'], dtype='<U7')
>>> np.strings.rstrip(c, 'A')
array(['aAaAa', 'abBABba'], dtype='<U7')
```

`strings.slice(a, start=None, stop=<no value>, step=None, /)`

Slice the strings in *a* by slices specified by *start*, *stop*, *step*. Like in the regular Python `slice` object, if only *start* is specified then it is interpreted as the *stop*.

Parameters

a

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array

start

[None, an integer or an array of integers] The start of the slice, broadcasted to *a*'s shape

stop

[None, an integer or an array of integers] The end of the slice, broadcasted to *a*'s shape

step

[None, an integer or an array of integers] The step for the slice, broadcasted to *a*'s shape

Returns**out**

[ndarray] Output array of `StringDType`, `bytes_` or `str_` dtype, depending on input type

Examples

```
>>> import numpy as np
>>> a = np.array(['hello', 'world'])
>>> np.strings.slice(a, 2)
array(['he', 'wo'], dtype='<U5')
```

```
>>> np.strings.slice(a, 2, None)
array(['llo', 'rld'], dtype='<U5')
```

```
>>> np.strings.slice(a, 1, 5, 2)
array(['el', 'ol'], dtype='<U5')
```

One can specify different start/stop/step for different array entries:

```
>>> np.strings.slice(a, np.array([1, 2]), np.array([4, 5]))
array(['ell', 'rld'], dtype='<U5')
```

Negative slices have the same meaning as in regular Python:

```
>>> b = np.array(['hello world', 'γεια σου κόσμε', '????', ' ? '],
...               dtype=np.dtypes.StringDType())
>>> np.strings.slice(b, -2)
array(['hello wor', 'γεια σου κόσ', '??', '?'], dtype=StringDType())
```

```
>>> np.strings.slice(b, -2, None)
array(['ld', 'με', '??', '?'], dtype=StringDType())
```

```
>>> np.strings.slice(b, [3, -10, 2, -3], [-1, -2, -1, 3])
array(['lo worl', ' σου κόσ', '?', '? ?'], dtype=StringDType())
```

```
>>> np.strings.slice(b, None, None, -1)
array(['dlrow olleh', 'ερσόκ υοο αλεγ', '????', '? ?'],
      dtype=StringDType())
```

`strings.strip(a, chars=None)`

For each element in *a*, return a copy with the leading and trailing characters removed.

Parameters**a**

[array-like, with `StringDType`, `bytes_`, or `str_` dtype]

chars

[scalar with the same dtype as *a*, optional] The *chars* argument is a string specifying the set of characters to be removed. If *None*, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped.

Returns**out**

[ndarray] Output array of StringDType, bytes_ or str_ dtype, depending on input types

See also:`str.strip`**Examples**

```
>>> import numpy as np
>>> c = np.array(['aAaAaA', '  aA  ', 'abBABba'])
>>> c
array(['aAaAaA', '  aA  ', 'abBABba'], dtype='<U7')
>>> np.strings.strip(c)
array(['aAaAaA', 'aA', 'abBABba'], dtype='<U7')
# 'a' unstripped from c[1] because of leading whitespace.
>>> np.strings.strip(c, 'a')
array(['AaAaA', '  aA  ', 'bBABb'], dtype='<U7')
# 'A' unstripped from c[1] because of trailing whitespace.
>>> np.strings.strip(c, 'A')
array(['aAaAa', '  aA  ', 'abBABba'], dtype='<U7')
```

`strings.swapcase(a)`

Return element-wise a copy of the string with uppercase characters converted to lowercase and vice versa.

Calls `str.swapcase` element-wise.

For 8-bit strings, this method is locale-dependent.

Parameters**a**

[array-like, with StringDType, bytes_, or str_ dtype] Input array.

Returns**out**

[ndarray] Output array of StringDType, bytes_ or str_ dtype, depending on input types

See also:`str.swapcase`**Examples**

```
>>> import numpy as np
>>> c=np.array(['a1B c', '1b Ca', 'b Ca1', 'cA1b'], 'S5'); c
array(['a1B c', '1b Ca', 'b Ca1', 'cA1b'],
      dtype='|S5')
>>> np.strings.swapcase(c)
array(['A1b C', '1B cA', 'B cA1', 'Ca1B'],
      dtype='|S5')
```

`strings.title(a)`

Return element-wise title cased version of string or unicode.

Title case words start with uppercase characters, all remaining cased characters are lowercase.

Calls `str.title` element-wise.

For 8-bit strings, this method is locale-dependent.

Parameters

a

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array.

Returns

out

[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.title`

Examples

```
>>> import numpy as np
>>> c=np.array(['a1b c', '1b ca', 'b ca1', 'ca1b'], 'S5'); c
array(['a1b c', '1b ca', 'b ca1', 'ca1b'],
      dtype='<S5')
>>> np.strings.title(c)
array(['A1B C', '1B Ca', 'B Ca1', 'Ca1B'],
      dtype='<S5')
```

`strings.translate(a, table, deletechars=None)`

For each element in *a*, return a copy of the string where all characters occurring in the optional argument *deletechars* are removed, and the remaining characters have been mapped through the given translation table.

Calls `str.translate` element-wise.

Parameters

a

[array-like, with `bytes_` or `str_ dtype`]

table

[str of length 256]

deletechars

[str]

Returns

out

[ndarray] Output array of `str` or `unicode`, depending on input type

See also:

`str.translate`

Examples

```
>>> import numpy as np
>>> a = np.array(['a1b c', '1bca', 'bca1'])
>>> table = a[0].maketrans('abc', '123')
>>> deletechars = ' '
>>> np.char.translate(a, table, deletechars)
array(['112 3', '1231', '2311'], dtype='<U5')
```

`strings.upper(a)`

Return an array with the elements converted to uppercase.

Calls `str.upper` element-wise.

For 8-bit strings, this method is locale-dependent.

Parameters

a
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array.

Returns

out
[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.upper`

Examples

```
>>> import numpy as np
>>> c = np.array(['a1b c', '1bca', 'bca1']); c
array(['a1b c', '1bca', 'bca1'], dtype='<U5')
>>> np.strings.upper(c)
array(['A1B C', '1BCA', 'BCA1'], dtype='<U5')
```

`strings.zfill(a, width)`

Return the numeric string left-filled with zeros. A leading sign prefix (+/-) is handled by inserting the padding after the sign character rather than before.

Parameters

a
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

width
[array_like, with any integer dtype] Width of string to left-fill elements in *a*.

Returns

out
[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input type

See also:

`str.zfill`

Examples

```
>>> import numpy as np
>>> np.strings.zfill(['1', '-1', '+1'], 3)
array(['001', '-01', '+01'], dtype='<U3')
```

Comparison

The `numpy.strings` module also exports the comparison universal functions that can now operate on string arrays as well.

<code>equal(x1, x2, /[, out, where, casting, ...])</code>	Return $(x1 == x2)$ element-wise.
<code>not_equal(x1, x2, /[, out, where, casting, ...])</code>	Return $(x1 != x2)$ element-wise.
<code>greater_equal(x1, x2, /[, out, where, ...])</code>	Return the truth value of $(x1 \geq x2)$ element-wise.
<code>less_equal(x1, x2, /[, out, where, casting, ...])</code>	Return the truth value of $(x1 \leq x2)$ element-wise.
<code>greater(x1, x2, /[, out, where, casting, ...])</code>	Return the truth value of $(x1 > x2)$ element-wise.
<code>less(x1, x2, /[, out, where, casting, ...])</code>	Return the truth value of $(x1 < x2)$ element-wise.

```
strings.equal(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'equal'>
```

Return $(x1 == x2)$ element-wise.

Parameters

x1, x2

[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Output array, element-wise comparison of `x1` and `x2`. Typically of type `bool`, unless `dtype=np.object_` is passed. This is a scalar if both `x1` and `x2` are scalars.

See also:

[`not\_equal`](#), [`greater\_equal`](#), [`less\_equal`](#), [`greater`](#), [`less`](#)

Examples

```
>>> import numpy as np
>>> np.equal([0, 1, 3], np.arange(3))
array([ True,  True, False])
```

What is compared are values, not types. So an int (1) and an array of length one can evaluate as True:

```
>>> np.equal(1, np.ones(1))
array([ True])
```

The `==` operator can be used as a shorthand for `np.equal` on ndarrays.

```
>>> a = np.array([2, 4, 6])
>>> b = np.array([2, 4, 2])
>>> a == b
array([ True,  True, False])
```

```
strings.not_equal(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None,
                  subok=True[, signature]) = <ufunc 'not_equal'>
```

Return $(x1 \neq x2)$ element-wise.

Parameters

x1, x2

[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Output array, element-wise comparison of `x1` and `x2`. Typically of type bool, unless `dtype=np.object_` is passed. This is a scalar if both `x1` and `x2` are scalars.

See also:

[*equal*](#), [*greater*](#), [*greater_equal*](#), [*less*](#), [*less_equal*](#)

Examples

```
>>> import numpy as np
>>> np.not_equal([1., 2.], [1., 3.])
array([False,  True])
>>> np.not_equal([1, 2], [[1, 3], [1, 4]])
array([[False,  True],
       [False,  True]])
```

The `!=` operator can be used as a shorthand for `np.not_equal` on ndarrays.

```
>>> a = np.array([1., 2.])
>>> b = np.array([1., 3.])
>>> a != b
array([False,  True])
```

`strings.greater_equal(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'greater_equal'>`

Return the truth value of $(x1 \geq x2)$ element-wise.

Parameters

x1, x2

[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[bool or ndarray of bool] Output array, element-wise comparison of `x1` and `x2`. Typically of type bool, unless `dtype=np.object_` is passed. This is a scalar if both `x1` and `x2` are scalars.

See also:

[`greater`](#), [`less`](#), [`less\_equal`](#), [`equal`](#), [`not\_equal`](#)

Examples

```
>>> import numpy as np
>>> np.greater_equal([4, 2, 1], [2, 2, 2])
array([ True,  True, False])
```

The `>=` operator can be used as a shorthand for `np.greater_equal` on ndarrays.

```
>>> a = np.array([4, 2, 1])
>>> b = np.array([2, 2, 2])
>>> a >= b
array([ True,  True, False])
```

```
strings.less_equal(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None,
                    subok=True[, signature]) = <ufunc 'less_equal'>
```

Return the truth value of $(x1 \leq x2)$ element-wise.

Parameters

x1, x2

[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Output array, element-wise comparison of `x1` and `x2`. Typically of type bool, unless `dtype=np.object_` is passed. This is a scalar if both `x1` and `x2` are scalars.

See also:

[*greater*](#), [*less*](#), [*greater_equal*](#), [*equal*](#), [*not_equal*](#)

Examples

```
>>> import numpy as np
>>> np.less_equal([4, 2, 1], [2, 2, 2])
array([False,  True,  True])
```

The `<=` operator can be used as a shorthand for `np.less_equal` on ndarrays.

```
>>> a = np.array([4, 2, 1])
>>> b = np.array([2, 2, 2])
>>> a <= b
array([False,  True,  True])
```

`strings.greater(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'greater'>`

Return the truth value of $(x1 > x2)$ element-wise.

Parameters

x1, x2

[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Output array, element-wise comparison of `x1` and `x2`. Typically of type bool, unless `dtype=np.object_` is passed. This is a scalar if both `x1` and `x2` are scalars.

See also:

[greater_equal](#), [less](#), [less_equal](#), [equal](#), [not_equal](#)

Examples

```
>>> import numpy as np
>>> np.greater([4,2],[2,2])
array([ True, False])
```

The `>` operator can be used as a shorthand for `np.greater` on ndarrays.

```
>>> a = np.array([4, 2])
>>> b = np.array([2, 2])
>>> a > b
array([ True, False])
```

`strings.less(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'less'>`

Return the truth value of $(x1 < x2)$ element-wise.

Parameters

x1, x2

[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Output array, element-wise comparison of *x1* and *x2*. Typically of type bool, unless `dtype=np.object_` is passed. This is a scalar if both *x1* and *x2* are scalars.

See also:

[*greater*](#), [*less_equal*](#), [*greater_equal*](#), [*equal*](#), [*not_equal*](#)

Examples

```
>>> import numpy as np
>>> np.less([1, 2], [2, 2])
array([ True, False])
```

The `<` operator can be used as a shorthand for `np.less` on ndarrays.

```
>>> a = np.array([1, 2])
>>> b = np.array([2, 2])
>>> a < b
array([ True, False])
```

String information

<code>count(a, sub[, start, end])</code>	Returns an array with the number of non-overlapping occurrences of substring <code>sub</code> in the range <code>[start, end)</code> .
<code>endswith(a, suffix[, start, end])</code>	Returns a boolean array which is <i>True</i> where the string element in <code>a</code> ends with <code>suffix</code> , otherwise <i>False</i> .
<code>find(a, sub[, start, end])</code>	For each element, return the lowest index in the string where substring <code>sub</code> is found, such that <code>sub</code> is contained in the range <code>[start, end)</code> .
<code>index(a, sub[, start, end])</code>	Like <code>find</code> , but raises <code>ValueError</code> when the substring is not found.
<code>isalnum(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if all characters in the string are alphanumeric and there is at least one character, false otherwise.
<code>isalpha(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if all characters in the data interpreted as a string are alphabetic and there is at least one character, false otherwise.
<code>isdecimal(x, /[, out, where, casting, ...])</code>	For each element, return <i>True</i> if there are only decimal characters in the element.
<code>isdigit(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if all characters in the string are digits and there is at least one character, false otherwise.
<code>islower(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if all cased characters in the string are lowercase and there is at least one cased character, false otherwise.
<code>isnumeric(x, /[, out, where, casting, ...])</code>	For each element, return <i>True</i> if there are only numeric characters in the element.
<code>isspace(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if there are only whitespace characters in the string and there is at least one character, false otherwise.
<code>istitle(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if the element is a titlecased string and there is at least one character, false otherwise.
<code>isupper(x, /[, out, where, casting, order, ...])</code>	Return true for each element if all cased characters in the string are uppercase and there is at least one character, false otherwise.
<code>rfind(a, sub[, start, end])</code>	For each element, return the highest index in the string where substring <code>sub</code> is found, such that <code>sub</code> is contained in the range <code>[start, end)</code> .
<code>rindex(a, sub[, start, end])</code>	Like <code>rfind</code> , but raises <code>ValueError</code> when the substring <code>sub</code> is not found.
<code>startswith(a, prefix[, start, end])</code>	Returns a boolean array which is <i>True</i> where the string element in <code>a</code> starts with <code>prefix</code> , otherwise <i>False</i> .
<code>str_len(x, /[, out, where, casting, order, ...])</code>	Returns the length of each element.

`strings.count(a, sub, start=0, end=None)`

Returns an array with the number of non-overlapping occurrences of substring `sub` in the range `[start, end)`.

Parameters**a**[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]**sub**[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] The substring to search for.

start, end

[array_like, with any integer dtype] The range to look in, interpreted as in slice notation.

Returns**y**

[ndarray] Output array of ints

See also:`str.count`**Examples**

```

>>> import numpy as np
>>> c = np.array(['aAaAaA', '  aA  ', 'abBABba'])
>>> c
array(['aAaAaA', '  aA  ', 'abBABba'], dtype='<U7')
>>> np.strings.count(c, 'A')
array([3, 1, 1])
>>> np.strings.count(c, 'aA')
array([3, 1, 0])
>>> np.strings.count(c, 'A', start=1, end=4)
array([2, 1, 1])
>>> np.strings.count(c, 'A', start=1, end=3)
array([1, 0, 0])

```

`strings.endswith(a, suffix, start=0, end=None)`Returns a boolean array which is *True* where the string element in *a* ends with *suffix*, otherwise *False*.**Parameters****a**

[array-like, with StringDType, bytes_, or str_ dtype]

suffix

[array-like, with StringDType, bytes_, or str_ dtype]

start, end[array_like, with any integer dtype] With *start*, test beginning at that position. With *end*, stop comparing at that position.**Returns****out**

[ndarray] Output array of bools

See also:`str.endswith`

Examples

```
>>> import numpy as np
>>> s = np.array(['foo', 'bar'])
>>> s
array(['foo', 'bar'], dtype='<U3')
>>> np.strings.endswith(s, 'ar')
array([False,  True])
>>> np.strings.endswith(s, 'a', start=1, end=2)
array([False,  True])
```

`strings.find(a, sub, start=0, end=None)`

For each element, return the lowest index in the string where substring `sub` is found, such that `sub` is contained in the range `[start, end)`.

Parameters

- a**
[array_like, with StringDType, bytes_ or str_ dtype]
- sub**
[array_like, with bytes_ or str_ dtype] The substring to search for.
- start, end**
[array_like, with any integer dtype] The range to look in, interpreted as in slice notation.

Returns

- y**
[ndarray] Output array of ints

See also:

`str.find`

Examples

```
>>> import numpy as np
>>> a = np.array(["NumPy is a Python library"])
>>> np.strings.find(a, "Python")
array([11])
```

`strings.index(a, sub, start=0, end=None)`

Like `find`, but raises `ValueError` when the substring is not found.

Parameters

- a**
[array-like, with StringDType, bytes_, or str_ dtype]
- sub**
[array-like, with StringDType, bytes_, or str_ dtype]
- start, end**
[array_like, with any integer dtype, optional]

Returns

- out**
[ndarray] Output array of ints.

See also:

[`find`](#), [`str.index`](#)

Examples

```
>>> import numpy as np
>>> a = np.array(["Computer Science"])
>>> np.strings.index(a, "Science", start=0, end=None)
array([9])
```

```
strings.isalnum(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,
signature]) = <ufunc 'isalnum'>
```

Returns true for each element if all characters in the string are alphanumeric and there is at least one character, false otherwise.

Parameters

x

[array_like, with StringDType, bytes_ or str_ dtype]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray] Output array of bool This is a scalar if *x* is a scalar.

See also:

[`str.isalnum`](#)

Examples

```
>>> import numpy as np
>>> a = np.array(['a', '1', 'a1', '(', ''])
>>> np.strings.isalnum(a)
array([ True,  True,  True, False, False])
```

```
strings.isalpha(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,
signature]) = <ufunc 'isalpha'>
```

Returns true for each element if all characters in the data interpreted as a string are alphabetic and there is at least one character, false otherwise.

For byte strings (i.e. `bytes`), alphabetic characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'`. For Unicode strings, alphabetic characters are those characters defined in the Unicode character database as “Letter”.

Parameters

x

[array_like, with `StringDType`, `bytes_`, or `str_ dtype`]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

y

[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.isalpha`

Examples

```
>>> import numpy as np
>>> a = np.array(['a', 'b', '0'])
>>> np.strings.isalpha(a)
array([ True,  True, False])
```

```
>>> a = np.array(['a', 'b', '0'], ['c', '1', '2'])
>>> np.strings.isalpha(a)
array([ True,  True, False], [ True, False, False])
```

`strings.isdecimal(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'isdecimal'>`

For each element, return True if there are only decimal characters in the element.

Decimal characters include digit characters, and all characters that can be used to form decimal-radix numbers, e.g. `U+0660`, `ARABIC-INDIC DIGIT ZERO`.

Parameters

x

[array_like, with `StringDType` or `str_ dtype`]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None,

a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.isdecimal`

Examples

```
>>> import numpy as np
>>> np.strings.isdecimal(['12345', '4.99', '123ABC', ''])
array([ True, False, False, False])
```

`strings.isdigit(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'isdigit'>`

Returns true for each element if all characters in the string are digits and there is at least one character, false otherwise.

For byte strings, digits are the byte values in the sequence `b'0123456789'`. For Unicode strings, digits include decimal characters and digits that need special handling, such as the compatibility superscript digits. This also covers digits which cannot be used to form numbers in base 10, like the Kharosthi numbers.

Parameters

x

[array_like, with `StringDType`, `bytes_`, or `str_ dtype`]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y
[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.isdigit`

Examples

```
>>> import numpy as np
>>> a = np.array(['a', 'b', '0'])
>>> np.strings.isdigit(a)
array([False, False,  True])
>>> a = np.array(['a', 'b', '0'], ['c', '1', '2'])
>>> np.strings.isdigit(a)
array([[False, False,  True], [False,  True,  True]])
```

`strings.islower(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'islower'>`

Returns true for each element if all cased characters in the string are lowercase and there is at least one cased character, false otherwise.

Parameters

x
[array_like, with StringDType, bytes_ or str_ dtype]

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where
[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**
For other keyword-only arguments, see the [ufunc docs](#).

Returns

out
[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.islower`

Examples

```
>>> import numpy as np
>>> np.strings.islower("GHC")
array(False)
>>> np.strings.islower("ghc")
array(True)
```

```
strings.isnumeric(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'isnumeric'>
```

For each element, return True if there are only numeric characters in the element.

Numeric characters include digit characters, and all characters that have the Unicode numeric value property, e.g. U+2155, VULGAR FRACTION ONE FIFTH.

Parameters

x

[array_like, with StringDType or str_ dtype]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

[str.isnumeric](#)

Examples

```
>>> import numpy as np
>>> np.strings.isnumeric(['123', '123abc', '9.0', '1/4', 'VIII'])
array([ True, False, False, False, False])
```

```
strings.isspace(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'isspace'>
```

Returns true for each element if there are only whitespace characters in the string and there is at least one character, false otherwise.

For byte strings, whitespace characters are the ones in the sequence `b' \t\r\n\b\f'`. For Unicode strings, a character is whitespace, if, in the Unicode character database, its general category is Zs (“Separator, space”), or its bidirectional class is one of WS, B, or S.

Parameters**x**[array_like, with `StringDType`, `bytes_`, or `str_ dtype`]**out**

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**For other keyword-only arguments, see the [ufunc docs](#).**Returns****y**[ndarray] Output array of bools This is a scalar if *x* is a scalar.**See also:**[str.isspace](#)**Examples**

```
>>> np.char.isspace(list("a b c"))
array([False,  True, False,  True, False])
>>> np.char.isspace(b'\x0a \x0b \x0c')
np.True_
>>> np.char.isspace(b'\x0a \x0b \x0c N')
np.False_
```

```
strings.istitle(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,
signature]) = <ufunc 'istitle'>
```

Returns true for each element if the element is a titlecased string and there is at least one character, false otherwise.

Parameters**x**[array_like, with `StringDType`, `bytes_` or `str_ dtype`]**out**

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.istitle`

Examples

```
>>> import numpy as np
>>> np.strings.istitle("Numpy Is Great")
array(True)
```

```
>>> np.strings.istitle("Numpy is great")
array(False)
```

`strings.isupper` (*x*, */*, *out=None*, ***, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True* [, *signature*]) = `<ufunc 'isupper'>`

Return true for each element if all cased characters in the string are uppercase and there is at least one character, false otherwise.

Parameters

x

[array_like, with StringDType, bytes_ or str_ dtype]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.isupper`

Examples

```
>>> import numpy as np
>>> np.strings.isupper("GHC")
array(True)
>>> a = np.array(["hello", "HELLO", "Hello"])
>>> np.strings.isupper(a)
array([False,  True, False])
```

`strings.rfind(a, sub, start=0, end=None)`

For each element, return the highest index in the string where substring `sub` is found, such that `sub` is contained in the range `[start, end)`.

Parameters

a

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

sub

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] The substring to search for.

start, end

[array-like, with any integer dtype] The range to look in, interpreted as in slice notation.

Returns

y

[ndarray] Output array of ints

See also:

`str.rfind`

Examples

```
>>> import numpy as np
>>> a = np.array(["Computer Science"])
>>> np.strings.rfind(a, "Science", start=0, end=None)
array([9])
>>> np.strings.rfind(a, "Science", start=0, end=8)
array([-1])
>>> b = np.array(["Computer Science", "Science"])
>>> np.strings.rfind(b, "Science", start=0, end=None)
array([9, 0])
```

`strings.rindex(a, sub, start=0, end=None)`

Like `rfind`, but raises `ValueError` when the substring `sub` is not found.

Parameters

a

[array-like, with `bytes_` or `str_ dtype`]

sub

[array-like, with `bytes_` or `str_ dtype`]

start, end

[array-like, with any integer dtype, optional]

Returns**out**

[ndarray] Output array of ints.

See also:`rfind`, `str.rindex`**Examples**

```
>>> a = np.array(["Computer Science"])
>>> np.strings.rindex(a, "Science", start=0, end=None)
array([9])
```

`strings.startswith(a, prefix, start=0, end=None)`

Returns a boolean array which is *True* where the string element in *a* starts with *prefix*, otherwise *False*.

Parameters**a**[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]**prefix**[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]**start, end**[array-like, with any integer dtype] With *start*, test beginning at that position. With *end*, stop comparing at that position.**Returns****out**

[ndarray] Output array of bools

See also:`str.startswith`**Examples**

```
>>> import numpy as np
>>> s = np.array(['foo', 'bar'])
>>> s
array(['foo', 'bar'], dtype='<U3')
>>> np.strings.startswith(s, 'fo')
array([True, False])
>>> np.strings.startswith(s, 'o', start=1, end=2)
array([True, False])
```

`strings.str_len(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'str_len'>`

Returns the length of each element. For byte strings, this is the number of bytes, while, for Unicode strings, it is the number of Unicode code points.

Parameters

x
[array_like, with StringDType, bytes_, or str_ dtype]

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where
[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**
For other keyword-only arguments, see the [ufunc docs](#).

Returns

y
[ndarray] Output array of ints This is a scalar if *x* is a scalar.

See also:

[len](#)

Examples

```
>>> import numpy as np
>>> a = np.array(['Grace Hopper Conference', 'Open Source Day'])
>>> np.strings.str_len(a)
array([23, 15])
>>> a = np.array(['P', 'o'])
>>> np.strings.str_len(a)
array([1, 1])
>>> a = np.array(['hello', 'world'], ['P', 'o'])
>>> np.strings.str_len(a)
array([[5, 5], [1, 1]])
```

Test support

Common test support for all numpy test scripts.

This single module should provide all the common functionality for numpy tests in a single location, so that test scripts can just import it and work right away. For background, see the [Testing guidelines](#)

Asserts

<code>assert_allclose(actual, desired[, rtol, ...])</code>	Raises an AssertionError if two objects are not equal up to desired tolerance.
<code>assert_array_almost_equal_nulp(x, y[, nulp])</code>	Compare two arrays relatively to their spacing.
<code>assert_array_max_ulp(a, b[, maxulp, dtype])</code>	Check that all items of arrays differ in at most N Units in the Last Place.
<code>assert_array_equal(actual, desired[, ...])</code>	Raises an AssertionError if two array_like objects are not equal.
<code>assert_array_less(x, y[, err_msg, verbose, ...])</code>	Raises an AssertionError if two array_like objects are not ordered by less than.
<code>assert_equal(actual, desired[, err_msg, ...])</code>	Raises an AssertionError if two objects are not equal.
<code>assert_raises(assert_raises)</code>	Fail unless an exception of class exception_class is thrown by callable when invoked with arguments args and keyword arguments kwargs.
<code>assert_raises_regex(exception_class, ...)</code>	Fail unless an exception of class exception_class and with message that matches expected_regexp is thrown by callable when invoked with arguments args and keyword arguments kwargs.
<code>assert_warns(warning_class, *args, **kwargs)</code>	Fail unless the given callable throws the specified warning.
<code>assert_no_warnings(*args, **kwargs)</code>	Fail if the given callable produces any warnings.
<code>assert_no_gc_cycles(*args, **kwargs)</code>	Fail if the given callable produces any reference cycles.
<code>assert_string_equal(actual, desired)</code>	Test if two strings are equal.

`testing.assert_allclose` (*actual, desired, rtol=1e-07, atol=0, equal_nan=True, err_msg="", verbose=True, *, strict=False*)

Raises an AssertionError if two objects are not equal up to desired tolerance.

Given two array_like objects, check that their shapes and all elements are equal (but see the Notes for the special handling of a scalar). An exception is raised if the shapes mismatch or any values conflict. In contrast to the standard usage in numpy, NaNs are compared like numbers, no assertion is raised if both objects have NaNs in the same positions.

The test is equivalent to `allclose(actual, desired, rtol, atol)`, except that it is stricter: it doesn't broadcast its operands, and has tighter default tolerance values. It compares the difference between *actual* and *desired* to `atol + rtol * abs(desired)`.

Parameters

actual

[array_like] Array obtained.

desired

[array_like] Array desired.

rtol

[float, optional] Relative tolerance.

atol

[float | np.timedelta64, optional] Absolute tolerance.

equal_nan

[bool, optional.] If True, NaNs will compare equal.

err_msg

[str, optional] The error message to be printed in case of failure.

verbose

[bool, optional] If True, the conflicting values are appended to the error message.

strict

[bool, optional] If True, raise an `AssertionError` when either the shape or the data type of the arguments does not match. The special handling of scalars mentioned in the Notes section is disabled.

New in version 2.0.0.

Raises**`AssertionError`**

If actual and desired are not equal up to specified precision.

See also:

[`assert\_array\_almost\_equal\_nulp`](#), [`assert\_array\_max\_ulp`](#)

Notes

When one of *actual* and *desired* is a scalar and the other is *array_like*, the function performs the comparison as if the scalar were broadcasted to the shape of the array. Note that empty arrays are therefore considered equal to scalars. This behaviour can be disabled by setting `strict==True`.

Examples

```
>>> x = [1e-5, 1e-3, 1e-1]
>>> y = np.arccos(np.cos(x))
>>> np.testing.assert_allclose(x, y, rtol=1e-5, atol=0)
```

As mentioned in the Notes section, `assert_allclose` has special handling for scalars. Here, the test checks that the value of `numpy.sin` is nearly zero at integer multiples of π .

```
>>> x = np.arange(3) * np.pi
>>> np.testing.assert_allclose(np.sin(x), 0, atol=1e-15)
```

Use *strict* to raise an `AssertionError` when comparing an array with one or more dimensions against a scalar.

```
>>> np.testing.assert_allclose(np.sin(x), 0, atol=1e-15, strict=True)
Traceback (most recent call last):
...
AssertionError:
Not equal to tolerance rtol=1e-07, atol=1e-15

(shapes (3,), () mismatch)
ACTUAL: array([ 0.000000e+00,  1.224647e-16, -2.449294e-16])
DESIRED: array(0)
```

The *strict* parameter also ensures that the array data types match:

```
>>> y = np.zeros(3, dtype=np.float32)
>>> np.testing.assert_allclose(np.sin(x), y, atol=1e-15, strict=True)
Traceback (most recent call last):
...
AssertionError:
```

(continues on next page)

(continued from previous page)

```

Not equal to tolerance rtol=1e-07, atol=1e-15

(dtypes float64, float32 mismatch)
ACTUAL: array([ 0.000000e+00,  1.224647e-16, -2.449294e-16])
DESIRED: array([0., 0., 0.], dtype=float32)

```

testing.**assert_array_almost_equal_nulp**(*x*, *y*, *nulp*=1)

Compare two arrays relatively to their spacing.

This is a relatively robust method to compare two arrays whose amplitude is variable.

Parameters

x, y

[array_like] Input arrays.

nulp

[int, optional] The maximum number of unit in the last place for tolerance (see Notes). Default is 1.

Returns

None

Raises

AssertionError

If the spacing between *x* and *y* for one or more elements is larger than *nulp*.

See also:

[*assert_array_max_ulp*](#)

Check that all items of arrays differ in at most N Units in the Last Place.

[*spacing*](#)

Return the distance between *x* and the nearest adjacent number.

Notes

An assertion is raised if the following condition is not met:

```
abs(x - y) <= nulp * spacing(maximum(abs(x), abs(y)))
```

Examples

```

>>> x = np.array([1., 1e-10, 1e-20])
>>> eps = np.finfo(x.dtype).eps
>>> np.testing.assert_array_almost_equal_nulp(x, x*eps/2 + x)

```

```

>>> np.testing.assert_array_almost_equal_nulp(x, x*eps + x)
Traceback (most recent call last):
...
AssertionError: Arrays are not equal to 1 ULP (max is 2)

```

`testing.assert_array_max_ulp(a, b, maxulp=1, dtype=None)`

Check that all items of arrays differ in at most N Units in the Last Place.

Parameters

a, b

[array_like] Input arrays to be compared.

maxulp

[int, optional] The maximum number of units in the last place that elements of *a* and *b* can differ. Default is 1.

dtype

[dtype, optional] Data-type to convert *a* and *b* to if given. Default is None.

Returns

ret

[ndarray] Array containing number of representable floating point numbers between items in *a* and *b*.

Raises

AssertionError

If one or more elements differ by more than *maxulp*.

See also:

[`assert\_array\_almost\_equal\_nulp`](#)

Compare two arrays relatively to their spacing.

Notes

For computing the ULP difference, this API does not differentiate between various representations of NAN (ULP difference between 0x7fc00000 and 0xffc00000 is zero).

Examples

```
>>> a = np.linspace(0., 1., 100)
>>> res = np.testing.assert_array_max_ulp(a, np.arcsin(np.sin(a)))
```

`testing.assert_array_equal(actual, desired, err_msg="", verbose=True, *, strict=False)`

Raises an AssertionError if two array_like objects are not equal.

Given two array_like objects, check that the shape is equal and all elements of these objects are equal (but see the Notes for the special handling of a scalar). An exception is raised at shape mismatch or conflicting values. In contrast to the standard usage in numpy, NaNs are compared like numbers, no assertion is raised if both objects have NaNs in the same positions.

The usual caution for verifying equality with floating point numbers is advised.

Note: When either *actual* or *desired* is already an instance of `numpy.ndarray` and *desired* is not a dict, the behavior of `assert_equal(actual, desired)` is identical to the behavior of this function. Otherwise, this function performs `np.asarray` on the inputs before comparison, whereas `assert_equal` defines special comparison rules for common Python types. For example, only `assert_equal` can be used to compare nested

Python lists. In new code, consider using only `assert_equal`, explicitly converting either *actual* or *desired* to arrays if the behavior of `assert_array_equal` is desired.

Parameters

actual

[array_like] The actual object to check.

desired

[array_like] The desired, expected object.

err_msg

[str, optional] The error message to be printed in case of failure.

verbose

[bool, optional] If True, the conflicting values are appended to the error message.

strict

[bool, optional] If True, raise an AssertionError when either the shape or the data type of the array_like objects does not match. The special handling for scalars mentioned in the Notes section is disabled.

New in version 1.24.0.

Raises

AssertionError

If actual and desired objects are not equal.

See also:

`assert_allclose`

Compare two array_like objects for equality with desired relative and/or absolute precision.

`assert_array_almost_equal_nulp`, `assert_array_max_ulp`, `assert_equal`

Notes

When one of *actual* and *desired* is a scalar and the other is array_like, the function checks that each element of the array_like is equal to the scalar. Note that empty arrays are therefore considered equal to scalars. This behaviour can be disabled by setting `strict==True`.

Examples

```
>>> import numpy as np
```

The first assert does not raise an exception:

```
>>> np.testing.assert_array_equal([1.0, 2.33333, np.nan],
...                               [np.exp(0), 2.33333, np.nan])
```

Assert fails with numerical imprecision with floats:

```
>>> np.testing.assert_array_equal([1.0,np.pi,np.nan],
...                               [1, np.sqrt(np.pi)**2, np.nan])
Traceback (most recent call last):
...
AssertionError:
Arrays are not equal

Mismatched elements: 1 / 3 (33.3%)
Mismatch at index:
[1]: 3.141592653589793 (ACTUAL), 3.1415926535897927 (DESIRED)
Max absolute difference among violations: 4.4408921e-16
Max relative difference among violations: 1.41357986e-16
ACTUAL: array([1.      , 3.141593,      nan])
DESIRED: array([1.      , 3.141593,      nan])
```

Use `assert_allclose` or one of the `nulp` (number of floating point values) functions for these cases instead:

```
>>> np.testing.assert_allclose([1.0,np.pi,np.nan],
...                             [1, np.sqrt(np.pi)**2, np.nan],
...                             rtol=1e-10, atol=0)
```

As mentioned in the Notes section, `assert_array_equal` has special handling for scalars. Here the test checks that each value in `x` is 3:

```
>>> x = np.full((2, 5), fill_value=3)
>>> np.testing.assert_array_equal(x, 3)
```

Use `strict` to raise an `AssertionError` when comparing a scalar with an array:

```
>>> np.testing.assert_array_equal(x, 3, strict=True)
Traceback (most recent call last):
...
AssertionError:
Arrays are not equal

(shapes (2, 5), () mismatch)
ACTUAL: array([[3, 3, 3, 3, 3],
               [3, 3, 3, 3, 3]])
DESIRED: array(3)
```

The `strict` parameter also ensures that the array data types match:

```
>>> x = np.array([2, 2, 2])
>>> y = np.array([2., 2., 2.], dtype=np.float32)
>>> np.testing.assert_array_equal(x, y, strict=True)
Traceback (most recent call last):
...
AssertionError:
Arrays are not equal

(dtypes int64, float32 mismatch)
ACTUAL: array([2, 2, 2])
DESIRED: array([2., 2., 2.], dtype=float32)
```

`testing.assert_array_less(x, y, err_msg="", verbose=True, *, strict=False)`

Raises an `AssertionError` if two array_like objects are not ordered by less than.

Given two array_like objects `x` and `y`, check that the shape is equal and all elements of `x` are strictly less than the

corresponding elements of y (but see the Notes for the special handling of a scalar). An exception is raised at shape mismatch or values that are not correctly ordered. In contrast to the standard usage in NumPy, no assertion is raised if both objects have NaNs in the same positions.

Parameters

x

[array_like] The smaller object to check.

y

[array_like] The larger object to compare.

err_msg

[string] The error message to be printed in case of failure.

verbose

[bool] If True, the conflicting values are appended to the error message.

strict

[bool, optional] If True, raise an AssertionError when either the shape or the data type of the array_like objects does not match. The special handling for scalars mentioned in the Notes section is disabled.

New in version 2.0.0.

Raises

AssertionError

If x is not strictly smaller than y , element-wise.

See also:

assert_array_equal

tests objects for equality

assert_array_almost_equal

test objects for equality up to precision

Notes

When one of x and y is a scalar and the other is array_like, the function performs the comparison as though the scalar were broadcasted to the shape of the array. This behaviour can be disabled with the *strict* parameter.

Examples

The following assertion passes because each finite element of x is strictly less than the corresponding element of y , and the NaNs are in corresponding locations.

```
>>> x = [1.0, 1.0, np.nan]
>>> y = [1.1, 2.0, np.nan]
>>> np.testing.assert_array_less(x, y)
```

The following assertion fails because the zeroth element of x is no longer strictly less than the zeroth element of y .

```
>>> y[0] = 1
>>> np.testing.assert_array_less(x, y)
Traceback (most recent call last):
...
```

(continues on next page)

(continued from previous page)

```

AssertionError:
Arrays are not strictly ordered `x < y`

Mismatched elements: 1 / 3 (33.3%)
Mismatch at index:
  [0]: 1.0 (x), 1.0 (y)
Max absolute difference among violations: 0.
Max relative difference among violations: 0.
  x: array([ 1.,  1., nan])
  y: array([ 1.,  2., nan])

```

Here, y is a scalar, so each element of x is compared to y , and the assertion passes.

```

>>> x = [1.0, 4.0]
>>> y = 5.0
>>> np.testing.assert_array_less(x, y)

```

However, with `strict=True`, the assertion will fail because the shapes do not match.

```

>>> np.testing.assert_array_less(x, y, strict=True)
Traceback (most recent call last):
...
AssertionError:
Arrays are not strictly ordered `x < y`

(shapes (2,), () mismatch)
  x: array([1., 4.])
  y: array(5.)

```

With `strict=True`, the assertion also fails if the dtypes of the two arrays do not match.

```

>>> y = [5, 5]
>>> np.testing.assert_array_less(x, y, strict=True)
Traceback (most recent call last):
...
AssertionError:
Arrays are not strictly ordered `x < y`

(dtypes float64, int64 mismatch)
  x: array([1., 4.])
  y: array([5, 5])

```

`testing.assert_equal` (*actual, desired, err_msg="", verbose=True, *, strict=False*)

Raises an `AssertionError` if two objects are not equal.

Given two objects (scalars, lists, tuples, dictionaries or numpy arrays), check that all elements of these objects are equal. An exception is raised at the first conflicting values.

This function handles NaN comparisons as if NaN was a “normal” number. That is, `AssertionError` is not raised if both objects have NaNs in the same positions. This is in contrast to the IEEE standard on NaNs, which says that NaN compared to anything must return False.

Parameters

actual

[array_like] The object to check.

desired

[array_like] The expected object.

err_msg

[str, optional] The error message to be printed in case of failure.

verbose

[bool, optional] If True, the conflicting values are appended to the error message.

strict

[bool, optional] If True and either of the *actual* and *desired* arguments is an array, raise an `AssertionError` when either the shape or the data type of the arguments does not match. If neither argument is an array, this parameter has no effect.

New in version 2.0.0.

Raises**AssertionError**

If *actual* and *desired* are not equal.

See also:

`assert_allclose`
`assert_array_almost_equal_nulp`
`assert_array_max_ulp`

Notes

When one of *actual* and *desired* is a scalar and the other is *array_like*, the function checks that each element of the *array_like* is equal to the scalar. Note that empty arrays are therefore considered equal to scalars. This behaviour can be disabled by setting `strict==True`.

Examples

```
>>> np.testing.assert_equal([4, 5], [4, 6])
Traceback (most recent call last):
...
AssertionError:
Items are not equal:
item=1
  ACTUAL: 5
  DESIRED: 6
```

The following comparison does not raise an exception. There are NaNs in the inputs, but they are in the same positions.

```
>>> np.testing.assert_equal(np.array([1.0, 2.0, np.nan]), [1, 2, np.nan])
```

As mentioned in the Notes section, `assert_equal` has special handling for scalars when one of the arguments is an array. Here, the test checks that each value in *x* is 3:

```
>>> x = np.full((2, 5), fill_value=3)
>>> np.testing.assert_equal(x, 3)
```

Use *strict* to raise an `AssertionError` when comparing a scalar with an array of a different shape:

```
>>> np.testing.assert_equal(x, 3, strict=True)
Traceback (most recent call last):
...
AssertionError:
Arrays are not equal

(shapes (2, 5), () mismatch)
ACTUAL: array([[3, 3, 3, 3, 3],
              [3, 3, 3, 3, 3]])
DESIRED: array(3)
```

The *strict* parameter also ensures that the array data types match:

```
>>> x = np.array([2, 2, 2])
>>> y = np.array([2., 2., 2.], dtype=np.float32)
>>> np.testing.assert_equal(x, y, strict=True)
Traceback (most recent call last):
...
AssertionError:
Arrays are not equal

(dtypes int64, float32 mismatch)
ACTUAL: array([2, 2, 2])
DESIRED: array([2., 2., 2.], dtype=float32)
```

`testing.assert_raises(exception_class, callable, *args, **kwargs)` *assert_raises(exception_class)*

`testing.assert_raises(exception_class) → None`

Fail unless an exception of class `exception_class` is thrown by `callable` when invoked with arguments `args` and keyword arguments `kwargs`. If a different type of exception is thrown, it will not be caught, and the test case will be deemed to have suffered an error, exactly as for an unexpected exception.

Alternatively, *assert_raises* can be used as a context manager:

```
>>> from numpy.testing import assert_raises
>>> with assert_raises(ZeroDivisionError):
...     1 / 0
```

is equivalent to

```
>>> def div(x, y):
...     return x / y
>>> assert_raises(ZeroDivisionError, div, 1, 0)
```

`testing.assert_raises_regex(exception_class, expected_regexp, callable, *args, **kwargs)`
assert_raises_regex(exception_class, expected_regexp)

Fail unless an exception of class `exception_class` and with message that matches `expected_regexp` is thrown by `callable` when invoked with arguments `args` and keyword arguments `kwargs`.

Alternatively, can be used as a context manager like *assert_raises*.

`testing.assert_warns(warning_class, *args, **kwargs)`

Fail unless the given callable throws the specified warning.

A warning of class `warning_class` should be thrown by the callable when invoked with arguments `args` and keyword arguments `kwargs`. If a different type of warning is thrown, it will not be caught.

If called with all arguments other than the warning class omitted, may be used as a context manager:

```
with assert_warns(SomeWarning):
    do_something()
```

The ability to be used as a context manager is new in NumPy v1.11.0.

Deprecated since version 2.4: This is deprecated. Use `warnings.catch_warnings` or `pytest.warns` instead.

Parameters

warning_class

[class] The class defining the warning that *func* is expected to throw.

func

[callable, optional] Callable to test

***args**

[Arguments] Arguments for *func*.

****kwargs**

[Kwargs] Keyword arguments for *func*.

Returns

The value returned by *func*.

Examples

```
>>> import warnings
>>> def deprecated_func(num):
...     warnings.warn("Please upgrade", DeprecationWarning)
...     return num*num
>>> with np.testing.assert_warns(DeprecationWarning):
...     assert deprecated_func(4) == 16
>>> # or passing a func
>>> ret = np.testing.assert_warns(DeprecationWarning, deprecated_func, 4)
>>> assert ret == 16
```

`testing.assert_no_warnings(*args, **kwargs)`

Fail if the given callable produces any warnings.

If called with all arguments omitted, may be used as a context manager:

```
with assert_no_warnings():
    do_something()
```

The ability to be used as a context manager is new in NumPy v1.11.0.

Parameters

func

[callable] The callable to test.

***args**

[Arguments] Arguments passed to *func*.

****kwargs**

[Kwargs] Keyword arguments passed to *func*.

Returns

The value returned by *func*.

`testing.assert_no_gc_cycles(*args, **kwargs)`

Fail if the given callable produces any reference cycles.

If called with all arguments omitted, may be used as a context manager:

```
with assert_no_gc_cycles():
    do_something()
```

Parameters

func

[callable] The callable to test.

***args**

[Arguments] Arguments passed to *func*.

****kwargs**

[Kwargs] Keyword arguments passed to *func*.

Returns

Nothing. The result is deliberately discarded to ensure that all cycles are found.

`testing.assert_string_equal(actual, desired)`

Test if two strings are equal.

If the given strings are equal, `assert_string_equal` does nothing. If they are not equal, an `AssertionError` is raised, and the diff between the strings is shown.

Parameters

actual

[str] The string to test for equality against the expected string.

desired

[str] The expected string.

Examples

```
>>> np.testing.assert_string_equal('abc', 'abc')
>>> np.testing.assert_string_equal('abc', 'abcd')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
...
AssertionError: Differences in strings:
- abc+ abcd?      +
```

Asserts (not recommended)

It is recommended to use one of `assert_allclose`, `assert_array_almost_equal_nulp` or `assert_array_max_ulp` instead of these functions for more consistent floating point comparisons.

<code>assert_(val[, msg])</code>	Assert that works in release mode.
<code>assert_almost_equal(actual, desired[, ...])</code>	Raises an AssertionError if two items are not equal up to desired precision.
<code>assert_approx_equal(actual, desired[, ...])</code>	Raises an AssertionError if two items are not equal up to significant digits.
<code>assert_array_almost_equal(actual, desired[, ...])</code>	Raises an AssertionError if two objects are not equal up to desired precision.
<code>print_assert_equal(test_string, actual, desired)</code>	Test if two objects are equal, and print an error message if test fails.

`testing.assert_(val, msg="")`

Assert that works in release mode. Accepts callable msg to allow deferring evaluation until failure.

The Python built-in `assert` does not work when executing code in optimized mode (the `-O` flag) - no byte-code is generated for it.

For documentation on usage, refer to the Python documentation.

`testing.assert_almost_equal(actual, desired, decimal=7, err_msg="", verbose=True)`

Raises an AssertionError if two items are not equal up to desired precision.

Note: It is recommended to use one of `assert_allclose`, `assert_array_almost_equal_nulp` or `assert_array_max_ulp` instead of this function for more consistent floating point comparisons.

The test verifies that the elements of *actual* and *desired* satisfy:

```
abs(desired-actual) < float64(1.5 * 10**(-decimal))
```

That is a looser test than originally documented, but agrees with what the actual implementation in `assert_array_almost_equal` did up to rounding vagaries. An exception is raised at conflicting values. For ndarrays this delegates to `assert_array_almost_equal`

Parameters

actual

[array_like] The object to check.

desired

[array_like] The expected object.

decimal

[int, optional] Desired precision, default is 7.

err_msg

[str, optional] The error message to be printed in case of failure.

verbose

[bool, optional] If True, the conflicting values are appended to the error message.

Raises

AssertionError

If actual and desired are not equal up to specified precision.

See also:

[`assert\_allclose`](#)

Compare two array_like objects for equality with desired relative and/or absolute precision.

[`assert\_array\_almost\_equal\_nulp`](#), [`assert\_array\_max\_ulp`](#), [`assert\_equal`](#)

Examples

```
>>> from numpy.testing import assert_almost_equal
>>> assert_almost_equal(2.333333333333, 2.33333334)
>>> assert_almost_equal(2.333333333333, 2.33333334, decimal=10)
Traceback (most recent call last):
...
AssertionError:
Arrays are not almost equal to 10 decimals
ACTUAL: 2.333333333333
DESIRED: 2.33333334
```

```
>>> assert_almost_equal(np.array([1.0, 2.333333333333]),
...                     np.array([1.0, 2.33333334]), decimal=9)
Traceback (most recent call last):
...
AssertionError:
Arrays are not almost equal to 9 decimals

Mismatched elements: 1 / 2 (50%)
Mismatch at index:
 [1]: 2.333333333333 (ACTUAL), 2.33333334 (DESIRED)
Max absolute difference among violations: 6.66669964e-09
Max relative difference among violations: 2.85715698e-09
ACTUAL: array([1.          , 2.33333333])
DESIRED: array([1.          , 2.33333334])
```

testing.[**assert_approx_equal**](#) (*actual, desired, significant=7, err_msg="", verbose=True*)

Raises an AssertionError if two items are not equal up to significant digits.

Note: It is recommended to use one of [`assert\_allclose`](#), [`assert\_array\_almost\_equal\_nulp`](#) or [`assert\_array\_max\_ulp`](#) instead of this function for more consistent floating point comparisons.

Given two numbers, check that they are approximately equal. Approximately equal is defined as the number of significant digits that agree.

Parameters

actual

[scalar] The object to check.

desired

[scalar] The expected object.

significant

[int, optional] Desired precision, default is 7.

err_msg

[str, optional] The error message to be printed in case of failure.

verbose

[bool, optional] If True, the conflicting values are appended to the error message.

Raises**AssertionError**

If actual and desired are not equal up to specified precision.

See also:**`assert_allclose`**

Compare two array_like objects for equality with desired relative and/or absolute precision.

`assert_array_almost_equal_nulp`, `assert_array_max_ulp`, `assert_equal`**Examples**

```
>>> np.testing.assert_approx_equal(0.12345677777777e-20, 0.1234567e-20)
>>> np.testing.assert_approx_equal(0.12345670e-20, 0.12345671e-20,
...                               significant=8)
>>> np.testing.assert_approx_equal(0.12345670e-20, 0.12345672e-20,
...                               significant=8)
Traceback (most recent call last):
...
AssertionError:
Items are not equal to 8 significant digits:
ACTUAL: 1.234567e-21
DESIRED: 1.2345672e-21
```

the evaluated condition that raises the exception is

```
>>> abs(0.12345670e-20/1e-21 - 0.12345672e-20/1e-21) >= 10**-(8-1)
True
```

`testing.assert_array_almost_equal(actual, desired, decimal=6, err_msg="", verbose=True)`

Raises an AssertionError if two objects are not equal up to desired precision.

Note: It is recommended to use one of `assert_allclose`, `assert_array_almost_equal_nulp` or `assert_array_max_ulp` instead of this function for more consistent floating point comparisons.

The test verifies identical shapes and that the elements of `actual` and `desired` satisfy:

```
abs(desired-actual) < 1.5 * 10**(-decimal)
```

That is a looser test than originally documented, but agrees with what the actual implementation did up to rounding vagaries. An exception is raised at shape mismatch or conflicting values. In contrast to the standard usage in numpy, NaNs are compared like numbers, no assertion is raised if both objects have NaNs in the same positions.

Parameters**actual**

[array_like] The actual object to check.

desired

[array_like] The desired, expected object.

decimal

[int, optional] Desired precision, default is 6.

err_msg

[str, optional] The error message to be printed in case of failure.

verbose

[bool, optional] If True, the conflicting values are appended to the error message.

Raises**AssertionError**

If actual and desired are not equal up to specified precision.

See also:***assert_allclose***

Compare two array_like objects for equality with desired relative and/or absolute precision.

assert_array_almost_equal_nulp*, *assert_array_max_ulp*, *assert_equal**Examples**

the first assert does not raise an exception

```
>>> np.testing.assert_array_almost_equal([1.0, 2.333, np.nan],
...                                     [1.0, 2.333, np.nan])
```

```
>>> np.testing.assert_array_almost_equal([1.0, 2.33333, np.nan],
...                                     [1.0, 2.33339, np.nan], decimal=5)
Traceback (most recent call last):
...
AssertionError:
Arrays are not almost equal to 5 decimals

Mismatched elements: 1 / 3 (33.3%)
Mismatch at index:
 [1]: 2.33333 (ACTUAL), 2.33339 (DESIRED)
Max absolute difference among violations: 6.e-05
Max relative difference among violations: 2.57136612e-05
ACTUAL: array([1.      , 2.33333,   nan])
DESIRED: array([1.      , 2.33339,   nan])
```

```
>>> np.testing.assert_array_almost_equal([1.0, 2.33333, np.nan],
...                                     [1.0, 2.33333, 5], decimal=5)
Traceback (most recent call last):
...
AssertionError:
Arrays are not almost equal to 5 decimals

nan location mismatch:
ACTUAL: array([1.      , 2.33333,   nan])
DESIRED: array([1.      , 2.33333, 5.      ])
```

testing.**print_assert_equal** (*test_string*, *actual*, *desired*)

Test if two objects are equal, and print an error message if test fails.

The test is performed with `actual == desired`.

Parameters

- test_string**
[str] The message supplied to `AssertionError`.
- actual**
[object] The object to test for equality against *desired*.
- desired**
[object] The expected result.

Examples

```
>>> np.testing.print_assert_equal('Test XYZ of func xyz', [0, 1], [0, 1])
>>> np.testing.print_assert_equal('Test XYZ of func xyz', [0, 1], [0, 2])
Traceback (most recent call last):
...
AssertionError: Test XYZ of func xyz failed
ACTUAL:
[0, 1]
DESIRED:
[0, 2]
```

Decorators

<code>decorate_methods(cls, decorator[, testmatch])</code>	Apply a decorator to all methods in a class matching a regular expression.
--	--

`testing.decorate_methods` (*cls*, *decorator*, *testmatch=None*)

Apply a decorator to all methods in a class matching a regular expression.

The given decorator is applied to all public methods of *cls* that are matched by the regular expression *testmatch* (`testmatch.search(methodname)`). Methods that are private, i.e. start with an underscore, are ignored.

Parameters

- cls**
[class] Class whose methods to decorate.
- decorator**
[function] Decorator to apply to methods
- testmatch**
[compiled regexp or str, optional] The regular expression. Default value is `None`, in which case the nose default (`re.compile(r'(?!^|[\b_\.%s-])[Tt]est' % os.sep)`) is used. If *testmatch* is a string, it is compiled to a regular expression first.

Test running

<code>clear_and_catch_warnings([record, modules])</code>	Context manager that resets warning registry for catching warnings
<code>measure(code_str[, times, label])</code>	Return elapsed time for executing code in the namespace of the caller.
<code>rundocs([filename, raise_on_error])</code>	Run doctests found in the given file.
<code>suppress_warnings([forwarding_rule, _warn])</code>	Context manager and decorator doing much the same as <code>warnings.catch_warnings</code> .

class `numpy.testing.clear_and_catch_warnings` (*record=False, modules=()*)

Context manager that resets warning registry for catching warnings

Warnings can be slippery, because, whenever a warning is triggered, Python adds a `__warningregistry__` member to the *calling* module. This makes it impossible to retrigger the warning in this module, whatever you put in the warnings filters. This context manager accepts a sequence of *modules* as a keyword argument to its constructor and:

- stores and removes any `__warningregistry__` entries in given *modules* on entry;
- resets `__warningregistry__` to its previous state on exit.

This makes it possible to trigger any warning afresh inside the context manager without disturbing the state of warnings outside.

For compatibility with Python, please consider all arguments to be keyword-only.

Parameters

record

[bool, optional] Specifies whether warnings should be captured by a custom implementation of `warnings.showwarning()` and be appended to a list returned by the context manager. Otherwise None is returned by the context manager. The objects appended to the list are arguments whose attributes mirror the arguments to `showwarning()`.

modules

[sequence, optional] Sequence of modules for which to reset warnings registry on entry and restore on exit. To work correctly, all ‘ignore’ filters should filter by one of these modules.

Examples

```
>>> import warnings
>>> with np.testing.clear_and_catch_warnings(
...     modules=[np._core.fromnumeric]):
...     warnings.simplefilter('always')
...     warnings.filterwarnings('ignore', module='np._core.fromnumeric')
...     # do something that raises a warning but ignore those in
...     # np._core.fromnumeric
```

`testing.measure` (*code_str, times=1, label=None*)

Return elapsed time for executing code in the namespace of the caller.

The supplied code string is compiled with the Python builtin `compile`. The precision of the timing is 10 milliseconds. If the code will execute fast on this timescale, it can be executed many times to get reasonable timing accuracy.

Parameters

code_str

[str] The code to be timed.

times

[int, optional] The number of times the code is executed. Default is 1. The code is only compiled once.

label

[str, optional] A label to identify *code_str* with. This is passed into `compile` as the second argument (for run-time error messages).

Returns**elapsed**

[float] Total elapsed time in seconds for executing *code_str* *times* times.

Examples

```
>>> times = 10
>>> etime = np.testing.measure('for i in range(1000): np.sqrt(i**2)', times=times)
>>> print("Time for a single execution : ", etime / times, "s")
Time for a single execution : 0.005 s
```

`testing.rundocs` (*filename=None, raise_on_error=True*)

Run doctests found in the given file.

By default *rundocs* raises an `AssertionError` on failure.

Parameters**filename**

[str] The path to the file for which the doctests are run.

raise_on_error

[bool] Whether to raise an `AssertionError` when a doctest fails. Default is `True`.

Notes

The doctests can be run by the user/developer by adding the `doctests` argument to the `test()` call. For example, to run all tests (including doctests) for `numpy.lib`:

```
>>> np.lib.test(doctests=True)
```

class `numpy.testing.suppress_warnings` (*forwarding_rule='always', _warn=True*)

Context manager and decorator doing much the same as `warnings.catch_warnings`.

However, it also provides a filter mechanism to work around <https://bugs.python.org/issue4180>.

This bug causes Python before 3.4 to not reliably show warnings again after they have been ignored once (even within `catch_warnings`). It means that no “ignore” filter can be used easily, since following tests might need to see the warning. Additionally it allows easier specificity for testing warnings and can be nested.

Deprecated since version 2.4: This is deprecated. Use `warnings.filterwarnings` or `pytest.filterwarnings` instead.

Parameters

forwarding_rule

[str, optional] One of “always”, “once”, “module”, or “location”. Analogous to the usual warnings module filter mode, it is useful to reduce noise mostly on the outmost level. Unsuppressed and unrecorded warnings will be forwarded based on this rule. Defaults to “always”. “location” is equivalent to the warnings “default”, match by exact location the warning warning originated from.

Methods

<code>__call__(func)</code>	Function decorator to apply certain suppressions to a whole function.
<code>filter([category, message, module])</code>	Add a new suppressing filter or apply it if the state is entered.
<code>record([category, message, module])</code>	Append a new recording filter or apply it if the state is entered.

method

`testing.suppress_warnings.__call__(func)`

Function decorator to apply certain suppressions to a whole function.

method

`testing.suppress_warnings.filter(category=<class 'Warning'>, message="", module=None)`

Add a new suppressing filter or apply it if the state is entered.

Parameters**category**

[class, optional] Warning class to filter

message

[string, optional] Regular expression matching the warning message.

module

[module, optional] Module to filter for. Note that the module (and its file) must match exactly and cannot be a submodule. This may make it unreliable for external modules.

Notes

When added within a context, filters are only added inside the context and will be forgotten when the context is exited.

method

`testing.suppress_warnings.record(category=<class 'Warning'>, message="", module=None)`

Append a new recording filter or apply it if the state is entered.

All warnings matching will be appended to the `log` attribute.

Parameters**category**

[class, optional] Warning class to filter

message

[string, optional] Regular expression matching the warning message.

module

[module, optional] Module to filter for. Note that the module (and its file) must match exactly and cannot be a submodule. This may make it unreliable for external modules.

Returns**log**

[list] A list which will be filled with all matched warnings.

Notes

When added within a context, filters are only added inside the context and will be forgotten when the context is exited.

Notes

Filters added inside the context manager will be discarded again when leaving it. Upon entering all filters defined outside a context will be applied automatically.

When a recording filter is added, matching warnings are stored in the `log` attribute as well as in the list returned by `record`.

If filters are added and the `module` keyword is given, the warning registry of this module will additionally be cleared when applying it, entering the context, or exiting it. This could cause warnings to appear a second time after leaving the context if they were configured to be printed once (default) and were already printed before the context was entered.

Nesting this context manager will work as expected when the forwarding rule is “always” (default). Unfiltered and unrecorded warnings will be passed out and be matched by the outer level. On the outmost level they will be printed (or caught by another warnings context). The forwarding rule argument can modify this behaviour.

Like `catch_warnings` this context manager is not threadsafe.

Examples

With a context manager:

```
with np.testing.suppress_warnings() as sup:
    sup.filter(DeprecationWarning, "Some text")
    sup.filter(module=np.ma.core)
    log = sup.record(FutureWarning, "Does this occur?")
    command_giving_warnings()
    # The FutureWarning was given once, the filtered warnings were
    # ignored. All other warnings abide outside settings (may be
    # printed/error)
    assert_(len(log) == 1)
    assert_(len(sup.log) == 1) # also stored in log attribute
```

Or as a decorator:

```
sup = np.testing.suppress_warnings()
sup.filter(module=np.ma.core) # module must match exactly
@sup
def some_function():
    # do something which causes a warning in np.ma.core
    pass
```

Testing custom array containers (`numpy.testing.overrides`)

These functions can be useful when testing custom array container implementations which make use of `__array_ufunc__`/`__array_function__`.

<code>allows_array_function_override(func)</code>	Determine if a Numpy function can be overridden via <code>__array_function__</code>
<code>allows_array_ufunc_override(func)</code>	Determine if a function can be overridden via <code>__array_ufunc__</code>
<code>get_overridable_numpy_ufuncs()</code>	List all numpy ufuncs overridable via <code>__array_ufunc__</code>
<code>get_overridable_numpy_array_functions()</code>	List all numpy functions overridable via <code>__array_function__</code>

`testing.overrides.allows_array_function_override(func)`

Determine if a Numpy function can be overridden via `__array_function__`

Parameters

func

[callable] Function that may be overridable via `__array_function__`

Returns

bool

True if *func* is a function in the Numpy API that is overridable via `__array_function__` and *False* otherwise.

`testing.overrides.allows_array_ufunc_override(func)`

Determine if a function can be overridden via `__array_ufunc__`

Parameters

func

[callable] Function that may be overridable via `__array_ufunc__`

Returns

bool

True if *func* is overridable via `__array_ufunc__` and *False* otherwise.

Notes

This function is equivalent to `isinstance(func, np.ufunc)` and will work correctly for ufuncs defined outside of Numpy.

`testing.overrides.get_overridable_numpy_ufuncs()`

List all numpy ufuncs overridable via `__array_ufunc__`

Parameters

None

Returns

set

A set containing all overridable ufuncs in the public numpy API.

```
testing.overrides.get_overridable_numpy_array_functions()
```

List all numpy functions overridable via `__array_function__`

Parameters

None

Returns

set

A set containing all functions in the public numpy API that are overridable via `__array_function__`.

Guidelines

Testing guidelines

Introduction

Until the 1.15 release, NumPy used the `nose` testing framework, it now uses the `pytest` framework. The older framework is still maintained in order to support downstream projects that use the old numpy framework, but all tests for NumPy should use `pytest`.

Our goal is that every module and package in NumPy should have a thorough set of unit tests. These tests should exercise the full functionality of a given routine as well as its robustness to erroneous or unexpected input arguments. Well-designed tests with good coverage make an enormous difference to the ease of refactoring. Whenever a new bug is found in a routine, you should write a new test for that specific case and add it to the test suite to prevent that bug from creeping back in unnoticed.

Note: SciPy uses the testing framework from `numpy.testing`, so all of the NumPy examples shown below are also applicable to SciPy

Testing NumPy

NumPy can be tested in a number of ways, choose any way you feel comfortable.

Running tests from inside Python

You can test an installed NumPy by `numpy.test`, for example, To run NumPy's full test suite, use the following:

```
>>> import numpy
>>> numpy.test(label='slow')
```

The test method may take two or more arguments; the first `label` is a string specifying what should be tested and the second `verbose` is an integer giving the level of output verbosity. See the docstring `numpy.test` for details. The default value for `label` is 'fast' - which will run the standard tests. The string 'full' will run the full battery of tests, including those identified as being slow to run. If `verbose` is 1 or less, the tests will just show information messages about the tests that are run; but if it is greater than 1, then the tests will also provide warnings on missing tests. So if you want to run every test and get messages about which modules don't have tests:

```
>>> numpy.test(label='full', verbose=2) # or numpy.test('full', 2)
```

Finally, if you are only interested in testing a subset of NumPy, for example, the `_core` module, use the following:

```
>>> numpy._core.test()
```

Running tests from the command line

If you want to build NumPy in order to work on NumPy itself, use the spin utility.

To run NumPy's full test suite:

```
$ spin test -m full
```

Testing a subset of NumPy:

```
$ spin test -t numpy/_core/tests
```

For detailed info on testing, see [testing-builds](#)

Running tests in multiple threads

To help with stress testing NumPy for thread safety, the test suite can be run under `pytest-run-parallel`. To install `pytest-run-parallel`:

```
$ pip install pytest-run-parallel
```

To run the test suite in multiple threads:

```
$ spin test -p auto # have pytest-run-parallel detect the number of available cores
$ spin test -p 4 # run each test under 4 threads
$ spin test -p auto -- --skip-thread-unsafe=true # run ONLY tests that are thread-safe
```

When you write new tests, it is worth testing to make sure they do not fail under `pytest-run-parallel`, since the CI jobs make use of it. Some tips on how to write thread-safe tests can be found [here](#).

Note: Ideally you should run `pytest-run-parallel` using a [free-threaded build of Python](#) that is 3.14 or higher. If you decide to use a version of Python that is not free-threaded, you will need to set the environment variables `PYTHON_CONTEXT_AWARE_WARNINGS` and `PYTHON_THREAD_INHERIT_CONTEXT` to 1.

Running doctests

NumPy documentation contains code examples, “doctests”. To check that the examples are correct, install the `scipy-doctest` package:

```
$ pip install scipy-doctest
```

and run one of:

```
$ spin check-docs -v
$ spin check-docs numpy/linalg
$ spin check-docs -- -k 'det and not slogdet'
```

Note that the doctests are not run when you use `spin test`.

Other methods of running tests

Run tests using your favourite IDE such as [vscode](#) or [pycharm](#)

Writing your own tests

If you are writing code that you'd like to become part of NumPy, please write the tests as you develop your code. Every Python module, extension module, or subpackage in the NumPy package directory should have a corresponding `test_<name>.py` file. Pytest examines these files for test methods (named `test*`) and test classes (named `Test*`).

Suppose you have a NumPy module `numpy/xxx/yyy.py` containing a function `zzz()`. To test this function you would create a test module called `test_yyy.py`. If you only need to test one aspect of `zzz`, you can simply add a test function:

```
def test_zzz():
    assert zzz() == 'Hello from zzz'
```

More often, we need to group a number of tests together, so we create a test class:

```
# import xxx symbols
from numpy.xxx.yyy import zzz
import pytest

class TestZzz:
    def test_simple(self):
        assert zzz() == 'Hello from zzz'

    def test_invalid_parameter(self):
        with pytest.raises(ValueError, match='.*some matching regex.*'):
            ...
```

Within these test methods, the `assert` statement or a specialized assertion function is used to test whether a certain assumption is valid. If the assertion fails, the test fails. Common assertion functions include:

- `numpy.testing.assert_equal` for testing exact elementwise equality between a result array and a reference,
- `numpy.testing.assert_allclose` for testing near elementwise equality between a result array and a reference (i.e. with specified relative and absolute tolerances), and
- `numpy.testing.assert_array_less` for testing (strict) elementwise ordering between a result array and a reference.

By default, these assertion functions only compare the numerical values in the arrays. Consider using the `strict=True` option to check the array dtype and shape, too.

When you need custom assertions, use the Python `assert` statement. Note that `pytest` internally rewrites `assert` statements to give informative output when it fails, so it should be preferred over the legacy variant `numpy.testing.assert_`. Whereas plain `assert` statements are ignored when running Python in optimized mode with `-O`, this is not an issue when running tests with `pytest`.

Similarly, the `pytest` functions `pytest.raises` and `pytest.warns` should be preferred over their legacy counterparts `numpy.testing.assert_raises` and `numpy.testing.assert_warns`, which are more broadly used. These versions also accept a `match` parameter, which should always be used to precisely target the intended warning or error.

Note that `test_` functions or methods should not have a docstring, because that makes it hard to identify the test from the output of running the test suite with `verbose=2` (or similar verbosity setting). Use plain comments (`#`) to describe

the intent of the test and help the unfamiliar reader to interpret the code.

Also, since much of NumPy is legacy code that was originally written without unit tests, there are still several modules that don't have tests yet. Please feel free to choose one of these modules and develop tests for it.

Using C code in tests

NumPy exposes a rich *C-API*. These are tested using c-extension modules written “as-if” they know nothing about the internals of NumPy, rather using the official C-API interfaces only. Examples of such modules are tests for a user-defined `rational` dtype in `_rational_tests` or the ufunc machinery tests in `_umath_tests` which are part of the binary distribution. Starting from version 1.21, you can also write snippets of C code in tests that will be compiled locally into c-extension modules and loaded into python.

```
numpy.testing.extbuild.build_and_import_extension(modname, functions, *, prologue="",  
                                                  build_dir=None, include_dirs=None,  
                                                  more_init="")
```

Build and imports a c-extension module *modname* from a list of function fragments *functions*.

Parameters

functions

[list of fragments] Each fragment is a sequence of `func_name`, calling convention, snippet.

prologue

[string] Code to precede the rest, usually extra `#include` or `#define` macros.

build_dir

[pathlib.Path] Where to build the module, usually a temporary directory

include_dirs

[list] Extra directories to find include files when compiling

more_init

[string] Code to appear in the module `PyMODINIT_FUNC`

Returns

out: module

The module will have been loaded and is ready for use

Examples

```
>>> functions = [("test_bytes", "METH_O", """  
    if ( !PyBytesCheck(args)) {  
        Py_RETURN_FALSE;  
    }  
    Py_RETURN_TRUE;  
    """)]  
>>> mod = build_and_import_extension("testme", functions)  
>>> assert not mod.test_bytes('abc')  
>>> assert mod.test_bytes(b'abc')
```

Labeling tests

Unlabeled tests like the ones above are run in the default `numpy.test()` run. If you want to label your test as slow - and therefore reserved for a full `numpy.test(label='full')` run, you can label it with `pytest.mark.slow`:

```
import pytest

@pytest.mark.slow
def test_big(self):
    print('Big, slow test')
```

Similarly for methods:

```
class test_zzz:
    @pytest.mark.slow
    def test_simple(self):
        assert_(zzz() == 'Hello from zzz')
```

Setup and teardown methods

NumPy originally used xunit setup and teardown, a feature of `pytest`. We now encourage the usage of setup and teardown methods that are called explicitly by the tests that need them:

```
class TestMe:
    def setup(self):
        print('doing setup')
        return 1

    def teardown(self):
        print('doing teardown')

    def test_xyz(self):
        x = self.setup()
        assert x == 1
        self.teardown()
```

This approach is thread-safe, ensuring tests can run under `pytest-run-parallel`. Using `pytest` setup fixtures (such as xunit setup methods) is generally not thread-safe and will likely cause thread-safety test failures.

`pytest` supports more general fixture at various scopes which may be used automatically via special arguments. For example, the special argument name `tmp_path` is used in tests to create temporary directories. However, fixtures should be used sparingly.

Parametric tests

One very nice feature of `pytest` is the ease of testing across a range of parameter values using the `pytest.mark.parametrize` decorator. For example, suppose you wish to test `linalg.solve` for all combinations of three array sizes and two data types:

```
@pytest.mark.parametrize('dimensionality', [3, 10, 25])
@pytest.mark.parametrize('dtype', [np.float32, np.float64])
def test_solve(dimensionality, dtype):
    np.random.seed(842523)
    A = np.random.random(size=(dimensionality, dimensionality)).astype(dtype)
```

(continues on next page)

(continued from previous page)

```
b = np.random.random(size=dimensionality).astype(dtype)
x = np.linalg.solve(A, b)
eps = np.finfo(dtype).eps
assert_allclose(A @ x, b, rtol=eps*1e2, atol=0)
assert x.dtype == np.dtype(dtype)
```

Doctests

Doctests are a convenient way of documenting the behavior of a function and allowing that behavior to be tested at the same time. The output of an interactive Python session can be included in the docstring of a function, and the test framework can run the example and compare the actual output to the expected output.

The doctests can be run by adding the `doctests` argument to the `test()` call; for example, to run all tests (including doctests) for `numpy.lib`:

```
>>> import numpy as np
>>> np.lib.test(doctests=True)
```

The doctests are run as if they are in a fresh Python instance which has executed `import numpy as np`. Tests that are part of a NumPy subpackage will have that subpackage already imported. E.g. for a test in `numpy/linalg/tests/`, the namespace will be created such that `from numpy import linalg` has already executed.

tests/

Rather than keeping the code and the tests in the same directory, we put all the tests for a given subpackage in a `tests/` subdirectory. For our example, if it doesn't already exist you will need to create a `tests/` directory in `numpy/xxx/`. So the path for `test_yyy.py` is `numpy/xxx/tests/test_yyy.py`.

Once the `numpy/xxx/tests/test_yyy.py` is written, it's possible to run the tests by going to the `tests/` directory and typing:

```
python test_yyy.py
```

Or if you add `numpy/xxx/tests/` to the Python path, you could run the tests interactively in the interpreter like this:

```
>>> import test_yyy
>>> test_yyy.test()
```

__init__.py and setup.py

Usually, however, adding the `tests/` directory to the python path isn't desirable. Instead it would be better to invoke the test straight from the module `xxx`. To this end, simply place the following lines at the end of your package's `__init__.py` file:

```
...
def test(level=1, verbosity=1):
    from numpy.testing import Tester
    return Tester().test(level, verbosity)
```

You will also need to add the `tests` directory in the configuration section of your `setup.py`:

```
...
def configuration(parent_package='', top_path=None):
    ...
    config.add_subpackage('tests')
    return config
...
```

Now you can do the following to test your module:

```
>>> import numpy
>>> numpy.xxx.test()
```

Also, when invoking the entire NumPy test suite, your tests will be found and run:

```
>>> import numpy
>>> numpy.test()
# your tests are included and run automatically!
```

Tips & Tricks

Known failures & skipping tests

Sometimes you might want to skip a test or mark it as a known failure, such as when the test suite is being written before the code it's meant to test, or if a test only fails on a particular architecture.

To skip a test, simply use `skipif`:

```
import pytest

@pytest.mark.skipif(SkipMyTest, reason="Skipping this test because...")
def test_something(foo):
    ...
```

The test is marked as skipped if `SkipMyTest` evaluates to nonzero, and the message in verbose test output is the second argument given to `skipif`. Similarly, a test can be marked as a known failure by using `xfail`:

```
import pytest

@pytest.mark.xfail(MyTestFails, reason="This test is known to fail because...")
def test_something_else(foo):
    ...
```

Of course, a test can be unconditionally skipped or marked as a known failure by using `skip` or `xfail` without argument, respectively.

A total of the number of skipped and known failing tests is displayed at the end of the test run. Skipped tests are marked as 'S' in the test results (or 'SKIPPED' for `verbose > 1`), and known failing tests are marked as 'x' (or 'XFAIL' if `verbose > 1`).

Tests on random data

Tests on random data are good, but since test failures are meant to expose new bugs or regressions, a test that passes most of the time but fails occasionally with no code changes is not helpful. Make the random data deterministic by setting the random number seed before generating it. Use `rng = numpy.random.RandomState(some_number)` to set a seed on a local instance of `numpy.random.RandomState`.

Alternatively, you can use `Hypothesis` to generate arbitrary data. `Hypothesis` manages both Python's and Numpy's random seeds for you, and provides a very concise and powerful way to describe data (including `hypothesis.extra.numpy`, e.g. for a set of mutually-broadcastable shapes).

The advantages over random generation include tools to replay and share failures without requiring a fixed seed, reporting *minimal* examples for each failure, and better-than-naive-random techniques for triggering bugs.

Writing thread-safe tests

Writing thread-safe tests may require some trial-and-error. Generally you should follow the guidelines stated so far, especially when it comes to *setup methods* and *seeding random data*. Explicit setup and the usage of local RNG are thread-safe practices. Here are tips for some other common problems you may run into.

Using `pytest.mark.parametrize` may occasionally cause thread-safety issues. To fix this, you can use `copy()`:

```
@pytest.mark.parametrize('dimensionality', [3, 10, 25])
@pytest.mark.parametrize('dtype', [np.float32, np.float64])
def test_solve(dimensionality, dtype):
    dimen = dimensionality.copy()
    d = dtype.copy()
    # use these copied variables instead
    ...
```

If you are testing something that is inherently thread-unsafe, you can label your test with `pytest.mark.thread_unsafe` so that it will run under a single thread and not cause test failures:

```
@pytest.mark.thread_unsafe(reason="reason this test is thread-unsafe")
def test_thread_unsafe():
    ...
```

Some examples of what should be labeled as thread-unsafe:

- Usage of `sys.stdout` and `sys.stderr`
- Mutation of global data, like docstrings, modules, garbage collectors, etc.
- Tests that require a lot of memory, since they could cause crashes.

Additionally, some `pytest` fixtures are thread-unsafe, such as `monkeypatch` and `capsys`. However, `pytest-run-parallel` will automatically mark these as thread-unsafe if you decide to use them. Some fixtures have been patched to be thread-safe, like `tmp_path`.

Documentation for `numpy.test`

`numpy.test` (*label='fast', verbose=1, extra_argv=None, doctests=False, coverage=False, durations=-1, tests=None*)

Pytest test runner.

A test function is typically added to a package's `__init__.py` like so:

```
from numpy._pytesttester import PytestTester
test = PytestTester(__name__).test
del PytestTester
```

Calling this test function finds and runs all tests associated with the module and all its sub-modules.

Parameters

`module_name`

[module name] The name of the module to test.

Attributes

`module_name`

[str] Full path to the package to test.

Notes

Unlike the previous `nose`-based implementation, this class is not publicly exposed as it performs some `numpy`-specific warning suppression.

Typing (`numpy.typing`)

New in version 1.20.

Large parts of the NumPy API have [PEP 484](#)-style type annotations. In addition a number of type aliases are available to users, most prominently the two below:

- `ArrayLike`: objects that can be converted to arrays
- `DTypeLike`: objects that can be converted to dtypes

Mypy plugin

New in version 1.21. A `mypy` plugin for managing a number of platform-specific annotations. Its functionality can be split into three distinct parts:

- Assigning the (platform-dependent) precisions of certain `number` subclasses, including the likes of `int_`, `intp` and `longlong`. See the documentation on *scalar types* for a comprehensive overview of the affected classes. Without the plugin the precision of all relevant classes will be inferred as `Any`.
- Removing all extended-precision `number` subclasses that are unavailable for the platform in question. Most notably this includes the likes of `float128` and `complex256`. Without the plugin *all* extended-precision types will, as far as `mypy` is concerned, be available to all platforms.
- Assigning the (platform-dependent) precision of `c_intp`. Without the plugin the type will default to `ctypes.c_int64`.

New in version 1.22.

Deprecated since version 2.3: The `numpy.typing.mypy_plugin` entry-point is deprecated in favor of platform-agnostic static type inference. Remove `numpy.typing.mypy_plugin` from the `plugins` section of your `mypy` configuration; if that surfaces new errors, please open an issue with a minimal reproducer.

Examples

To enable the plugin, one must add it to their mypy configuration file:

```
[mypy]
plugins = numpy.typing.mypy_plugin
```

Differences from the runtime NumPy API

NumPy is very flexible. Trying to describe the full range of possibilities statically would result in types that are not very helpful. For that reason, the typed NumPy API is often stricter than the runtime NumPy API. This section describes some notable differences.

ArrayLike

The *ArrayLike* type tries to avoid creating object arrays. For example,

```
>>> np.array(x**2 for x in range(10))
array(<generator object <genexpr> at ...>, dtype=object)
```

is valid NumPy code which will create a 0-dimensional object array. Type checkers will complain about the above example when using the NumPy types however. If you really intended to do the above, then you can either use a `# type: ignore` comment:

```
>>> np.array(x**2 for x in range(10)) # type: ignore
```

or explicitly type the array like object as *Any*:

```
>>> from typing import Any
>>> array_like: Any = (x**2 for x in range(10))
>>> np.array(array_like)
array(<generator object <genexpr> at ...>, dtype=object)
```

DTypeLike

The *DTypeLike* type tries to avoid creation of dtype objects using dictionary of fields like below:

```
>>> x = np.dtype({"field1": (float, 1), "field2": (int, 3)})
```

Although this is valid NumPy code, the type checker will complain about it, since its usage is discouraged. Please see : *Data type objects*

Number precision

The precision of *numpy.number* subclasses is treated as an invariant generic parameter (see *NBitBase*), simplifying the annotating of processes involving precision-based casting.

```
>>> from typing import TypeVar
>>> import numpy as np
>>> import numpy.typing as npt

>>> T = TypeVar("T", bound=npt.NBitBase)
```

(continues on next page)

(continued from previous page)

```
>>> def func(a: np.floating[T], b: np.floating[T]) -> np.floating[T]:
...     ...
```

Consequently, the likes of `float16`, `float32` and `float64` are still sub-types of `floating`, but, contrary to runtime, they're not necessarily considered as sub-classes.

Deprecated since version 2.3: The `NBitBase` helper is deprecated and will be removed in a future release. Prefer expressing precision relationships via `typing.overload` or `TypeVar` definitions bounded by concrete scalar classes. For example:

```
from typing import TypeVar
import numpy as np

S = TypeVar("S", bound=np.floating)

def func(a: S, b: S) -> S:
    ...
```

or in the case of different input types mapping to different output types:

```
from typing import overload
import numpy as np

@overload
def phase(x: np.complex64) -> np.float32: ...
@overload
def phase(x: np.complex128) -> np.float64: ...
@overload
def phase(x: np.clongdouble) -> np.longdouble: ...
def phase(x: np.complexfloating) -> np.floating:
    ...
```

Timedelta64

The `timedelta64` class is not considered a subclass of `signedinteger`, the former only inheriting from `generic` while static type checking.

Record array dtypes

The dtype of `numpy.recarray`, and the *Creating record arrays* functions in general, can be specified in one of two ways:

- Directly via the `dtype` argument.
- With up to five helper arguments that operate via `numpy.rec.format_parser`: `formats`, `names`, `titles`, `aligned` and `byteorder`.

These two approaches are currently typed as being mutually exclusive, *i.e.* if `dtype` is specified then one may not specify `formats`. While this mutual exclusivity is not (strictly) enforced during runtime, combining both dtype specifiers can lead to unexpected or even downright buggy behavior.

API

ndarray

The `numpy.ndarray` class is a [generic type](#) that accepts two type arguments:

1. The type of `numpy.ndarray.shape`, which must be a *tuple* of *int*, e.g. `tuple[int, int]` (2-D shape) or `tuple[()]` (0-D shape). The default shape is `tuple[Any, ...]`, which represents an unknown shape with *any* number of dimensions. Currently, `Literal` ints or other more specific types are not supported.
2. The type of `numpy.ndarray.dtype`, which must be a subtype of `numpy.dtype` such as `numpy.dtype[numpy.float64]`. If omitted, it will default to `numpy.dtype[Any]`.

```
>>> import numpy as np

>>> type ImageRGB = np.ndarray[tuple[int, int, int], np.dtype[np.uint8]]
>>> type Vector[S: np.generic] = np.ndarray[tuple[int], np.dtype[S]]
```

`numpy.typing.ArrayLike = typing.Union[...]`

A `Union` representing objects that can be coerced into an `ndarray`.

Among others this includes the likes of:

- Scalars.
- (Nested) sequences.
- Objects implementing the `__array__` protocol.

New in version 1.20.

See Also

`array_like`:

Any scalar or sequence that can be interpreted as an `ndarray`.

Examples

```
>>> import numpy as np
>>> import numpy.typing as npt

>>> def as_array(a: npt.ArrayLike) -> np.ndarray:
...     return np.array(a)
```

`numpy.typing.DTypeLike = typing.Union[...]`

A `Union` representing objects that can be coerced into a `dtype`.

Among others this includes the likes of:

- `type` objects.
- Character codes or the names of `type` objects.
- Objects with the `.dtype` attribute.

New in version 1.20.

See Also

Specifying and constructing data types

A comprehensive overview of all objects that can be coerced into data types.

Examples

```
>>> import numpy as np
>>> import numpy.typing as npt

>>> def as_dtype(d: npt.DTypeLike) -> np.dtype:
...     return np.dtype(d)
```

`numpy.typing.NDArray` = `NDArray`

A `np.ndarray[tuple[Any, ...], np.dtype[ScalarT]]` type alias `generic` w.r.t. its `dtype` type.

Can be used during runtime for typing arrays with a given dtype and unspecified shape.

New in version 1.21.

Examples

```
>>> import numpy as np
>>> import numpy.typing as npt

>>> print(npt.NDArray)
NDArray

>>> print(npt.NDArray[np.float64])
NDArray[numpy.float64]

>>> NDArrayInt = npt.NDArray[np.int_]
>>> a: NDArrayInt = np.arange(10)

>>> def func(a: npt.ArrayLike) -> npt.NDArray[Any]:
...     return np.array(a)
```

class `numpy.typing.NBitBase`

A type representing *numpy.number* precision during static type checking.

Used exclusively for the purpose of static type checking, *NBitBase* represents the base of a hierarchical set of subclasses. Each subsequent subclass is herein used for representing a lower level of precision, *e.g.* 64Bit > 32Bit > 16Bit.

New in version 1.20.

Deprecated since version 2.3: Use `@typing.overload` or a `TypeVar` with a scalar-type as upper bound, instead.

Examples

Below is a typical usage example: *NBitBase* is herein used for annotating a function that takes a float and integer of arbitrary precision as arguments and returns a new float of whichever precision is largest (e.g. `np.float16 + np.int64 -> np.float64`).

```
>>> from typing import TYPE_CHECKING
>>> import numpy as np
>>> import numpy.typing as npt

>>> def add[S: npt.NBitBase, T: npt.NBitBase](
...     a: np.floating[S], b: np.integer[T]
... ) -> np.floating[S | T]:
...     return a + b

>>> a = np.float16()
>>> b = np.int64()
>>> out = add(a, b)

>>> if TYPE_CHECKING:
...     reveal_locals()
...     # note: Revealed local types are:
...     # note:     a: numpy.floating[numpy.typing._16Bit*]
...     # note:     b: numpy.signedinteger[numpy.typing._64Bit*]
...     # note:     out: numpy.floating[numpy.typing._64Bit*]
```

ctypes foreign function interface (`numpy.ctypeslib`)

`numpy.ctypeslib.as_array(obj, shape=None)`

Create a numpy array from a ctypes array or POINTER.

The numpy array shares the memory with the ctypes object.

The shape parameter must be given if converting from a ctypes POINTER. The shape parameter is ignored if converting from a ctypes array

Examples

Converting a ctypes integer array:

```
>>> import ctypes
>>> ctypes_array = (ctypes.c_int * 5)(0, 1, 2, 3, 4)
>>> np_array = np.ctypeslib.as_array(ctypes_array)
>>> np_array
array([0, 1, 2, 3, 4], dtype=int32)
```

Converting a ctypes POINTER:

```
>>> import ctypes
>>> buffer = (ctypes.c_int * 5)(0, 1, 2, 3, 4)
>>> pointer = ctypes.cast(buffer, ctypes.POINTER(ctypes.c_int))
>>> np_array = np.ctypeslib.as_array(pointer, (5,))
>>> np_array
array([0, 1, 2, 3, 4], dtype=int32)
```

`numpy.ctypeslib.as_ctypes` (*obj*)

Create and return a ctypes object from a numpy array. Actually anything that exposes the `__array_interface__` is accepted.

Examples

Create ctypes object from inferred int `np.array`:

```
>>> inferred_int_array = np.array([1, 2, 3])
>>> c_int_array = np.ctypeslib.as_ctypes(inferred_int_array)
>>> type(c_int_array)
<class 'c_long_Array_3'>
>>> c_int_array[:]
[1, 2, 3]
```

Create ctypes object from explicit 8 bit unsigned int `np.array`:

```
>>> exp_int_array = np.array([1, 2, 3], dtype=np.uint8)
>>> c_int_array = np.ctypeslib.as_ctypes(exp_int_array)
>>> type(c_int_array)
<class 'c_ubyte_Array_3'>
>>> c_int_array[:]
[1, 2, 3]
```

`numpy.ctypeslib.as_ctypes_type` (*dtype*)

Convert a dtype into a ctypes type.

Parameters

dtype

[dtype] The dtype to convert

Returns

ctype

A ctype scalar, union, array, or struct

Raises

NotImplementedError

If the conversion is not possible

Notes

This function does not losslessly round-trip in either direction.

`np.dtype(as_ctypes_type(dt))` will:

- insert padding fields
- reorder fields to be sorted by offset
- discard field titles

`as_ctypes_type(np.dtype(ctype))` will:

- discard the class names of `ctypes.Structures` and `ctypes.Unions`
- convert single-element `ctypes.Unions` into single-element `ctypes.Structures`

- insert padding fields

Examples

Converting a simple dtype:

```
>>> dt = np.dtype(np.int8)
>>> ctype = np.ctypeslib.as_ctypes_type(dt)
>>> ctype
<class 'ctypes.c_byte'>
```

Converting a structured dtype:

```
>>> dt = np.dtype([( 'x', 'i4'), ('y', 'f4')])
>>> ctype = np.ctypeslib.as_ctypes_type(dt)
>>> ctype
<class 'struct'>
```

`numpy.ctypeslib.load_library(libname, loader_path)`

It is possible to load a library using

```
>>> lib = ctypes.cdll[<full_path_name>]
```

But there are cross-platform considerations, such as library file extensions, plus the fact Windows will just load the first library it finds with that name. NumPy supplies the `load_library` function as a convenience.

Changed in version 1.20.0: Allow `libname` and `loader_path` to take any [path-like object](#).

Parameters

libname

[path-like] Name of the library, which can have 'lib' as a prefix, but without an extension.

loader_path

[path-like] Where the library can be found.

Returns

ctypes.cdll[libpath]

[library object] A ctypes library object

Raises

OSError

If there is no library with the expected extension, or the library is defective and cannot be loaded.

`numpy.ctypeslib.ndpointer(dtype=None, ndim=None, shape=None, flags=None)`

Array-checking `restype/argtypes`.

An `ndpointer` instance is used to describe an `ndarray` in `reatypes` and `argtypes` specifications. This approach is more flexible than using, for example, `POINTER(c_double)`, since several restrictions can be specified, which are verified upon calling the `ctypes` function. These include data type, number of dimensions, shape and flags. If a given array does not satisfy the specified restrictions, a `TypeError` is raised.

Parameters

dtype

[data-type, optional] Array data-type.

ndim

[int, optional] Number of array dimensions.

shape

[tuple of ints, optional] Array shape.

flags

[str or tuple of str] Array flags; may be one or more of:

- C_CONTIGUOUS / C / CONTIGUOUS
- F_CONTIGUOUS / F / FORTRAN
- OWNDATA / O
- WRITEABLE / W
- ALIGNED / A
- WRITEBACKIFCOPY / X

Returns**class**

[ndpointer type object] A type object, which is an `_ndtpr` instance containing dtype, ndim, shape and flags information.

Raises**TypeError**

If a given array does not satisfy the specified restrictions.

Examples

```
>>> clib.somefunc.argtypes = [np.ctypeslib.ndpointer(dtype=np.float64,
...                                                    ndim=1,
...                                                    flags='C_CONTIGUOUS')]
>>> clib.somefunc(np.array([1, 2, 3], dtype=np.float64))
...

```

class `numpy.ctypeslib.c_intp`

A `ctypes` signed integer type of the same size as `numpy.intp`.

Depending on the platform, it can be an alias for either `c_int`, `c_long` or `c_longlong`.

Data type classes (`numpy.dtypes`)

This module is home to specific dtypes related functionality and their classes. For more general information about dtypes, also see `numpy.dtype` and *Data type objects (dtype)*.

Similar to the builtin `types` module, this submodule defines types (classes) that are not widely used directly.

New in version NumPy: 1.25

The dtypes module is new in NumPy 1.25. Previously DType classes were only accessible indirectly.

DType classes

The following are the classes of the corresponding NumPy dtype instances and NumPy scalar types. The classes can be used in `isinstance` checks and can also be instantiated or used directly. Direct use of these classes is not typical, since their scalar counterparts (e.g. `np.float64`) or strings like `"float64"` can be used.

Boolean

`numpy.dtypes.BoolDType`

Bit-sized integers

`numpy.dtypes.Int8DType`

`numpy.dtypes.UInt8DType`

`numpy.dtypes.Int16DType`

`numpy.dtypes.UInt16DType`

`numpy.dtypes.Int32DType`

`numpy.dtypes.UInt32DType`

`numpy.dtypes.Int64DType`

`numpy.dtypes.UInt64DType`

C-named integers (may be aliases)

`numpy.dtypes.ByteDType`

`numpy.dtypes.UByteDType`

`numpy.dtypes.ShortDType`

`numpy.dtypes.UShortDType`

`numpy.dtypes.IntDType`

`numpy.dtypes.UIntDType`

`numpy.dtypes.LongDType`

`numpy.dtypes.ULongDType`

`numpy.dtypes.LongLongDType`

`numpy.dtypes.ULongLongDType`

Floating point

`numpy.dtypes.Float16DType`

`numpy.dtypes.Float32DType`

`numpy.dtypes.Float64DType`

`numpy.dtypes.LongDoubleDType`

Complex

`numpy.dtypes.Complex64DType`

`numpy.dtypes.Complex128DType`

`numpy.dtypes.CLongDoubleDType`

Strings and Bytestrings

`numpy.dtypes.StrDType`
`numpy.dtypes.BytesDType`
`numpy.dtypes.StringDType`

Times

`numpy.dtypes.DateTime64DType`
`numpy.dtypes.TimeDelta64DType`

Others

`numpy.dtypes.ObjectDType`
`numpy.dtypes.VoidDType`

Routines for DType authors

<code>register_dlpack_dtype(dlpack_key, dtype, /)</code>	Register a NumPy dtype for a DLPack (code, bits) pair so that <code>numpy.from_dlpack</code> can import it and <code>ndarray.__dlpack__</code> can export it.
--	---

`dtypes.register_dlpack_dtype(dlpack_key, dtype, /)`

Register a NumPy dtype for a DLPack (code, bits) pair so that `numpy.from_dlpack` can import it and `ndarray.__dlpack__` can export it. Built-in dtype mappings take priority on import.

If you think a conflict is possible but unproblematic you may wrap this into a try/except block as NumPy will raise an error if another DType is already registered for the same (code, bits) pair. While an error is raised, the export is registered even on error.

Registering an identical (not equal) dtype multiple times is allowed but normally registration should happen at import time.

Warning: It is the responsibility of the registering user to ensure that the mapping is valid.

Note: This function was added primarily for `ml_dtypes` and may be replaced with a different mechanism in the future. It is intended to be used by authors of user-defined dtypes and not end-users.

Parameters

dlpack_key

[tuple of int] (dl_dtype_code, dl_bits) matching the DLPack `DLDataType`, lanes is assumed to be always 1, currently.

dtype

[dtype] A NumPy dtype instance.

Raises

ValueError

[If a conflicting registration was already done.]

See also:

numpy.from_dlpack

Mathematical functions with automatic domain

Note: `numpy.emath` is a preferred alias for `numpy.lib.scimath`, available after `numpy` is imported.

Wrapper functions to more user-friendly calling of certain math functions whose output data-type is different than the input data-type in certain domains of the input.

For example, for functions like `log` with branch cuts, the versions in this module provide the mathematically valid answers in the complex plane:

```
>>> import numpy as np
>>> import math
>>> np.emath.log(-math.exp(1)) == (1+1j*math.pi)
True
```

Similarly, `sqrt`, other base logarithms, `power` and trig functions are correctly handled. See their respective docstrings for specific examples.

Functions

<code>arccos(x)</code>	Compute the inverse cosine of x .
<code>arcsin(x)</code>	Compute the inverse sine of x .
<code>arctanh(x)</code>	Compute the inverse hyperbolic tangent of x .
<code>log(x)</code>	Compute the natural logarithm of x .
<code>log2(x)</code>	Compute the logarithm base 2 of x .
<code>logn(n, x)</code>	Take log base n of x .
<code>log10(x)</code>	Compute the logarithm base 10 of x .
<code>power(x, p)</code>	Return x to the power p , $(x**p)$.
<code>sqrt(x)</code>	Compute the square root of x .

`emath.arccos(x)`

Compute the inverse cosine of x .

Return the “principal value” (for a description of this, see [`numpy.arccos`](#)) of the inverse cosine of x . For real x such that $abs(x) \leq 1$, this is a real number in the closed interval $[0, \pi]$. Otherwise, the complex principle value is returned.

Parameters

x

[array_like or scalar] The value(s) whose arccos is (are) required.

Returns

out

[ndarray or scalar] The inverse cosine(s) of the x value(s). If x was a scalar, so is *out*, otherwise an array object is returned.

See also:

[`numpy.arccos`](#)

Notes

For an `arccos()` that returns `NAN` when real x is not in the interval $[-1, 1]$, use `numpy.arccos`.

Examples

```
>>> import numpy as np
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.arccos(1) # a scalar is returned
0.0
```

```
>>> np.emath.arccos([1, 2])
array([0.-0.j      , 0.-1.317j])
```

`emath.arcsin(x)`

Compute the inverse sine of x .

Return the “principal value” (for a description of this, see `numpy.arcsin`) of the inverse sine of x . For real x such that $abs(x) \leq 1$, this is a real number in the closed interval $[-\pi/2, \pi/2]$. Otherwise, the complex principle value is returned.

Parameters

x

[array_like or scalar] The value(s) whose arcsin is (are) required.

Returns

out

[ndarray or scalar] The inverse sine(s) of the x value(s). If x was a scalar, so is *out*, otherwise an array object is returned.

See also:

`numpy.arcsin`

Notes

For an `arcsin()` that returns `NAN` when real x is not in the interval $[-1, 1]$, use `numpy.arcsin`.

Examples

```
>>> import numpy as np
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.arcsin(0)
0.0
```

```
>>> np.emath.arcsin([0, 1])
array([0.      , 1.5708])
```

`emath.arctanh(x)`

Compute the inverse hyperbolic tangent of x .

Return the “principal value” (for a description of this, see [numpy.arctanh](#)) of `arctanh(x)`. For real x such that $\text{abs}(x) < 1$, this is a real number. If $\text{abs}(x) > 1$, or if x is complex, the result is complex. Finally, $x = 1$ returns `inf` and $x = -1$ returns `-inf`.

Parameters

x

[array_like] The value(s) whose arctanh is (are) required.

Returns

out

[ndarray or scalar] The inverse hyperbolic tangent(s) of the x value(s). If x was a scalar so is *out*, otherwise an array is returned.

See also:

[numpy.arctanh](#)

Notes

For an `arctanh()` that returns `NAN` when real x is not in the interval $(-1, 1)$, use [numpy.arctanh](#) (this latter, however, does return $\pm\text{inf}$ for $x = \pm 1$).

Examples

```
>>> import numpy as np
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.arctanh(0.5)
0.5493061443340549
```

```
>>> import warnings
>>> with warnings.catch_warnings():
...     warnings.simplefilter('ignore', RuntimeWarning)
...     np.emath.arctanh(np.eye(2))
array([[inf,  0.],
       [ 0., inf]])
>>> np.emath.arctanh([1j])
array([0.+0.7854j])
```

`emath.log(x)`

Compute the natural logarithm of x .

Return the “principal value” (for a description of this, see [numpy.log](#)) of $\log_e(x)$. For real $x > 0$, this is a real number (`log(0)` returns `-inf` and `log(np.inf)` returns `inf`). Otherwise, the complex principle value is returned.

Parameters

x

[array_like] The value(s) whose log is (are) required.

Returns

out

[ndarray or scalar] The log of the x value(s). If x was a scalar, so is *out*, otherwise an array is returned.

See also:

[`numpy.log`](#)

Notes

For a `log()` that returns NAN when real $x < 0$, use [`numpy.log`](#) (note, however, that otherwise [`numpy.log`](#) and this `log` are identical, i.e., both return $-\infty$ for $x = 0$, ∞ for $x = \infty$, and, notably, the complex principle value if $x.\text{imag} \neq 0$).

Examples

```
>>> import numpy as np
>>> np.emath.log(np.exp(1))
1.0
```

Negative arguments are handled “correctly” (recall that $\exp(\log(x)) == x$ does *not* hold for real $x < 0$):

```
>>> np.emath.log(-np.exp(1)) == (1 + np.pi * 1j)
True
```

`emath.log2( $x$ )`

Compute the logarithm base 2 of x .

Return the “principal value” (for a description of this, see [`numpy.log2`](#)) of $\log_2(x)$. For real $x > 0$, this is a real number (`log2(0)` returns $-\infty$ and `log2(np.inf)` returns ∞). Otherwise, the complex principle value is returned.

Parameters

x

[array_like] The value(s) whose log base 2 is (are) required.

Returns

out

[ndarray or scalar] The log base 2 of the x value(s). If x was a scalar, so is *out*, otherwise an array is returned.

See also:

[`numpy.log2`](#)

Notes

For a `log2()` that returns `NAN` when real $x < 0$, use `numpy.log2` (note, however, that otherwise `numpy.log2` and this `log2` are identical, i.e., both return `-inf` for $x = 0$, `inf` for $x = inf$, and, notably, the complex principle value if $x.\text{imag} \neq 0$).

Examples

We set the printing precision so the example can be auto-tested:

```
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.log2(8)
3.0
>>> np.emath.log2([-4, -8, 8])
array([2.+4.5324j, 3.+4.5324j, 3.+0.j      ])
```

`emath.logn(n, x)`

Take log base *n* of *x*.

If *x* contains negative inputs, the answer is computed and returned in the complex domain.

Parameters

n

[array_like] The integer base(s) in which the log is taken.

x

[array_like] The value(s) whose log base *n* is (are) required.

Returns

out

[ndarray or scalar] The log base *n* of the *x* value(s). If *x* was a scalar, so is *out*, otherwise an array is returned.

Examples

```
>>> import numpy as np
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.logn(2, [4, 8])
array([2., 3.])
>>> np.emath.logn(2, [-4, -8, 8])
array([2.+4.5324j, 3.+4.5324j, 3.+0.j      ])
```

`emath.log10(x)`

Compute the logarithm base 10 of *x*.

Return the “principal value” (for a description of this, see `numpy.log10`) of $\log_{10}(x)$. For real $x > 0$, this is a real number (`log10(0)` returns `-inf` and `log10(np.inf)` returns `inf`). Otherwise, the complex principle value is returned.

Parameters

x

[array_like or scalar] The value(s) whose log base 10 is (are) required.

Returns**out**

[ndarray or scalar] The log base 10 of the x value(s). If x was a scalar, so is *out*, otherwise an array object is returned.

See also:[`numpy.log10`](#)**Notes**

For a `log10()` that returns `NAN` when real $x < 0$, use [`numpy.log10`](#) (note, however, that otherwise [`numpy.log10`](#) and this `log10` are identical, i.e., both return $-\infty$ for $x = 0$, ∞ for $x = \infty$, and, notably, the complex principle value if $x.\text{imag} \neq 0$).

Examples

```
>>> import numpy as np
```

(We set the printing precision so the example can be auto-tested)

```
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.log10(10**1)
1.0
```

```
>>> np.emath.log10([-10**1, -10**2, 10**2])
array([1.+1.3644j, 2.+1.3644j, 2.+0.j      ])
```

`emath.power` (x, p)

Return x to the power p , ($x**p$).

If x contains negative values, the output is converted to the complex domain.

Parameters**x**

[array_like] The input value(s).

p

[array_like of ints] The power(s) to which x is raised. If x contains multiple values, p has to either be a scalar, or contain the same number of values as x . In the latter case, the result is $x[0]**p[0]$, $x[1]**p[1]$,

Returns**out**

[ndarray or scalar] The result of $x**p$. If x and p are scalars, so is *out*, otherwise an array is returned.

See also:[`numpy.power`](#)

Examples

```
>>> import numpy as np
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.power(2, 2)
4
```

```
>>> np.emath.power([2, 4], 2)
array([ 4, 16])
```

```
>>> np.emath.power([2, 4], -2)
array([0.25 ,  0.0625])
```

```
>>> np.emath.power([-2, 4], 2)
array([ 4.-0.j, 16.+0.j])
```

```
>>> np.emath.power([2, 4], [2, 4])
array([ 4, 256])
```

`emath.sqrt(x)`

Compute the square root of `x`.

For negative input elements, a complex value is returned (unlike `numpy.sqrt` which returns NaN).

Parameters

x
[array_like] The input value(s).

Returns

out
[ndarray or scalar] The square root of `x`. If `x` was a scalar, so is `out`, otherwise an array is returned.

See also:

`numpy.sqrt`

Examples

For real, non-negative inputs this works just like `numpy.sqrt`:

```
>>> import numpy as np
```

```
>>> np.emath.sqrt(1)
1.0
>>> np.emath.sqrt([1, 4])
array([1.,  2.])
```

But it automatically handles negative inputs:

```
>>> np.emath.sqrt(-1)
1j
>>> np.emath.sqrt([-1, 4])
array([0.+1.j, 2.+0.j])
```

Different results are expected because: floating point 0.0 and -0.0 are distinct.

For more control, explicitly use `complex()` as follows:

```
>>> np.emath.sqrt(complex(-4.0, 0.0))
2j
>>> np.emath.sqrt(complex(-4.0, -0.0))
-2j
```

Lib module (`numpy.lib`)

Functions & other objects

<code>add_docstring(obj, docstring)</code>	Add a docstring to a built-in obj if possible.
<code>add_newdoc(place, obj, doc[, warn_on_python])</code>	Add documentation to an existing object, typically one defined in C
<code>Arrayiterator(var[, buf_size])</code>	Buffered iterator for big arrays.
<code>NumpyVersion(vstring)</code>	Parse and compare numpy version strings.

`lib.add_docstring(obj, docstring)`

Add a docstring to a built-in obj if possible. If the obj already has a docstring raise a `RuntimeError` If this routine does not know how to add a docstring to the object raise a `TypeError`

`lib.add_newdoc(place, obj, doc, warn_on_python=True)`

Add documentation to an existing object, typically one defined in C

The purpose is to allow easier editing of the docstrings without requiring a re-compile. This exists primarily for internal use within numpy itself.

Parameters

place

[str] The absolute name of the module to import from

obj

[str | None] The name of the object to add documentation to, typically a class or function name.

doc

[str | tuple[str, str] | list[tuple[str, str]]] If a string, the documentation to apply to *obj*

If a tuple, then the first element is interpreted as an attribute of *obj* and the second as the docstring to apply - (method, docstring)

If a list, then each element of the list should be a tuple of length two - [(method1, docstring1), (method2, docstring2), ...]

warn_on_python

[bool] If True, the default, emit *UserWarning* if this is used to attach documentation to a pure-python object.

Notes

This routine never raises an error if the docstring can't be written, but will raise an error if the object being documented does not exist.

This routine cannot modify read-only docstrings, as appear in new-style classes or built-in functions. Because this routine never raises an error the caller must check manually that the docstrings were changed.

Since this function grabs the `char *` from a c-level str object and puts it into the `tp_doc` slot of the type of *obj*, it violates a number of C-API best-practices, by:

- modifying a *PyTypeObject* after calling *PyType_Ready*
- calling *Py_INCREF* on the str and losing the reference, so the str will never be released

If possible it should be avoided.

class `numpy.lib.Arrayiterator` (*var*, *buf_size=None*)

Buffered iterator for big arrays.

Arrayiterator creates a buffered iterator for reading big arrays in small contiguous blocks. The class is useful for objects stored in the file system. It allows iteration over the object *without* reading everything in memory; instead, small blocks are read and iterated over.

Arrayiterator can be used with any object that supports multidimensional slices. This includes NumPy arrays, but also variables from Scientific.IO.NetCDF or pynetcdf for example.

Parameters

var

[array_like] The object to iterate over.

buf_size

[int, optional] The buffer size. If *buf_size* is supplied, the maximum amount of data that will be read into memory is *buf_size* elements. Default is None, which will read as many element as possible into memory.

Attributes

var

buf_size

start

stop

step

shape

The shape of the array to be iterated over.

flat

A 1-D flat iterator for Arrayiterator objects.

See also:

numpy.ndenumerate

Multidimensional array iterator.

numpy.flatiter

Flat array iterator.

numpy.memmap

Create a memory-map to an array stored in a binary file on disk.

Notes

The algorithm works by first finding a “running dimension”, along which the blocks will be extracted. Given an array of dimensions $(d_1, d_2, \dots, d_n)$, e.g. if *buf_size* is smaller than d_1 , the first dimension will be used. If, on the other hand, $d_1 < \text{buf_size} < d_1 * d_2$ the second dimension will be used, and so on. Blocks are extracted along this dimension, and when the last block is returned the process continues from the next dimension, until all elements have been read.

Examples

```
>>> import numpy as np
>>> a = np.arange(3 * 4 * 5 * 6).reshape(3, 4, 5, 6)
>>> a_itor = np.lib.Arrayiterator(a, 2)
>>> a_itor.shape
(3, 4, 5, 6)
```

Now we can iterate over *a_itor*, and it will return arrays of size two. Since *buf_size* was smaller than any dimension, the first dimension will be iterated over first:

```
>>> for subarr in a_itor:
...     if not subarr.all():
...         print(subarr, subarr.shape)
>>> # [[[[0 1]]]] (1, 1, 1, 2)
```

class `numpy.lib.NumpyVersion` (*vstring*)

Parse and compare numpy version strings.

NumPy has the following versioning scheme (numbers given are examples; they can be > 9 in principle):

- Released version: ‘1.8.0’, ‘1.8.1’, etc.
- Alpha: ‘1.8.0a1’, ‘1.8.0a2’, etc.
- Beta: ‘1.8.0b1’, ‘1.8.0b2’, etc.
- Release candidates: ‘1.8.0rc1’, ‘1.8.0rc2’, etc.
- Development versions: ‘1.8.0.dev-f1234afa’ (git commit hash appended)
- Development versions after a1: ‘1.8.0a1.dev-f1234afa’, ‘1.8.0b2.dev-f1234afa’, ‘1.8.1rc1.dev-f1234afa’, etc.
- Development versions (no git hash available): ‘1.8.0.dev-Unknown’

Comparing needs to be done against a valid version string or other *NumpyVersion* instance. Note that all development versions of the same (pre-)release compare equal.

Parameters

vstring

[str] NumPy version string (`np.__version__`).

Examples

```
>>> from numpy.lib import NumpyVersion
>>> if NumpyVersion(np.__version__) < '1.7.0':
...     print('skip')
>>> # skip
```

```
>>> NumpyVersion('1.7') # raises ValueError, add ".0"
Traceback (most recent call last):
...
ValueError: Not a valid numpy version string
```

Submodules

<code>array_utils</code>	Miscellaneous utils.
<code>format</code>	Binary serialization
<code>introspect</code>	Introspection helper functions.
<code>mixins</code>	Mixin classes for custom array types that don't inherit from ndarray.
<code>npymath</code>	IO related functions.
<code>scimath</code>	Wrapper functions to more user-friendly calling of certain math functions whose output data-type is different than the input data-type in certain domains of the input.
<code>stride_tricks</code>	Utilities that manipulate strides to achieve desirable effects.

Miscellaneous utils.

Functions

<code>byte_bounds(a)</code>	Returns pointers to the end-points of an array.
<code>normalize_axis_index(axis, ndim[, msg_prefix])</code>	Normalizes an axis index, <i>axis</i> , such that is a valid positive index into the shape of array with <i>ndim</i> dimensions.
<code>normalize_axis_tuple(axis, ndim[, argname, ...])</code>	Normalizes an axis argument into a tuple of non-negative integer axes.

`lib.array_utils.byte_bounds(a)`

Returns pointers to the end-points of an array.

Parameters

a

[ndarray] Input array. It must conform to the Python-side of the array interface.

Returns

(low, high)

[tuple of 2 integers] The first integer is the first byte of the array, the second integer is just past the last byte of the array. If *a* is not contiguous it will not use every byte between the (*low*, *high*) values.

Examples

```
>>> import numpy as np
>>> I = np.eye(2, dtype=np.float32); I.dtype
dtype('float32')
>>> low, high = np.lib.array_utils.byte_bounds(I)
>>> high - low == I.size*I.itemsize
True
>>> I = np.eye(2); I.dtype
dtype('float64')
>>> low, high = np.lib.array_utils.byte_bounds(I)
>>> high - low == I.size*I.itemsize
True
```

`lib.array_utils.normalize_axis_index` (*axis*, *ndim*, *msg_prefix=None*)

Normalizes an axis index, *axis*, such that is a valid positive index into the shape of array with *ndim* dimensions. Raises an `AxisError` with an appropriate message if this is not possible.

Used internally by all axis-checking logic.

Parameters

axis

[int] The un-normalized index of the axis. Can be negative

ndim

[int] The number of dimensions of the array that *axis* should be normalized against

msg_prefix

[str] A prefix to put before the message, typically the name of the argument

Returns

normalized_axis

[int] The normalized axis index, such that $0 \leq \text{normalized_axis} < \text{ndim}$

Raises

AxisError

If the axis index is invalid, when $-\text{ndim} \leq \text{axis} < \text{ndim}$ is false.

Examples

```
>>> import numpy as np
>>> from numpy.lib.array_utils import normalize_axis_index
>>> normalize_axis_index(0, ndim=3)
0
>>> normalize_axis_index(1, ndim=3)
1
>>> normalize_axis_index(-1, ndim=3)
2
```

```
>>> normalize_axis_index(3, ndim=3)
Traceback (most recent call last):
...
numpy.exceptions.AxisError: axis 3 is out of bounds for array ...
>>> normalize_axis_index(-4, ndim=3, msg_prefix='axes_arg')
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
numpy.exceptions.AxisError: axes_arg: axis -4 is out of bounds ...
```

`lib.array_utils.normalize_axis_tuple` (*axis*, *ndim*, *argname=None*, *allow_duplicate=False*)

Normalizes an axis argument into a tuple of non-negative integer axes.

This handles shorthands such as 1 and converts them to (1,), as well as performing the handling of negative indices covered by [normalize_axis_index](#).

By default, this forbids axes from being specified multiple times.

Used internally by multi-axis-checking logic.

Parameters

axis

[int, iterable of int] The un-normalized index or indices of the axis.

ndim

[int] The number of dimensions of the array that *axis* should be normalized against.

argname

[str, optional] A prefix to put before the error message, typically the name of the argument.

allow_duplicate

[bool, optional] If False, the default, disallow an axis from being specified twice.

Returns

normalized_axes

[tuple of int] The normalized axis index, such that $0 \leq \text{normalized_axis} < \text{ndim}$

Raises

AxisError

If any axis provided is out of range

ValueError

If an axis is repeated

[normalize_axis_index](#)

normalizing a single scalar axis

Binary serialization

NPY format

A simple format for saving numpy arrays to disk with the full information about them.

The `.npy` format is the standard binary file format in NumPy for persisting a *single* arbitrary NumPy array on disk. The format stores all of the shape and dtype information necessary to reconstruct the array correctly even on another machine with a different architecture. The format is designed to be as simple as possible while achieving its limited goals.

The `.npz` format is the standard format for persisting *multiple* NumPy arrays on disk. A `.npz` file is a zip file containing multiple `.npy` files, one for each array.

Capabilities

- Can represent all NumPy arrays including nested record arrays and object arrays.
- Represents the data in its native binary form.
- Supports Fortran-contiguous arrays directly.
- Stores all of the necessary information to reconstruct the array including shape and dtype on a machine of a different architecture. Both little-endian and big-endian arrays are supported, and a file with little-endian numbers will yield a little-endian array on any machine reading the file. The types are described in terms of their actual sizes. For example, if a machine with a 64-bit C “long int” writes out an array with “long ints”, a reading machine with 32-bit C “long ints” will yield an array with 64-bit integers.
- Is straightforward to reverse engineer. Datasets often live longer than the programs that created them. A competent developer should be able to create a solution in their preferred programming language to read most `.npy` files that they have been given without much documentation.
- Allows memory-mapping of the data. See [`open\_mmap`](#).
- Can be read from a filelike stream object instead of an actual file.
- Stores object arrays, i.e. arrays containing elements that are arbitrary Python objects. Files with object arrays are not to be mmapable, but can be read and written to disk.

Limitations

- Arbitrary subclasses of `numpy.ndarray` are not completely preserved. Subclasses will be accepted for writing, but only the array data will be written out. A regular `numpy.ndarray` object will be created upon reading the file.

Warning: Due to limitations in the interpretation of structured dtypes, dtypes with fields with empty names will have the names replaced by ‘f0’, ‘f1’, etc. Such arrays will not round-trip through the format entirely accurately. The data is intact; only the field names will differ. We are working on a fix for this. This fix will not require a change in the file format. The arrays with such structures can still be saved and restored, and the correct dtype may be restored by using the `loadedarray.view(correct_dtype)` method.

File extensions

We recommend using the `.npy` and `.npz` extensions for files saved in this format. This is by no means a requirement; applications may wish to use these file formats but use an extension specific to the application. In the absence of an obvious alternative, however, we suggest using `.npy` and `.npz`.

Version numbering

The version numbering of these formats is independent of NumPy version numbering. If the format is upgraded, the code in `numpy.io` will still be able to read and write Version 1.0 files.

Format Version 1.0

The first 6 bytes are a magic string: exactly `\x93NUMPY`.

The next 1 byte is an unsigned byte: the major version number of the file format, e.g. `\x01`.

The next 1 byte is an unsigned byte: the minor version number of the file format, e.g. `\x00`. Note: the version of the file format is not tied to the version of the numpy package.

The next 2 bytes form a little-endian unsigned short int: the length of the header data `HEADER_LEN`.

The next `HEADER_LEN` bytes form the header data describing the array's format. It is an ASCII string which contains a Python literal expression of a dictionary. It is terminated by a newline (`\n`) and padded with spaces (`\x20`) to make the total of `len(magic string) + 2 + len(length) + HEADER_LEN` be evenly divisible by 64 for alignment purposes.

The dictionary contains three keys:

“descr”

[dtype.descr] An object that can be passed as an argument to the `numpy.dtype` constructor to create the array's dtype.

“fortran_order”

[bool] Whether the array data is Fortran-contiguous or not. Since Fortran-contiguous arrays are a common form of non-C-contiguity, we allow them to be written directly to disk for efficiency.

“shape”

[tuple of int] The shape of the array.

For repeatability and readability, the dictionary keys are sorted in alphabetic order. This is for convenience only. A writer SHOULD implement this if possible. A reader MUST NOT depend on this.

Following the header comes the array data. If the dtype contains Python objects (i.e. `dtype.hasobject` is `True`), then the data is a Python pickle of the array. Otherwise the data is the contiguous (either C- or Fortran-, depending on `fortran_order`) bytes of the array. Consumers can figure out the number of bytes by multiplying the number of elements given by the shape (noting that `shape=()` means there is 1 element) by `dtype.itemsize`.

Format Version 2.0

The version 1.0 format only allowed the array header to have a total size of 65535 bytes. This can be exceeded by structured arrays with a large number of columns. The version 2.0 format extends the header size to 4 GiB. `numpy.save` will automatically save in 2.0 format if the data requires it, else it will always use the more compatible 1.0 format.

The description of the fourth element of the header therefore has become: “The next 4 bytes form a little-endian unsigned int: the length of the header data `HEADER_LEN`.”

Format Version 3.0

This version replaces the ASCII string (which in practice was latin1) with a utf8-encoded string, so supports structured types with any unicode field names.

Notes

The `.npy` format, including motivation for creating it and a comparison of alternatives, is described in the “[npv-format](#)” NEP, however details have evolved with time and this document is more current.

Functions

<code>descr_to_dtype(descr)</code>	Returns a dtype based off the given description.
<code>drop_metadata(dtype, /)</code>	Returns the dtype unchanged if it contained no metadata or a copy of the dtype if it (or any of its structure dtypes) contained metadata.
<code>dtype_to_descr(dtype)</code>	Get a serializable descriptor from the dtype.
<code>header_data_from_array_1_0(array)</code>	Get the dictionary of header metadata from a <code>numpy.ndarray</code> .
<code>isfileobj(f)</code>	
<code>magic(major, minor)</code>	Return the magic string for the given file format version.
<code>open_memmap(filename[, mode, dtype, shape, ...])</code>	Open a <code>.npy</code> file as a memory-mapped array.
<code>read_array(fp[, allow_pickle, ...])</code>	Read an array from an NPY file.
<code>read_array_header_1_0(fp[, max_header_size])</code>	Read an array header from a filelike object using the 1.0 file format version.
<code>read_array_header_2_0(fp[, max_header_size])</code>	Read an array header from a filelike object using the 2.0 file format version.
<code>read_magic(fp)</code>	Read the magic string to get the version of the file format.
<code>write_array(fp, array[, version, ...])</code>	Write an array to an NPY file, including a header.
<code>write_array_header_1_0(fp, d)</code>	Write the header for an array using the 1.0 format.
<code>write_array_header_2_0(fp, d)</code>	Write the header for an array using the 2.0 format.

`lib.format.descr_to_dtype(descr)`

Returns a dtype based off the given description.

This is essentially the reverse of `dtype_to_descr`. It will remove the valueless padding fields created by, i.e. simple fields like `dtype('float32')`, and then convert the description to its corresponding dtype.

Parameters

`descr`

[object] The object retrieved by `dtype.descr`. Can be passed to `numpy.dtype` in order to replicate the input dtype.

Returns

`dtype`

[dtype] The dtype constructed by the description.

`lib.format.drop_metadata(dtype, /)`

Returns the dtype unchanged if it contained no metadata or a copy of the dtype if it (or any of its structure dtypes) contained metadata.

This utility is used by `np.save` and `np.savez` to drop metadata before saving.

Note: Due to its limitation this function may move to a more appropriate home or change in the future and is considered semi-public API only.

Warning: This function does not preserve more strange things like record dtypes and user dtypes may simply return the wrong thing. If you need to be sure about the latter, check the result with: `np.can_cast(new_dtype, dtype, casting="no")`.

`lib.format.dtype_to_descr(dtype)`

Get a serializable descriptor from the dtype.

The `.descr` attribute of a dtype object cannot be round-tripped through the `dtype()` constructor. Simple types, like `dtype('float32')`, have a `descr` which looks like a record array with one field with `"` as a name. The `dtype()` constructor interprets this as a request to give a default name. Instead, we construct descriptor that can be passed to `dtype()`.

Parameters

dtype

[dtype] The dtype of the array that will be written to disk.

Returns

descr

[object] An object that can be passed to `numpy.dtype()` in order to replicate the input dtype.

`lib.format.header_data_from_array_1_0(array)`

Get the dictionary of header metadata from a `numpy.ndarray`.

Parameters

array

[numpy.ndarray]

Returns

d

[dict] This has the appropriate entries for writing its string representation to the header of the file.

`lib.format.isfileobj(f)`

`lib.format.magic(major, minor)`

Return the magic string for the given file format version.

Parameters

major

[int in [0, 255]]

minor

[int in [0, 255]]

Returns

magic

[str]

Raises

ValueError if the version cannot be formatted.

`lib.format.open_memmap(filename, mode='r+', dtype=None, shape=None, fortran_order=False, version=None, *, max_header_size=10000)`

Open a .npy file as a memory-mapped array.

This may be used to read an existing file or create a new one.

Parameters

filename

[str or path-like] The name of the file on disk. This may *not* be a file-like object.

mode

[str, optional] The mode in which to open the file; the default is 'r+'. In addition to the standard file modes, 'c' is also accepted to mean “copy on write.” See [memmap](#) for the available mode strings.

dtype

[data-type, optional] The data type of the array if we are creating a new file in “write” mode, if not, [dtype](#) is ignored. The default value is None, which results in a data-type of [float64](#).

shape

[tuple of int] The shape of the array if we are creating a new file in “write” mode, in which case this parameter is required. Otherwise, this parameter is ignored and is thus optional.

fortran_order

[bool, optional] Whether the array should be Fortran-contiguous (True) or C-contiguous (False, the default) if we are creating a new file in “write” mode.

version

[tuple of int (major, minor) or None] If the mode is a “write” mode, then this is the version of the file format used to create the file. None means use the oldest supported version that is able to store the data. Default: None

max_header_size

[int, optional] Maximum allowed size of the header. Large headers may not be safe to load securely and thus require explicitly passing a larger value. See [ast.literal_eval](#) for details.

Returns

marray

[memmap] The memory-mapped array.

Raises

ValueError

If the data or the mode is invalid.

OSError

If the file is not found or cannot be opened correctly.

See also:

[numpy.memmap](#)

```
lib.format.read_array(fp, allow_pickle=False, pickle_kwargs=None, *, max_header_size=10000)
```

Read an array from an NPY file.

Parameters

fp

[file_like object] If this is not a real file object, then this may take extra memory and time.

allow_pickle

[bool, optional] Whether to allow writing pickled data. Default: False

pickle_kwargs

[dict] Additional keyword arguments to pass to pickle.load. These are only useful when loading object arrays saved on Python 2.

max_header_size

[int, optional] Maximum allowed size of the header. Large headers may not be safe to load securely and thus require explicitly passing a larger value. See `ast.literal_eval` for details. This option is ignored when `allow_pickle` is passed. In that case the file is by definition trusted and the limit is unnecessary.

Returns**array**

[ndarray] The array from the data on disk.

Raises**ValueError**

If the data is invalid, or `allow_pickle=False` and the file contains an object array.

`lib.format.read_array_header_1_0(fp, max_header_size=10000)`

Read an array header from a filelike object using the 1.0 file format version.

This will leave the file object located just after the header.

Parameters**fp**

[filelike object] A file object or something with a `read()` method like a file.

Returns**shape**

[tuple of int] The shape of the array.

fortran_order

[bool] The array data will be written out directly if it is either C-contiguous or Fortran-contiguous. Otherwise, it will be made contiguous before writing it out.

dtype

[dtype] The dtype of the file's data.

max_header_size

[int, optional] Maximum allowed size of the header. Large headers may not be safe to load securely and thus require explicitly passing a larger value. See `ast.literal_eval` for details.

Raises**ValueError**

If the data is invalid.

`lib.format.read_array_header_2_0(fp, max_header_size=10000)`

Read an array header from a filelike object using the 2.0 file format version.

This will leave the file object located just after the header.

Parameters**fp**

[filelike object] A file object or something with a `read()` method like a file.

max_header_size

[int, optional] Maximum allowed size of the header. Large headers may not be safe to load securely and thus require explicitly passing a larger value. See `ast.literal_eval` for details.

Returns**shape**

[tuple of int] The shape of the array.

fortran_order

[bool] The array data will be written out directly if it is either C-contiguous or Fortran-contiguous. Otherwise, it will be made contiguous before writing it out.

dtype

[dtype] The dtype of the file's data.

Raises**ValueError**

If the data is invalid.

`lib.format.read_magic(fp)`

Read the magic string to get the version of the file format.

Parameters**fp**

[filelike object]

Returns**major**

[int]

minor

[int]

`lib.format.write_array(fp, array, version=None, allow_pickle=True, pickle_kwargs=None)`

Write an array to an NPY file, including a header.

If the array is neither C-contiguous nor Fortran-contiguous AND the file_like object is not a real file object, this function will have to copy data in memory.

Parameters**fp**

[file_like object] An open, writable file object, or similar object with a `.write()` method.

array

[ndarray] The array to write to disk.

version

[(int, int) or None, optional] The version number of the format. None means use the oldest supported version that is able to store the data. Default: None

allow_pickle

[bool, optional] Whether to allow writing pickled data. Default: True

pickle_kwargs

[dict, optional] Additional keyword arguments to pass to `pickle.dump`, excluding 'protocol'. These are only useful when pickling objects in object arrays to Python 2 compatible format.

Raises

ValueError

If the array cannot be persisted. This includes the case of `allow_pickle=False` and array being an object array.

Various other errors

If the array contains Python objects as part of its dtype, the process of pickling them may raise various errors if the objects are not picklable.

```
lib.format.write_array_header_1_0(fp, d)
```

Write the header for an array using the 1.0 format.

Parameters**fp**

[filelike object]

d

[dict] This has the appropriate entries for writing its string representation to the header of the file.

```
lib.format.write_array_header_2_0(fp, d)
```

Write the header for an array using the 2.0 format.

The 2.0 format allows storing very large structured arrays.

Parameters**fp**

[filelike object]

d

[dict] This has the appropriate entries for writing its string representation to the header of the file.

Introspection helper functions.

Functions

```
opt_func_info([func_name, signature])
```

Returns a dictionary containing the currently supported CPU dispatched features for all optimized functions.

```
lib.introspect.opt_func_info(func_name=None, signature=None)
```

Returns a dictionary containing the currently supported CPU dispatched features for all optimized functions.

Parameters**func_name**

[str (optional)] Regular expression to filter by function name.

signature

[str (optional)] Regular expression to filter by data type.

Returns**dict**

A dictionary where keys are optimized function names and values are nested dictionaries indicating supported targets based on data types.

Examples

Retrieve dispatch information for functions named ‘add’ or ‘sub’ and data types ‘float64’ or ‘float32’:

```
>>> import numpy as np
>>> dict = np.lib.introspect.opt_func_info(
...     func_name="add|abs", signature="float64|complex64"
... )
>>> import json
>>> print(json.dumps(dict, indent=2))    # may vary (architecture)
{
  "absolute": {
    "dd": {
      "current": "SSE41",
      "available": "SSE41 baseline(SSE SSE2 SSE3)"
    },
    "Ff": {

      "available": "AVX512F FMA3__AVX2 baseline(SSE SSE2 SSE3)"
    },
    "Dd": {
      "current": "FMA3__AVX2",
      "available": "AVX512F FMA3__AVX2 baseline(SSE SSE2 SSE3)"
    }
  },
  "add": {
    "ddd": {
      "current": "FMA3__AVX2",
      "available": "FMA3__AVX2 baseline(SSE SSE2 SSE3)"
    },
    "FFF": {
      "current": "FMA3__AVX2",
      "available": "FMA3__AVX2 baseline(SSE SSE2 SSE3)"
    }
  }
}
```

Mixin classes for custom array types that don’t inherit from ndarray.

Classes

`NDArrayOperatorsMixin()`

Mixin defining all operator special methods using `__array_ufunc__`.

class `numpy.lib.mixins.NDArrayOperatorsMixin`

Mixin defining all operator special methods using `__array_ufunc__`.

This class implements the special methods for almost all of Python’s builtin operators defined in the `operator` module, including comparisons (`==`, `>`, etc.) and arithmetic (`+`, `*`, `-`, etc.), by deferring to the `__array_ufunc__` method, which subclasses must implement.

It is useful for writing classes that do not inherit from `numpy.ndarray`, but that should support arithmetic and numpy universal functions like arrays as described in [NEP 13 — A mechanism for overriding Ufuncs](#).

As a trivial example, consider this implementation of an `ArrayLike` class that simply wraps a NumPy array and ensures that the result of any arithmetic operation is also an `ArrayLike` object:

```

>>> import numbers
>>> class ArrayLike(np.lib.mixins.NDArrayOperatorsMixin):
...     def __init__(self, value):
...         self.value = np.asarray(value)
...
...     # One might also consider adding the built-in list type to this
...     # list, to support operations like np.add(array_like, list)
...     _HANDLED_TYPES = (np.ndarray, numbers.Number)
...
...     def __array_ufunc__(self, ufunc, method, *inputs, **kwargs):
...         out = kwargs.get('out', ())
...         for x in inputs + out:
...             # Only support operations with instances of
...             # _HANDLED_TYPES. Use ArrayLike instead of type(self)
...             # for isinstance to allow subclasses that don't
...             # override __array_ufunc__ to handle ArrayLike objects.
...             if not isinstance(
...                 x, self._HANDLED_TYPES + (ArrayLike,)
...             ):
...                 return NotImplemented
...
...         # Defer to the implementation of the ufunc
...         # on unwrapped values.
...         inputs = tuple(x.value if isinstance(x, ArrayLike) else x
...                        for x in inputs)
...         if out:
...             kwargs['out'] = tuple(
...                 x.value if isinstance(x, ArrayLike) else x
...                 for x in out)
...         result = getattr(ufunc, method)(*inputs, **kwargs)
...
...         if type(result) is tuple:
...             # multiple return values
...             return tuple(type(self)(x) for x in result)
...         elif method == 'at':
...             # no return value
...             return None
...         else:
...             # one return value
...             return type(self)(result)
...
...     def __repr__(self):
...         return '%s(%r)' % (type(self).__name__, self.value)

```

In interactions between ArrayLike objects and numbers or numpy arrays, the result is always another ArrayLike:

```

>>> x = ArrayLike([1, 2, 3])
>>> x - 1
ArrayLike(array([0, 1, 2]))
>>> 1 - x
ArrayLike(array([ 0, -1, -2]))
>>> np.arange(3) - x
ArrayLike(array([-1, -1, -1]))
>>> x - np.arange(3)
ArrayLike(array([1, 1, 1]))

```

Note that unlike `numpy.ndarray`, `ArrayLike` does not allow operations with arbitrary, unrecognized types.

This ensures that interactions with ArrayLike preserve a well-defined casting hierarchy.

IO related functions.

Classes

<code>DataSource([destpath])</code>	A generic data source file (file, http, ftp, ...).
<code>NpzFile(fid)</code>	A dictionary-like object with lazy-loading of files in the zipped archive provided on construction.

class `numpy.lib.npyio.DataSource` (*destpath*='.')

A generic data source file (file, http, ftp, ...).

DataSources can be local files or remote files/URLs. The files may also be compressed or uncompressed. DataSource hides some of the low-level details of downloading the file, allowing you to simply pass in a valid file path (or URL) and obtain a file object.

Parameters

destpath

[str or None, optional] Path to the directory where the source file gets downloaded to for use. If *destpath* is None, a temporary directory will be created. The default path is the current directory.

Methods

<code>abspath(path)</code>	Return absolute path of file in the DataSource directory.
<code>exists(path)</code>	Test if path exists.
<code>open(path[, mode, encoding, newline])</code>	Open and return file-like object.

method

`lib.npyio.DataSource.abspath` (*path*)

Return absolute path of file in the DataSource directory.

If *path* is a URL, then `abspath` will return either the location the file exists locally or the location it would exist when opened using the `open` method.

Parameters

path

[str or pathlib.Path] Can be a local file or a remote URL.

Returns

out

[str] Complete path, including the *DataSource* destination directory.

Notes

The functionality is based on `os.path.abspath`.

method

`lib.npyio.DataSource.exists(path)`

Test if path exists.

Test if *path* exists as (and in this order):

- a local file.
- a remote URL that has been downloaded and stored locally in the *DataSource* directory.
- a remote URL that has not been downloaded, but is valid and accessible.

Parameters

path

[str or pathlib.Path] Can be a local file or a remote URL.

Returns

out

[bool] True if *path* exists.

Notes

When *path* is a URL, *exists* will return True if it's either stored locally in the *DataSource* directory, or is a valid remote URL. *DataSource* does not discriminate between the two, the file is accessible if it exists in either location.

method

`lib.npyio.DataSource.open(path, mode='r', encoding=None, newline=None)`

Open and return file-like object.

If *path* is a URL, it will be downloaded, stored in the *DataSource* directory and opened from there.

Parameters

path

[str or pathlib.Path] Local file path or URL to open.

mode

[{'r', 'w', 'a'}, optional] Mode to open *path*. Mode 'r' for reading, 'w' for writing, 'a' to append. Available modes depend on the type of object specified by *path*. Default is 'r'.

encoding

[{None, str}, optional] Open text file with given encoding. The default encoding will be what *open* uses.

newline

[{None, str}, optional] Newline to use when reading text file.

Returns

out

[file object] File object.

Notes

URLs require a scheme string (`http://`) to be used, without it they will fail:

```
>>> repos = np.lib.npyio.DataSource()
>>> repos.exists('www.google.com/index.html')
False
>>> repos.exists('http://www.google.com/index.html')
True
```

Temporary directories are deleted when the `DataSource` is deleted.

Examples

```
>>> ds = np.lib.npyio.DataSource('/home/guido')
>>> urlname = 'http://www.google.com/'
>>> gfile = ds.open('http://www.google.com/')
>>> ds.abspath(urlname)
'/home/guido/www.google.com/index.html'

>>> ds = np.lib.npyio.DataSource(None) # use with temporary file
>>> ds.open('/home/guido/foobar.txt')
<open file '/home/guido/foobar.txt', mode 'r' at 0x91d4430>
>>> ds.abspath('/home/guido/foobar.txt')
'/tmp/.../home/guido/foobar.txt'
```

class `numpy.lib.npyio.NpzFile` (*fid*)

A dictionary-like object with lazy-loading of files in the zipped archive provided on construction.

NpzFile is used to load files in the NumPy `.npz` data archive format. It assumes that files in the archive have a `.npz` extension, other files are ignored.

The arrays and file strings are lazily loaded on either `getitem` access using `obj['key']` or attribute lookup using `obj.f.key`. A list of all files (without `.npz` extensions) can be obtained with `obj.files` and the `ZipFile` object itself using `obj.zip`.

Parameters

fid

[file, str, or `pathlib.Path`] The zipped archive to open. This is either a file-like object or a string containing the path to the archive.

own_fid

[bool, optional] Whether `NpzFile` should close the file handle. Requires that `fid` is a file-like object.

Attributes

files

[list of str] List of all files in the archive with a `.npz` extension.

zip

[`ZipFile` instance] The `ZipFile` object initialized with the zipped archive.

f

[`BagObj` instance] An object on which attribute can be performed as an alternative to `getitem` access on the *NpzFile* instance itself.

allow_pickle

[bool, optional] Allow loading pickled data. Default: False

pickle_kwargs

[dict, optional] Additional keyword arguments to pass on to pickle.load. These are only useful when loading object arrays saved on Python 2.

max_header_size

[int, optional] Maximum allowed size of the header. Large headers may not be safe to load securely and thus require explicitly passing a larger value. See `ast.literal_eval` for details. This option is ignored when `allow_pickle` is passed. In that case the file is by definition trusted and the limit is unnecessary.

Methods

<code>close()</code>	Close the file.
<code>get(key[, default])</code>	<code>D.get(k,[,d])</code> returns <code>D[k]</code> if <code>k</code> in <code>D</code> , else <code>d</code> .
<code>items()</code>	<code>D.items()</code> returns a set-like object providing a view on the items
<code>keys()</code>	<code>D.keys()</code> returns a set-like object providing a view on the keys
<code>values()</code>	<code>D.values()</code> returns a set-like object providing a view on the values

method

```
lib.npyio.NpzFile.close()
```

Close the file.

method

```
lib.npyio.NpzFile.get(key, default=None, /)
```

`D.get(k,[,d])` returns `D[k]` if `k` in `D`, else `d`. `d` defaults to `None`.

method

```
lib.npyio.NpzFile.items()
```

`D.items()` returns a set-like object providing a view on the items

method

```
lib.npyio.NpzFile.keys()
```

`D.keys()` returns a set-like object providing a view on the keys

method

```
lib.npyio.NpzFile.values()
```

`D.values()` returns a set-like object providing a view on the values

Examples

```
>>> import numpy as np
>>> from tempfile import TemporaryFile
>>> outfile = TemporaryFile()
>>> x = np.arange(10)
>>> y = np.sin(x)
>>> np.savez(outfile, x=x, y=y)
>>> _ = outfile.seek(0)
```

```
>>> npz = np.load(outfile)
>>> isinstance(npz, np.lib.npyio.NpzFile)
True
>>> npz
NpzFile 'object' with keys: x, y
>>> sorted(npz.files)
['x', 'y']
>>> npz['x'] # getitem access
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> npz.f.x # attribute lookup
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
```

Wrapper functions to more user-friendly calling of certain math functions whose output data-type is different than the input data-type in certain domains of the input.

For example, for functions like `log` with branch cuts, the versions in this module provide the mathematically valid answers in the complex plane:

```
>>> import math
>>> np.emath.log(-math.exp(1)) == (1+1j*math.pi)
True
```

Similarly, `sqrt`, other base logarithms, `power` and trig functions are correctly handled. See their respective docstrings for specific examples.

Functions

<code>arccos(x)</code>	Compute the inverse cosine of x .
<code>arcsin(x)</code>	Compute the inverse sine of x .
<code>arctanh(x)</code>	Compute the inverse hyperbolic tangent of x .
<code>log(x)</code>	Compute the natural logarithm of x .
<code>log10(x)</code>	Compute the logarithm base 10 of x .
<code>log2(x)</code>	Compute the logarithm base 2 of x .
<code>logn(n, x)</code>	Take log base n of x .
<code>power(x, p)</code>	Return x to the power p , $(x**p)$.
<code>sqrt(x)</code>	Compute the square root of x .

`lib.scimath.arccos(x)`

Compute the inverse cosine of x .

Return the “principal value” (for a description of this, see `numpy.arccos`) of the inverse cosine of x . For real x such that $abs(x) \leq 1$, this is a real number in the closed interval $[0, \pi]$. Otherwise, the complex principle value is returned.

Parameters

x
[array_like or scalar] The value(s) whose arccos is (are) required.

Returns

out
[ndarray or scalar] The inverse cosine(s) of the *x* value(s). If *x* was a scalar, so is *out*, otherwise an array object is returned.

See also:

[*numpy.arccos*](#)

Notes

For an arccos() that returns NAN when real *x* is not in the interval $[-1, 1]$, use [*numpy.arccos*](#).

Examples

```
>>> import numpy as np
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.arccos(1) # a scalar is returned
0.0
```

```
>>> np.emath.arccos([1,2])
array([0.-0.j      , 0.-1.317j])
```

`lib.scimath.arcsin(x)`

Compute the inverse sine of *x*.

Return the “principal value” (for a description of this, see [*numpy.arcsin*](#)) of the inverse sine of *x*. For real *x* such that $abs(x) \leq 1$, this is a real number in the closed interval $[-\pi/2, \pi/2]$. Otherwise, the complex principle value is returned.

Parameters

x
[array_like or scalar] The value(s) whose arcsin is (are) required.

Returns

out
[ndarray or scalar] The inverse sine(s) of the *x* value(s). If *x* was a scalar, so is *out*, otherwise an array object is returned.

See also:

[*numpy.arcsin*](#)

Notes

For an `arcsin()` that returns NAN when real x is not in the interval $[-1, 1]$, use `numpy.arcsin`.

Examples

```
>>> import numpy as np
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.arcsin(0)
0.0
```

```
>>> np.emath.arcsin([0, 1])
array([0.      ,  1.5708])
```

`lib.scimath.arctanh(x)`

Compute the inverse hyperbolic tangent of x .

Return the “principal value” (for a description of this, see `numpy.arctanh`) of `arctanh(x)`. For real x such that $\text{abs}(x) < 1$, this is a real number. If $\text{abs}(x) > 1$, or if x is complex, the result is complex. Finally, $x = 1$ returns `inf` and $x = -1$ returns `-inf`.

Parameters

x

[array_like] The value(s) whose `arctanh` is (are) required.

Returns

out

[ndarray or scalar] The inverse hyperbolic tangent(s) of the x value(s). If x was a scalar so is *out*, otherwise an array is returned.

See also:

`numpy.arctanh`

Notes

For an `arctanh()` that returns NAN when real x is not in the interval $(-1, 1)$, use `numpy.arctanh` (this latter, however, does return $\pm\text{inf}$ for $x = \pm 1$).

Examples

```
>>> import numpy as np
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.arctanh(0.5)
0.5493061443340549
```

```
>>> import warnings
>>> with warnings.catch_warnings():
...     warnings.simplefilter('ignore', RuntimeWarning)
...     np.emath.arctanh(np.eye(2))
array([[inf,  0.],
       [ 0., inf]])
>>> np.emath.arctanh([1j])
array([0.+0.7854j])
```

`lib.scimath.log(x)`

Compute the natural logarithm of x .

Return the “principal value” (for a description of this, see [numpy.log](#)) of $\log_e(x)$. For real $x > 0$, this is a real number ($\log(0)$ returns $-\text{inf}$ and $\log(\text{np.inf})$ returns inf). Otherwise, the complex principle value is returned.

Parameters

x

[array_like] The value(s) whose log is (are) required.

Returns

out

[ndarray or scalar] The log of the x value(s). If x was a scalar, so is *out*, otherwise an array is returned.

See also:

[numpy.log](#)

Notes

For a `log()` that returns `NAN` when real $x < 0$, use [numpy.log](#) (note, however, that otherwise [numpy.log](#) and this `log` are identical, i.e., both return $-\text{inf}$ for $x = 0$, inf for $x = \text{inf}$, and, notably, the complex principle value if $x.\text{imag} \neq 0$).

Examples

```
>>> import numpy as np
>>> np.emath.log(np.exp(1))
1.0
```

Negative arguments are handled “correctly” (recall that $\exp(\log(x)) == x$ does *not* hold for real $x < 0$):

```
>>> np.emath.log(-np.exp(1)) == (1 + np.pi * 1j)
True
```

`lib.scimath.log10(x)`

Compute the logarithm base 10 of x .

Return the “principal value” (for a description of this, see [numpy.log10](#)) of $\log_{10}(x)$. For real $x > 0$, this is a real number ($\log_{10}(0)$ returns $-\text{inf}$ and $\log_{10}(\text{np.inf})$ returns inf). Otherwise, the complex principle value is returned.

Parameters

x
[array_like or scalar] The value(s) whose log base 10 is (are) required.

Returns

out
[ndarray or scalar] The log base 10 of the *x* value(s). If *x* was a scalar, so is *out*, otherwise an array object is returned.

See also:

[`numpy.log10`](#)

Notes

For a `log10()` that returns `NAN` when real $x < 0$, use [`numpy.log10`](#) (note, however, that otherwise [`numpy.log10`](#) and this `log10` are identical, i.e., both return `-inf` for $x = 0$, `inf` for $x = \text{inf}$, and, notably, the complex principle value if $x.\text{imag} \neq 0$).

Examples

```
>>> import numpy as np
```

(We set the printing precision so the example can be auto-tested)

```
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.log10(10**1)
1.0
```

```
>>> np.emath.log10([-10**1, -10**2, 10**2])
array([1.+1.3644j, 2.+1.3644j, 2.+0.j      ])
```

`lib.scimath.log2(x)`

Compute the logarithm base 2 of *x*.

Return the “principal value” (for a description of this, see [`numpy.log2`](#)) of $\log_2(x)$. For real $x > 0$, this is a real number (`log2(0)` returns `-inf` and `log2(np.inf)` returns `inf`). Otherwise, the complex principle value is returned.

Parameters

x
[array_like] The value(s) whose log base 2 is (are) required.

Returns

out
[ndarray or scalar] The log base 2 of the *x* value(s). If *x* was a scalar, so is *out*, otherwise an array is returned.

See also:

[`numpy.log2`](#)

Notes

For a `log2()` that returns `NAN` when real $x < 0$, use `numpy.log2` (note, however, that otherwise `numpy.log2` and this `log2` are identical, i.e., both return `-inf` for $x = 0$, `inf` for $x = inf$, and, notably, the complex principle value if $x.\text{imag} \neq 0$).

Examples

We set the printing precision so the example can be auto-tested:

```
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.log2(8)
3.0
>>> np.emath.log2([-4, -8, 8])
array([2.+4.5324j, 3.+4.5324j, 3.+0.j      ])
```

`lib.scimath.logn(n, x)`

Take log base *n* of *x*.

If *x* contains negative inputs, the answer is computed and returned in the complex domain.

Parameters

- n**
[array_like] The integer base(s) in which the log is taken.
- x**
[array_like] The value(s) whose log base *n* is (are) required.

Returns

- out**
[ndarray or scalar] The log base *n* of the *x* value(s). If *x* was a scalar, so is *out*, otherwise an array is returned.

Examples

```
>>> import numpy as np
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.logn(2, [4, 8])
array([2., 3.])
>>> np.emath.logn(2, [-4, -8, 8])
array([2.+4.5324j, 3.+4.5324j, 3.+0.j      ])
```

`lib.scimath.power(x, p)`

Return *x* to the power *p*, (x^{**p}).

If *x* contains negative values, the output is converted to the complex domain.

Parameters

- x**
[array_like] The input value(s).

p

[array_like of ints] The power(s) to which x is raised. If x contains multiple values, p has to either be a scalar, or contain the same number of values as x . In the latter case, the result is $x[0]**p[0]$, $x[1]**p[1]$,

Returns**out**

[ndarray or scalar] The result of $x**p$. If x and p are scalars, so is *out*, otherwise an array is returned.

See also:*numpy.power***Examples**

```
>>> import numpy as np
>>> np.set_printoptions(precision=4)
```

```
>>> np.emath.power(2, 2)
4
```

```
>>> np.emath.power([2, 4], 2)
array([ 4, 16])
```

```
>>> np.emath.power([2, 4], -2)
array([0.25 , 0.0625])
```

```
>>> np.emath.power([-2, 4], 2)
array([ 4.-0.j, 16.+0.j])
```

```
>>> np.emath.power([2, 4], [2, 4])
array([ 4, 256])
```

`lib.scimath.sqrt(x)`

Compute the square root of x .

For negative input elements, a complex value is returned (unlike *numpy.sqrt* which returns NaN).

Parameters**x**

[array_like] The input value(s).

Returns**out**

[ndarray or scalar] The square root of x . If x was a scalar, so is *out*, otherwise an array is returned.

See also:*numpy.sqrt*

Examples

For real, non-negative inputs this works just like `numpy.sqrt`:

```
>>> import numpy as np
```

```
>>> np.emath.sqrt(1)
1.0
>>> np.emath.sqrt([1, 4])
array([1.,  2.])
```

But it automatically handles negative inputs:

```
>>> np.emath.sqrt(-1)
1j
>>> np.emath.sqrt([-1, 4])
array([0.+1.j,  2.+0.j])
```

Different results are expected because: floating point 0.0 and -0.0 are distinct.

For more control, explicitly use `complex()` as follows:

```
>>> np.emath.sqrt(complex(-4.0, 0.0))
2j
>>> np.emath.sqrt(complex(-4.0, -0.0))
-2j
```

Utilities that manipulate strides to achieve desirable effects.

An explanation of strides can be found in the [The N-dimensional array \(ndarray\)](#).

Functions

<code>as_strided(x[, shape, strides, subok, ...])</code>	Create a view into the array with the given shape and strides.
<code>sliding_window_view(x, window_shape[, axis, ...])</code>	Create a sliding window view into the array with the given window shape.

```
lib.stride_tricks.as_strided(x, shape=None, strides=None, subok=False, writeable=True, *,
                               check_bounds=None)
```

Create a view into the array with the given shape and strides.

Warning: This function has to be used with extreme care, see notes.

Parameters

x

[ndarray] Array to create a new.

shape

[sequence of int, optional] The shape of the new array. Defaults to `x.shape`.

strides

[sequence of int, optional] The strides of the new array. Defaults to `x.strides`.

subok

[bool, optional] If True, subclasses are preserved.

writeable

[bool, optional] If set to False, the returned array will always be readonly. Otherwise it will be writable if the original array was. It is advisable to set this to False if possible (see Notes).

check_bounds

[bool or None] Check new stride and shape for potential out of bound memory access.

Returns**view**

[ndarray]

Raises**ValueError**

If *check_bounds* is True the given shape and strides could result in out-of-bounds memory access.

See also:***broadcast_to***

broadcast an array to a given shape.

reshape

reshape an array.

lib.stride_tricks.sliding_window_view

userfriendly and safe function for a creation of sliding window views.

Notes

as_strided creates a view into the array given the exact strides and shape. This means it manipulates the internal data structure of ndarray and, if done incorrectly, the array elements can point to invalid memory and can corrupt results or crash your program. It is advisable to always use the original *x.strides* when calculating new strides to avoid reliance on a contiguous memory layout.

Furthermore, arrays created with this function often contain self overlapping memory, so that two elements are identical. Vectorized write operations on such arrays will typically be unpredictable. They may even give different results for small, large, or transposed arrays.

Since writing to these arrays has to be tested and done with great care, you may want to use *writeable=False* to avoid accidental write operations.

For these reasons it is advisable to avoid *as_strided* when possible.

Examples

```
>>> import numpy as np
... from numpy.lib.stride_tricks import as_strided
... x = np.arange(10)
... y = as_strided(x, shape=(5,), strides=(8,), check_bounds=True)
... y
array([0, 1, 2, 3, 4])
```

Attempting to create an out-of-bounds view and use `check_bounds=True` as `as_strided` will raises an error:

```
>>> as_strided(x, shape=(20,), strides=(8,), check_bounds=True)
Traceback (most recent call last):
...
ValueError: Given shape and strides would access memory out of bounds...
```

When working with views, bounds are checked against the base array:

```
>>> a = np.arange(1000)
... b = a[:2]
... c = as_strided(b, shape=(2,), strides=(400,), check_bounds=True)
... c[0], c[1]
(0, 50)
```

`lib.stride_tricks.sliding_window_view(x, window_shape, axis=None, *, subok=False, writeable=False)`

Create a sliding window view into the array with the given window shape.

Also known as rolling or moving window, the window slides across all dimensions of the array and extracts subsets of the array at all window positions.

New in version 1.20.0.

Parameters

x

[array_like] Array to create the sliding window view from.

window_shape

[int or tuple of int] Size of window over each axis that takes part in the sliding window. If *axis* is not present, must have same length as the number of input array dimensions. Single integers *i* are treated as if they were the tuple (*i*,).

axis

[int or tuple of int, optional] Axis or axes along which the sliding window is applied. By default, the sliding window is applied to all axes and `window_shape[i]` will refer to axis *i* of *x*. If *axis* is given as a *tuple of int*, `window_shape[i]` will refer to the axis `axis[i]` of *x*. Single integers *i* are treated as if they were the tuple (*i*,).

subok

[bool, optional] If True, sub-classes will be passed-through, otherwise the returned array will be forced to be a base-class array (default).

writeable

[bool, optional] When true, allow writing to the returned view. The default is false, as this should be used with caution: the returned view contains the same memory location multiple times, so writing to one location will cause others to change.

Returns

view

[ndarray] Sliding window view of the array. The sliding window dimensions are inserted at the end, and the original dimensions are trimmed as required by the size of the sliding window. That is, `view.shape = x_shape_trimmed + window_shape`, where `x_shape_trimmed` is `x.shape` with every entry reduced by one less than the corresponding window size.

See also:**`lib.stride_tricks.as_strided`**

A lower-level and less safe routine for creating arbitrary views from custom shape and strides. Use the `check_bounds` parameter for bounds validation.

`broadcast_to`

broadcast an array to a given shape.

Notes

Warning: This function creates views with overlapping memory. When `writable=True`, writing to the view will modify the original array and may affect multiple view positions. See the examples below and this guide about the difference between copies and views.

For many applications using a sliding window view can be convenient, but potentially very slow. Often specialized solutions exist, for example:

- `scipy.signal.fftconvolve`
- filtering functions in `scipy.ndimage`
- moving window functions provided by `bottleneck`.

As a rough estimate, a sliding window approach with an input size of N and a window size of W will scale as $O(N*W)$ where frequently a special algorithm can achieve $O(N)$. That means that the sliding window variant for a window size of 100 can be a 100 times slower than a more specialized version.

Nevertheless, for small window sizes, when no custom algorithm exists, or as a prototyping and developing tool, this function can be a good solution.

Examples

```
>>> import numpy as np
>>> from numpy.lib.stride_tricks import sliding_window_view
>>> x = np.arange(6)
>>> x.shape
(6,)
>>> v = sliding_window_view(x, 3)
>>> v.shape
(4, 3)
>>> v
array([[0, 1, 2],
       [1, 2, 3],
       [2, 3, 4],
       [3, 4, 5]])
```

This also works in more dimensions, e.g.

```

>>> i, j = np.ogrid[:3, :4]
>>> x = 10*i + j
>>> x.shape
(3, 4)
>>> x
array([[ 0,  1,  2,  3],
       [10, 11, 12, 13],
       [20, 21, 22, 23]])
>>> shape = (2,2)
>>> v = sliding_window_view(x, shape)
>>> v.shape
(2, 3, 2, 2)
>>> v
array([[[[ 0,  1],
          [10, 11]],
        [[ 1,  2],
          [11, 12]],
        [[ 2,  3],
          [12, 13]]],
       [[10, 11],
        [20, 21]],
       [[11, 12],
        [21, 22]],
       [[12, 13],
        [22, 23]]]])

```

The axis can be specified explicitly:

```

>>> v = sliding_window_view(x, 3, 0)
>>> v.shape
(1, 4, 3)
>>> v
array([[[ 0, 10, 20],
        [ 1, 11, 21],
        [ 2, 12, 22],
        [ 3, 13, 23]]]])

```

The same axis can be used several times. In that case, every use reduces the corresponding original dimension:

```

>>> v = sliding_window_view(x, (2, 3), (1, 1))
>>> v.shape
(3, 1, 2, 3)
>>> v
array([[[[ 0,  1,  2],
          [ 1,  2,  3]]],
       [[10, 11, 12],
        [11, 12, 13]]],
       [[20, 21, 22],
        [21, 22, 23]]]])

```

Combining with stepped slicing (*::step*), this can be used to take sliding views which skip elements:

```

>>> x = np.arange(7)
>>> sliding_window_view(x, 5)[: , ::2]
array([[0, 2, 4],
       [1, 3, 5],
       [2, 4, 6]])

```

or views which move by multiple elements

```
>>> x = np.arange(7)
>>> sliding_window_view(x, 3)[::2, :]
array([[0, 1, 2],
       [2, 3, 4],
       [4, 5, 6]])
```

A common application of `sliding_window_view` is the calculation of running statistics. The simplest example is the [moving average](#):

```
>>> x = np.arange(6)
>>> x.shape
(6,)
>>> v = sliding_window_view(x, 3)
>>> v.shape
(4, 3)
>>> v
array([[0, 1, 2],
       [1, 2, 3],
       [2, 3, 4],
       [3, 4, 5]])
>>> moving_average = v.mean(axis=-1)
>>> moving_average
array([1., 2., 3., 4.])
```

To adjust the step size of the sliding window, index the output view along the desired dimension(s). Using the array shown above:

```
>>> v[:,::2]
array([[0, 1, 2],
       [2, 3, 4]])
```

You can slide in the reverse direction using the same technique:

```
>>> v[:,::-1]
array([[3, 4, 5],
       [2, 3, 4],
       [1, 2, 3],
       [0, 1, 2]])
```

The two examples below demonstrate the effect of `writable=True`.

Creating a view with the default `writable=False` and then writing to it raises an error.

```
>>> v = sliding_window_view(x, 3)
>>> v[0,1] = 10
Traceback (most recent call last):
...
ValueError: assignment destination is read-only
```

Creating a view with `writable=True` and then writing to it changes the original array and multiple view positions.

```
>>> x = np.arange(6) # reset x for the second example
>>> v = sliding_window_view(x, 3, writable=True)
>>> v[0,1] = 10
>>> x
```

(continues on next page)

(continued from previous page)

```
array([ 0, 10,  2,  3,  4,  5])
>>> v
array([[ 0, 10,  2],
       [10,  2,  3],
       [ 2,  3,  4],
       [ 3,  4,  5]])
```

Note that a sliding window approach is often **not** optimal (see Notes).

Record Arrays (`numpy.rec`)

Record arrays expose the fields of structured arrays as properties.

Most commonly, ndarrays contain elements of a single type, e.g. floats, integers, bools etc. However, it is possible for elements to be combinations of these using structured types, such as:

```
>>> import numpy as np
>>> a = np.array([(1, 2.0), (1, 2.0)],
...              dtype=[('x', np.int64), ('y', np.float64)])
>>> a
array([(1, 2.), (1, 2.)], dtype=[('x', '<i8'), ('y', '<f8')])
```

Here, each element consists of two fields: x (and int), and y (a float). This is known as a structured array. The different fields are analogous to columns in a spread-sheet. The different fields can be accessed as one would a dictionary:

```
>>> a['x']
array([1, 1])
```

```
>>> a['y']
array([2., 2.])
```

Record arrays allow us to access fields as properties:

```
>>> ar = np.rec.array(a)
>>> ar.x
array([1, 1])
>>> ar.y
array([2., 2.])
```

Functions

<code>array(obj[, dtype, shape, offset, strides, ...])</code>	Construct a record array from a wide-variety of objects.
<code>find_duplicate(list)</code>	Find duplication in a list, return a list of duplicated elements
<code>format_parser(formats, names, titles[, ...])</code>	Class to convert formats, names, titles description to a dtype.
<code>fromarrays(arrayList[, dtype, shape, ...])</code>	Create a record array from a (flat) list of arrays
<code>fromfile(fd[, dtype, shape, offset, ...])</code>	Create an array from binary file data
<code>fromrecords(recList[, dtype, shape, ...])</code>	Create a recarray from a list of records in text form.
<code>fromstring(datastring[, dtype, shape, ...])</code>	Create a record array from binary data

`rec.array` (*obj*, *dtype=None*, *shape=None*, *offset=0*, *strides=None*, *formats=None*, *names=None*, *titles=None*, *aligned=False*, *byteorder=None*, *copy=True*)

Construct a record array from a wide-variety of objects.

A general-purpose record array constructor that dispatches to the appropriate *recarray* creation function based on the inputs (see Notes).

Parameters

obj

[any] Input object. See Notes for details on how various input types are treated.

dtype

[data-type, optional] Valid dtype for array.

shape

[int or tuple of ints, optional] Shape of each array.

offset

[int, optional] Position in the file or buffer to start reading from.

strides

[tuple of ints, optional] Buffer (*buf*) is interpreted according to these strides (strides define how many bytes each array element, row, column, etc. occupy in memory).

formats, names, titles, aligned, byteorder

If *dtype* is None, these arguments are passed to *numpy.format_parser* to construct a dtype. See that function for detailed documentation.

copy

[bool, optional] Whether to copy the input object (True), or to use a reference instead. This option only applies when the input is an ndarray or recarray. Defaults to True.

Returns

np.recarray

Record array created from the specified object.

Notes

If *obj* is None, then call the *recarray* constructor. If *obj* is a string, then call the *fromstring* constructor. If *obj* is a list or a tuple, then if the first object is an *ndarray*, call *fromarrays*, otherwise call *fromrecords*. If *obj* is a *recarray*, then make a copy of the data in the recarray (if *copy*=True) and use the new formats, names, and titles. If *obj* is a file, then call *fromfile*. Finally, if *obj* is an *ndarray*, then return *obj.view(recarray)*, making a copy of the data if *copy*=True.

Examples

```
>>> a = np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
>>> a
array([[1, 2, 3],
       [4, 5, 6],
       [7, 8, 9]])
```

```
>>> np.rec.array(a)
rec.array([[1, 2, 3],
          [4, 5, 6],
          [7, 8, 9]],
          dtype=int64)
```

```
>>> b = [(1, 1), (2, 4), (3, 9)]
>>> c = np.rec.array(b, formats = ['i2', 'f2'], names = ('x', 'y'))
>>> c
rec.array([(1, 1.), (2, 4.), (3, 9.)],
          dtype=[('x', '<i2'), ('y', '<f2')])
```

```
>>> c.x
array([1, 2, 3], dtype=int16)
```

```
>>> c.y
array([1., 4., 9.], dtype=float16)
```

```
>>> r = np.rec.array(['abc', 'def'], names=['col1', 'col2'])
>>> print(r.col1)
abc
```

```
>>> r.col1
array('abc', dtype='<U3')
```

```
>>> r.col2
array('def', dtype='<U3')
```

`rec.find_duplicate` (*list*)

Find duplication in a list, return a list of duplicated elements

class `numpy.rec.format_parser` (*formats, names, titles, aligned=False, byteorder=None*)

Class to convert formats, names, titles description to a dtype.

After constructing the `format_parser` object, the `dtype` attribute is the converted data-type: `dtype = format_parser(formats, names, titles).dtype`

Parameters

formats

[str or list of str] The format description, either specified as a string with comma-separated format descriptions in the form '`f8, i4, S5`', or a list of format description strings in the form `['f8', 'i4', 'S5']`.

names

[str or list/tuple of str] The field names, either specified as a comma-separated string in the form '`col1, col2, col3`', or as a list or tuple of strings in the form `['col1', 'col2', 'col3']`. An empty list can be used, in that case default field names (`'f0', 'f1', ...`) are used.

titles

[sequence] Sequence of title strings. An empty list can be used to leave titles out.

aligned

[bool, optional] If True, align the fields by padding as the C-compiler would. Default is False.

byteorder

[str, optional] If specified, all the fields will be changed to the provided byte-order. Otherwise, the default byte-order is used. For all available string specifiers, see `dtype.newbyteorder`.

Attributes

dtype

[dtype] The converted data-type.

See also:

`numpy.dtype`, `numpy.typecode`

Examples

```
>>> import numpy as np
>>> np.rec.format_parser(['<f8', '<i4'], ['col1', 'col2'],
...                      ['T1', 'T2']).dtype
dtype([(('T1', 'col1'), '<f8'), (('T2', 'col2'), '<i4')])
```

names and/or *titles* can be empty lists. If *titles* is an empty list, titles will simply not appear. If *names* is empty, default field names will be used.

```
>>> np.rec.format_parser(['f8', 'i4', 'S5'], ['col1', 'col2', 'col3'],
...                      []).dtype
dtype([('col1', '<f8'), ('col2', '<i4'), ('col3', '<S5')])
>>> np.rec.format_parser(['<f8', '<i4', '<S5'], [], []).dtype
dtype([('f0', '<f8'), ('f1', '<i4'), ('f2', 'S5')])
```

`rec.fromarrays` (*arrayList*, *dtype=None*, *shape=None*, *formats=None*, *names=None*, *titles=None*, *aligned=False*, *byteorder=None*)

Create a record array from a (flat) list of arrays

Parameters

arrayList

[list or tuple] List of array-like objects (such as lists, tuples, and ndarrays).

dtype

[data-type, optional] valid dtype for all arrays

shape

[int or tuple of ints, optional] Shape of the resulting array. If not provided, inferred from `arrayList[0]`.

formats, names, titles, aligned, byteorder

If *dtype* is `None`, these arguments are passed to `numpy.rec.format_parser` to construct a dtype. See that function for detailed documentation.

Returns

np.recarray

Record array consisting of given `arrayList` columns.

Examples

```
>>> x1=np.array([1,2,3,4])
>>> x2=np.array(['a','dd','xyz','12'])
>>> x3=np.array([1.1,2,3,4])
>>> r = np.rec.fromarrays([x1,x2,x3],names='a,b,c')
>>> print(r[1])
(2, 'dd', 2.0) # may vary
>>> x1[1]=34
>>> r.a
array([1, 2, 3, 4])
```

```

>>> x1 = np.array([1, 2, 3, 4])
>>> x2 = np.array(['a', 'dd', 'xyz', '12'])
>>> x3 = np.array([1.1, 2, 3, 4])
>>> r = np.rec.fromarrays(
...     [x1, x2, x3],
...     dtype=np.dtype([('a', np.int32), ('b', 'S3'), ('c', np.float32)]))
>>> r
rec.array([(1, b'a', 1.1), (2, b'dd', 2. ), (3, b'xyz', 3. ),
          (4, b'12', 4. )],
          dtype=[('a', '<i4'), ('b', 'S3'), ('c', '<f4')])

```

`rec.fromfile` (*fd*, *dtype=None*, *shape=None*, *offset=0*, *formats=None*, *names=None*, *titles=None*, *aligned=False*, *byteorder=None*)

Create an array from binary file data

Parameters

fd

[str or file type] If file is a string or a path-like object then that file is opened, else it is assumed to be a file object. The file object must support random access (i.e. it must have tell and seek methods).

dtype

[data-type, optional] valid dtype for all arrays

shape

[int or tuple of ints, optional] shape of each array.

offset

[int, optional] Position in the file to start reading from.

formats, names, titles, aligned, byteorder

If *dtype* is None, these arguments are passed to *numpy.format_parser* to construct a dtype. See that function for detailed documentation

Returns

np.recarray

record array consisting of data enclosed in file.

Examples

```

>>> from tempfile import TemporaryFile
>>> a = np.empty(10, dtype='f8,i4,S5')
>>> a[5] = (0.5, 10, 'abcde')
>>>
>>> fd=TemporaryFile()
>>> a = a.view(a.dtype.newbyteorder('<'))
>>> a.tofile(fd)
>>>
>>> _ = fd.seek(0)
>>> r=np.rec.fromfile(fd, formats='f8,i4,S5', shape=10,
... byteorder='<')
>>> print(r[5])
(0.5, 10, b'abcde')
>>> r.shape
(10,)

```

`rec.fromrecords` (*recList*, *dtype=None*, *shape=None*, *formats=None*, *names=None*, *titles=None*, *aligned=False*, *byteorder=None*)

Create a recarray from a list of records in text form.

Parameters

recList

[sequence] data in the same field may be heterogeneous - they will be promoted to the highest data type.

dtype

[data-type, optional] valid dtype for all arrays

shape

[int or tuple of ints, optional] shape of each array.

formats, names, titles, aligned, byteorder

If *dtype* is None, these arguments are passed to `numpy.format_parser` to construct a dtype. See that function for detailed documentation.

If both *formats* and *dtype* are None, then this will auto-detect formats. Use list of tuples rather than list of lists for faster processing.

Returns

np.recarray

record array consisting of given recList rows.

Examples

```
>>> r=np.rec.fromrecords([(456,'dbe',1.2),(2,'de',1.3)],
... names='col1,col2,col3')
>>> print(r[0])
(456, 'dbe', 1.2)
>>> r.col1
array([456,  2])
>>> r.col2
array(['dbe', 'de'], dtype='<U3')
>>> import pickle
>>> pickle.loads(pickle.dumps(r))
rec.array([(456, 'dbe', 1.2), ( 2, 'de', 1.3)],
          dtype=[('col1', '<i8'), ('col2', '<U3'), ('col3', '<f8')])
```

`rec.fromstring` (*datastring*, *dtype=None*, *shape=None*, *offset=0*, *formats=None*, *names=None*, *titles=None*, *aligned=False*, *byteorder=None*)

Create a record array from binary data

Note that despite the name of this function it does not accept *str* instances.

Parameters

datastring

[bytes-like] Buffer of binary data

dtype

[data-type, optional] Valid dtype for all arrays

shape

[int or tuple of ints, optional] Shape of each array.

offset

[int, optional] Position in the buffer to start reading from.

formats, names, titles, aligned, byteorder

If *dtype* is None, these arguments are passed to *numpy.format_parser* to construct a dtype. See that function for detailed documentation.

Returns**np.recarray**

Record array view into the data in *datastring*. This will be readonly if *datastring* is readonly.

See also:

numpy.frombuffer

Examples

```
>>> a = b'\x01\x02\x03abc'
>>> np.rec.fromstring(a, dtype='u1,u1,u1,S3')
rec.array([(1, 2, 3, b'abc')],
          dtype=[('f0', 'u1'), ('f1', 'u1'), ('f2', 'u1'), ('f3', 'S3')])
```

```
>>> grades_dtype = [('Name', (np.str_, 10)), ('Marks', np.float64),
...                 ('GradeLevel', np.int32)]
>>> grades_array = np.array([('Sam', 33.3, 3), ('Mike', 44.4, 5),
...                         ('Aadi', 66.6, 6)], dtype=grades_dtype)
>>> np.rec.fromstring(grades_array.tobytes(), dtype=grades_dtype)
rec.array([('Sam', 33.3, 3), ('Mike', 44.4, 5), ('Aadi', 66.6, 6)],
          dtype=[('Name', '<U10'), ('Marks', '<f8'), ('GradeLevel', '<i4')])
```

```
>>> s = '\x01\x02\x03abc'
>>> np.rec.fromstring(s, dtype='u1,u1,u1,S3')
Traceback (most recent call last):
...
TypeError: a bytes-like object is required, not 'str'
```

Also, the *numpy.recarray* class and the *numpy.record* scalar dtype are present in this namespace.

Version information

The *numpy.version* submodule includes several constants that expose more detailed information about the exact version of the installed *numpy* package:

numpy.version.version

Version string for the installed package - matches *numpy.__version__*.

numpy.version.full_version

Version string - the same as *numpy.version.version*.

numpy.version.short_version

Version string without any local build identifiers.

Examples

```
>>> np.__version__
'2.1.0.dev0+git20240319.2ea7ce0' # may vary
>>> np.version.short_version
'2.1.0.dev0' # may vary
```

`numpy.version.git_revision`

String containing the git hash of the commit from which numpy was built.

`numpy.version.release`

True if this version is a numpy release, False if a dev version.

Legacy fixed-width string functionality

Legacy

This submodule is considered legacy and will no longer receive updates. This could also mean it will be removed in future NumPy versions. The string operations in this module are planned to be deprecated in the future, and the `numpy.char.chararray` class is deprecated in NumPy 2.5. Use `numpy.strings` instead.

The `numpy.char` module provides a set of vectorized string operations for arrays of type `numpy.str_` or `numpy.bytes_`. For example

```
>>> import numpy as np
>>> np.char.capitalize(["python", "numpy"])
array(['Python', 'Numpy'], dtype='<U6')
>>> np.char.add(["num", "doc"], ["py", "umentation"])
array(['numpy', 'documentation'], dtype='<U13')
```

The methods in this module are based on the methods in `string`

String operations

<code>add(x1, x2, /[, out, where, casting, order, ...])</code>	Add arguments element-wise.
<code>multiply(a, i)</code>	Return $(a * i)$, that is string multiple concatenation, element-wise.
<code>mod(a, values)</code>	Return $(a \% i)$, that is pre-Python 2.6 string formatting (interpolation), element-wise for a pair of array_likes of str or unicode.
<code>capitalize(a)</code>	Return a copy of <i>a</i> with only the first character of each element capitalized.
<code>center(a, width[, fillchar])</code>	Return a copy of <i>a</i> with its elements centered in a string of length <i>width</i> .
<code>decode(a[, encoding, errors])</code>	Calls <code>bytes.decode</code> element-wise.
<code>encode(a[, encoding, errors])</code>	Calls <code>str.encode</code> element-wise.
<code>expandtabs(a[, tabsize])</code>	Return a copy of each string element where all tab characters are replaced by one or more spaces.
<code>join(sep, seq)</code>	Return a string which is the concatenation of the strings in the sequence <i>seq</i> .
<code>ljust(a, width[, fillchar])</code>	Return an array with the elements of <i>a</i> left-justified in a string of length <i>width</i> .
<code>lower(a)</code>	Return an array with the elements converted to lowercase.
<code>lstrip(a[, chars])</code>	For each element in <i>a</i> , return a copy with the leading characters removed.
<code>partition(a, sep)</code>	Partition each element in <i>a</i> around <i>sep</i> .
<code>replace(a, old, new[, count])</code>	For each element in <i>a</i> , return a copy of the string with occurrences of substring <i>old</i> replaced by <i>new</i> .
<code>rjust(a, width[, fillchar])</code>	Return an array with the elements of <i>a</i> right-justified in a string of length <i>width</i> .
<code>rpartition(a, sep)</code>	Partition (split) each element around the right-most separator.
<code>rsplit(a[, sep, maxsplit])</code>	For each element in <i>a</i> , return a list of the words in the string, using <i>sep</i> as the delimiter string.
<code>rstrip(a[, chars])</code>	For each element in <i>a</i> , return a copy with the trailing characters removed.
<code>split(a[, sep, maxsplit])</code>	For each element in <i>a</i> , return a list of the words in the string, using <i>sep</i> as the delimiter string.
<code>splitlines(a[, keepends])</code>	For each element in <i>a</i> , return a list of the lines in the element, breaking at line boundaries.
<code>strip(a[, chars])</code>	For each element in <i>a</i> , return a copy with the leading and trailing characters removed.
<code>swapcase(a)</code>	Return element-wise a copy of the string with uppercase characters converted to lowercase and vice versa.
<code>title(a)</code>	Return element-wise title cased version of string or unicode.
<code>translate(a, table[, deletechars])</code>	For each element in <i>a</i> , return a copy of the string where all characters occurring in the optional argument <i>deletechars</i> are removed, and the remaining characters have been mapped through the given translation table.
<code>upper(a)</code>	Return an array with the elements converted to uppercase.
<code>zfill(a, width)</code>	Return the numeric string left-filled with zeros.

`char.add(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'add'>`

Add arguments element-wise.

Parameters

x1, x2

[array_like] The arrays to be added. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

add

[ndarray or scalar] The sum of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

Notes

Equivalent to $x1 + x2$ in terms of array broadcasting.

Examples

```
>>> import numpy as np
>>> np.add(1.0, 4.0)
5.0
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> np.add(x1, x2)
array([[ 0.,  2.,  4.],
       [ 3.,  5.,  7.],
       [ 6.,  8., 10.]])
```

The `+` operator can be used as a shorthand for `np.add` on ndarrays.

```
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> x1 + x2
array([[ 0.,  2.,  4.],
       [ 3.,  5.,  7.],
       [ 6.,  8., 10.]])
```

`char.multiply(a, i)`

Return $(a * i)$, that is string multiple concatenation, element-wise.

Values in *i* of less than 0 are treated as 0 (which yields an empty string).

Parameters

- a**
[array_like, with bytes_ or str_ dtype]
- i**
[array_like, with any integer dtype]

Returns

- out**
[ndarray] Output array of str or unicode, depending on input types

Notes

This is a thin wrapper around `np.strings.multiply` that raises *ValueError* when `i` is not an integer. It only exists for backwards-compatibility.

Examples

```
>>> import numpy as np
>>> a = np.array(["a", "b", "c"])
>>> np.strings.multiply(a, 3)
array(['aaa', 'bbb', 'ccc'], dtype='<U3')
>>> i = np.array([1, 2, 3])
>>> np.strings.multiply(a, i)
array(['a', 'bb', 'ccc'], dtype='<U3')
>>> np.strings.multiply(np.array(['a']), i)
array(['a', 'aa', 'aaa'], dtype='<U3')
>>> a = np.array(['a', 'b', 'c', 'd', 'e', 'f']).reshape((2, 3))
>>> np.strings.multiply(a, 3)
array([[ 'aaa', 'bbb', 'ccc'],
       ['ddd', 'eee', 'fff']], dtype='<U3')
>>> np.strings.multiply(a, i)
array([[ 'a', 'bb', 'ccc'],
       ['d', 'ee', 'fff']], dtype='<U3')
```

`char.mod(a, values)`

Return `(a % i)`, that is pre-Python 2.6 string formatting (interpolation), element-wise for a pair of array_likes of str or unicode.

Parameters

- a**
[array_like, with bytes_ or str_ dtype]
- values**
[array_like of values] These values will be element-wise interpolated into the string.

Returns

- out**
[ndarray] Output array of `StringDType`, `bytes_` or `str_` dtype, depending on input types

Examples

```
>>> import numpy as np
>>> a = np.array(["NumPy is a %s library"])
>>> np.strings.mod(a, values=["Python"])
array(['NumPy is a Python library'], dtype='<U25')
```

```
>>> a = np.array([b'%d bytes', b'%d bits'])
>>> values = np.array([8, 64])
>>> np.strings.mod(a, values)
array([b'8 bytes', b'64 bits'], dtype='|S7')
```

`char.capitalize(a)`

Return a copy of *a* with only the first character of each element capitalized.

Calls `str.capitalize` element-wise.

For byte strings, this method is locale-dependent.

Parameters

a
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array of strings to capitalize.

Returns

out
[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.capitalize`

Examples

```
>>> import numpy as np
>>> c = np.array(['a1b2', '1b2a', 'b2a1', '2a1b'], 'S4'); c
array(['a1b2', '1b2a', 'b2a1', '2a1b'],
      dtype='|S4')
>>> np.strings.capitalize(c)
array(['A1b2', '1b2a', 'B2a1', '2a1b'],
      dtype='|S4')
```

`char.center(a, width, fillchar='')`

Return a copy of *a* with its elements centered in a string of length *width*.

Parameters

a
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

width
[array-like, with any integer dtype] The length of the resulting strings, unless `width < str_len(a)`.

fillchar

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Optional padding character to use (default is space).

Returns**out**

[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

[`str.center`](#)

Notes

While it is possible for `a` and `fillchar` to have different dtypes, passing a non-ASCII character in `fillchar` when `a` is of dtype “S” is not allowed, and a `ValueError` is raised.

Examples

```
>>> import numpy as np
>>> c = np.array(['a1b2', '1b2a', 'b2a1', '2a1b']); c
array(['a1b2', '1b2a', 'b2a1', '2a1b'], dtype='<U4')
>>> np.strings.center(c, width=9)
array(['   a1b2  ', '   1b2a  ', '   b2a1  ', '   2a1b  '], dtype='<U9')
>>> np.strings.center(c, width=9, fillchar='*')
array(['***a1b2**', '***1b2a**', '***b2a1**', '***2a1b**'], dtype='<U9')
>>> np.strings.center(c, width=1)
array(['a1b2', '1b2a', 'b2a1', '2a1b'], dtype='<U4')
```

`char.decode(a, encoding=None, errors=None)`

Calls [`bytes.decode`](#) element-wise.

The set of available codecs comes from the Python standard library, and may be extended at runtime. For more information, see the [`codecs`](#) module.

Parameters**a**

[array_like, with `bytes_ dtype`]

encoding

[str, optional] The name of an encoding

errors

[str, optional] Specifies how to handle encoding errors

Returns**out**

[ndarray]

See also:

[`bytes.decode`](#)

Notes

The type of the result will depend on the encoding specified.

Examples

```
>>> import numpy as np
>>> c = np.array([b'\x81\xc1\x81\xc1\x81\xc1', b'@\x81\xc1@@',
...               b'\x81\x82\xc2\xc1\xc2\x82\x81'])
>>> c
array([b'\x81\xc1\x81\xc1\x81\xc1', b'@\x81\xc1@@',
       b'\x81\x82\xc2\xc1\xc2\x82\x81'], dtype='|S7')
>>> np.strings.decode(c, encoding='cp037')
array(['aAaAaA', ' aA ', 'abBABba'], dtype='<U7')
```

`char.encode(a, encoding=None, errors=None)`

Calls `str.encode` element-wise.

The set of available codecs comes from the Python standard library, and may be extended at runtime. For more information, see the `codecs` module.

Parameters

- a**
[array_like, with `StringDType` or `str_ dtype`]
- encoding**
[str, optional] The name of an encoding
- errors**
[str, optional] Specifies how to handle encoding errors

Returns

- out**
[ndarray]

See also:

`str.encode`

Notes

The type of the result will depend on the encoding specified.

Examples

```
>>> import numpy as np
>>> a = np.array(['aAaAaA', ' aA ', 'abBABba'])
>>> np.strings.encode(a, encoding='cp037')
array([b'\x81\x81\x81\x81\x81\x81', b'@\x81\xc1@@',
       b'\x81\x82\xc2\xc1\xc2\x82\x81'], dtype='|S7')
```

`char.expandtabs(a, tabsize=8)`

Return a copy of each string element where all tab characters are replaced by one or more spaces.

Calls `str.expandtabs` element-wise.

Return a copy of each string element where all tab characters are replaced by one or more spaces, depending on the current column and the given *tabsize*. The column number is reset to zero after each newline occurring in the string. This doesn't understand other non-printing characters or escape sequences.

Parameters

a

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array

tabsize

[int, optional] Replace tabs with *tabsize* number of spaces. If not given defaults to 8 spaces.

Returns

out

[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input type

See also:

`str.expandtabs`

Examples

```
>>> import numpy as np
>>> a = np.array(['      Hello   world'])
>>> np.strings.expandtabs(a, tabsize=4)
array(['      Hello   world'], dtype='<U21')
```

`char.join(sep, seq)`

Return a string which is the concatenation of the strings in the sequence *seq*.

Calls `str.join` element-wise.

Parameters

sep

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

seq

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

Returns

out

[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.join`

Examples

```
>>> import numpy as np
>>> np.strings.join('-', 'osd')
array('o-s-d', dtype='<U5')
```

```
>>> np.strings.join(['-', '.'], ['ghc', 'osd'])
array(['g-h-c', 'o.s.d'], dtype='<U5')
```

`char.ljust(a, width, fillchar='')`

Return an array with the elements of *a* left-justified in a string of length *width*.

Parameters

a

[array-like, with StringDType, bytes_, or str_ dtype]

width

[array_like, with any integer dtype] The length of the resulting strings, unless `width < str_len(a)`.

fillchar

[array-like, with StringDType, bytes_, or str_ dtype] Optional character to use for padding (default is space).

Returns

out

[ndarray] Output array of StringDType, bytes_ or str_ dtype, depending on input types

See also:

[`str.ljust`](#)

Notes

While it is possible for *a* and *fillchar* to have different dtypes, passing a non-ASCII character in *fillchar* when *a* is of dtype “S” is not allowed, and a `ValueError` is raised.

Examples

```
>>> import numpy as np
>>> c = np.array(['aAaAa', ' aA ', 'abBABba'])
>>> np.strings.ljust(c, width=3)
array(['aAaAa', ' aA ', 'abBABba'], dtype='<U7')
>>> np.strings.ljust(c, width=9)
array(['aAaAa', ' aA ', 'abBABba'], dtype='<U9')
```

`char.lower(a)`

Return an array with the elements converted to lowercase.

Call `str.lower` element-wise.

For 8-bit strings, this method is locale-dependent.

Parameters

a
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array.

Returns

out
[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.lower`

Examples

```
>>> import numpy as np
>>> c = np.array(['A1B C', '1BCA', 'BCA1']); c
array(['A1B C', '1BCA', 'BCA1'], dtype='<U5')
>>> np.strings.lower(c)
array(['a1b c', '1bca', 'bca1'], dtype='<U5')
```

`char.lstrip(a, chars=None)`

For each element in *a*, return a copy with the leading characters removed.

Parameters

a
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

chars
[scalar with the same dtype as *a*, optional] The *chars* argument is a string specifying the set of characters to be removed. If *None*, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped.

Returns

out
[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.lstrip`

Examples

```
>>> import numpy as np
>>> c = np.array(['aAaAa', ' aA ', 'abBABba'])
>>> c
array(['aAaAa', ' aA ', 'abBABba'], dtype='<U7')
# The 'a' variable is unstripped from c[1] because of leading whitespace.
>>> np.strings.lstrip(c, 'a')
array(['AaAaA', ' aA ', 'bBABba'], dtype='<U7')
>>> np.strings.lstrip(c, 'A') # leaves c unchanged
array(['aAaAa', ' aA ', 'abBABba'], dtype='<U7')
>>> (np.strings.lstrip(c, ' ') == np.strings.lstrip(c, '')).all()
np.False_
```

(continues on next page)

(continued from previous page)

```
>>> (np.strings.lstrip(c, ' ') == np.strings.lstrip(c)).all()
np.True_
```

`char.partition(a, sep)`

Partition each element in *a* around *sep*.

Calls `str.partition` element-wise.

For each element in *a*, split the element at the first occurrence of *sep*, and return 3 strings containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 strings containing the string itself, followed by two empty strings.

Parameters

a
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array

sep
[{`str`, `unicode`}] Separator to split each string element in *a*.

Returns

out
[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types. The output array will have an extra dimension with 3 elements per input element.

See also:

`str.partition`

Examples

```
>>> import numpy as np
>>> x = np.array(["Numpy is nice!"])
>>> np.char.partition(x, " ")
array(['Numpy', ' ', 'is nice!'], dtype='<U8')
```

`char.replace(a, old, new, count=-1)`

For each element in *a*, return a copy of the string with occurrences of substring *old* replaced by *new*.

Parameters

a
[array_like, with `bytes_` or `str_ dtype`]

old, new
[array_like, with `bytes_` or `str_ dtype`]

count
[array_like, with `int_ dtype`] If the optional argument *count* is given, only the first *count* occurrences are replaced.

Returns

out
[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.replace`

Examples

```
>>> import numpy as np
>>> a = np.array(["That is a mango", "Monkeys eat mangos"])
>>> np.strings.replace(a, 'mango', 'banana')
array(['That is a banana', 'Monkeys eat bananas'], dtype='<U19')
```

```
>>> a = np.array(["The dish is fresh", "This is it"])
>>> np.strings.replace(a, 'is', 'was')
array(['The dwash was fresh', 'Thwas was it'], dtype='<U19')
```

`char.rjust` (*a*, *width*, *fillchar*=' ')

Return an array with the elements of *a* right-justified in a string of length *width*.

Parameters

a

[array-like, with StringDType, bytes_, or str_ dtype]

width

[array_like, with any integer dtype] The length of the resulting strings, unless `width < str_len(a)`.

fillchar

[array-like, with StringDType, bytes_, or str_ dtype] Optional padding character to use (default is space).

Returns

out

[ndarray] Output array of StringDType, bytes_ or str_ dtype, depending on input types

See also:

`str.rjust`

Notes

While it is possible for *a* and *fillchar* to have different dtypes, passing a non-ASCII character in *fillchar* when *a* is of dtype “S” is not allowed, and a `ValueError` is raised.

Examples

```
>>> import numpy as np
>>> a = np.array(['aAaAaA', ' aA ', 'abBABba'])
>>> np.strings.rjust(a, width=3)
array(['aAaAaA', ' aA ', 'abBABba'], dtype='<U7')
>>> np.strings.rjust(a, width=9)
array([' aAaAaA', ' aA ', ' abBABba'], dtype='<U9')
```

`char.rpartition(a, sep)`

Partition (split) each element around the right-most separator.

Calls `str.rpartition` element-wise.

For each element in *a*, split the element as the last occurrence of *sep*, and return 3 strings containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 strings containing the string itself, followed by two empty strings.

Parameters

- a**
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array
- sep**
[str or unicode] Right-most separator to split each element in array.

Returns

- out**
[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types. The output array will have an extra dimension with 3 elements per input element.

See also:

`str.rpartition`

Examples

```
>>> import numpy as np
>>> a = np.array(['aAaAaA', ' aA ', 'abBABba'])
>>> np.char.rpartition(a, 'A')
array([[ 'aAaAa', 'A', ''],
       [ ' a', 'A', ' '],
       [ 'abB', 'A', 'Bba']], dtype='<U5')
```

`char.rsplit(a, sep=None, maxsplit=None)`

For each element in *a*, return a list of the words in the string, using *sep* as the delimiter string.

Calls `str.split` element-wise.

Except for splitting from the right, *rsplit* behaves like *split*.

Parameters

- a**
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]
- sep**
[str or unicode, optional] If *sep* is not specified or *None*, any whitespace string is a separator.
- maxsplit**
[int, optional] If *maxsplit* is given, at most *maxsplit* splits are done, the rightmost ones.

Returns

- out**
[ndarray] Array of list objects

See also:

`str.split`, `str.rsplit`

Examples

```
>>> import numpy as np
>>> a = np.array(['aAaAaA', 'abBABba'])
>>> np.strings.rsplitt(a, 'A')
array([list(['a', 'a', 'a', '']),
       list(['abB', 'Bba'])], dtype=object)
```

`char.rstrip(a, chars=None)`

For each element in *a*, return a copy with the trailing characters removed.

Parameters

a

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

chars

[scalar with the same dtype as *a*, optional] The *chars* argument is a string specifying the set of characters to be removed. If *None*, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped.

Returns

out

[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.rstrip`

Examples

```
>>> import numpy as np
>>> c = np.array(['aAaAaA', 'abBABba'])
>>> c
array(['aAaAaA', 'abBABba'], dtype='<U7')
>>> np.strings.rstrip(c, 'a')
array(['aAaAaA', 'abBABb'], dtype='<U7')
>>> np.strings.rstrip(c, 'A')
array(['aAaAa', 'abBABba'], dtype='<U7')
```

`char.split(a, sep=None, maxsplit=None)`

For each element in *a*, return a list of the words in the string, using *sep* as the delimiter string.

Calls `str.split` element-wise.

Parameters

a

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

sep

[str or unicode, optional] If *sep* is not specified or *None*, any whitespace string is a separator.

maxsplit

[int, optional] If *maxsplit* is given, at most *maxsplit* splits are done.

Returns

out
[ndarray] Array of list objects

See also:

`str.split`, `rsplit`

Examples

```
>>> import numpy as np
>>> x = np.array("Numpy is nice!")
>>> np.strings.split(x, " ")
array(list(['Numpy', 'is', 'nice!']), dtype=object)
```

```
>>> np.strings.split(x, " ", 1)
array(list(['Numpy', 'is nice!']), dtype=object)
```

`char.splitlines(a, keepends=None)`

For each element in *a*, return a list of the lines in the element, breaking at line boundaries.

Calls `str.splitlines` element-wise.

Parameters

a
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

keepends
[bool, optional] Line breaks are not included in the resulting list unless `keepends` is given and true.

Returns

out
[ndarray] Array of list objects

See also:

`str.splitlines`

Examples

```
>>> np.char.splitlines("first line\nsecond line")
array(list(['first line', 'second line']), dtype=object)
>>> a = np.array(["first\nsecond", "third\nfourth"])
>>> np.char.splitlines(a)
array([list(['first', 'second']), list(['third', 'fourth'])], dtype=object)
```

`char.strip(a, chars=None)`

For each element in *a*, return a copy with the leading and trailing characters removed.

Parameters

a
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

chars

[scalar with the same dtype as a, optional] The `chars` argument is a string specifying the set of characters to be removed. If `None`, the `chars` argument defaults to removing whitespace. The `chars` argument is not a prefix or suffix; rather, all combinations of its values are stripped.

Returns**out**

[ndarray] Output array of `StringDType`, `bytes_` or `str_` dtype, depending on input types

See also:

`str.strip`

Examples

```
>>> import numpy as np
>>> c = np.array(['aAaAaA', '  aA  ', 'abBABba'])
>>> c
array(['aAaAaA', '  aA  ', 'abBABba'], dtype='<U7')
>>> np.strings.strip(c)
array(['aAaAaA', 'aA', 'abBABba'], dtype='<U7')
# 'a' unstripped from c[1] because of leading whitespace.
>>> np.strings.strip(c, 'a')
array(['AaAaA', '  aA  ', 'bBABb'], dtype='<U7')
# 'A' unstripped from c[1] because of trailing whitespace.
>>> np.strings.strip(c, 'A')
array(['aAaAa', '  aA  ', 'abBABba'], dtype='<U7')
```

`char.swapcase(a)`

Return element-wise a copy of the string with uppercase characters converted to lowercase and vice versa.

Calls `str.swapcase` element-wise.

For 8-bit strings, this method is locale-dependent.

Parameters**a**

[array-like, with `StringDType`, `bytes_`, or `str_` dtype] Input array.

Returns**out**

[ndarray] Output array of `StringDType`, `bytes_` or `str_` dtype, depending on input types

See also:

`str.swapcase`

Examples

```
>>> import numpy as np
>>> c=np.array(['a1B c', '1b Ca', 'b Ca1', 'cA1b'], 'S5'); c
array(['a1B c', '1b Ca', 'b Ca1', 'cA1b'],
      dtype='|S5')
>>> np.strings.swapcase(c)
array(['A1b C', '1B cA', 'B cA1', 'Ca1B'],
      dtype='|S5')
```

char.**title**(a)

Return element-wise title cased version of string or unicode.

Title case words start with uppercase characters, all remaining cased characters are lowercase.

Calls `str.title` element-wise.

For 8-bit strings, this method is locale-dependent.

Parameters

a

[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] Input array.

Returns

out

[ndarray] Output array of `StringDType`, `bytes_` or `str_ dtype`, depending on input types

See also:

`str.title`

Examples

```
>>> import numpy as np
>>> c=np.array(['a1b c', '1b ca', 'b ca1', 'ca1b'], 'S5'); c
array(['a1b c', '1b ca', 'b ca1', 'ca1b'],
      dtype='|S5')
>>> np.strings.title(c)
array(['A1B C', '1B Ca', 'B Ca1', 'Ca1B'],
      dtype='|S5')
```

char.**translate**(a, table, deletechars=None)

For each element in *a*, return a copy of the string where all characters occurring in the optional argument *deletechars* are removed, and the remaining characters have been mapped through the given translation table.

Calls `str.translate` element-wise.

Parameters

a

[array-like, with `bytes_` or `str_ dtype`]

table

[str of length 256]

deletechars

[str]

Returns**out**

[ndarray] Output array of str or unicode, depending on input type

See also:`str.translate`**Examples**

```
>>> import numpy as np
>>> a = np.array(['a1b c', '1bca', 'bca1'])
>>> table = a[0].maketrans('abc', '123')
>>> deletechars = ' '
>>> np.char.translate(a, table, deletechars)
array(['112 3', '1231', '2311'], dtype='<U5')
```

`char.upper(a)`

Return an array with the elements converted to uppercase.

Calls `str.upper` element-wise.

For 8-bit strings, this method is locale-dependent.

Parameters**a**

[array-like, with StringDType, bytes_, or str_ dtype] Input array.

Returns**out**

[ndarray] Output array of StringDType, bytes_ or str_ dtype, depending on input types

See also:`str.upper`**Examples**

```
>>> import numpy as np
>>> c = np.array(['a1b c', '1bca', 'bca1']); c
array(['a1b c', '1bca', 'bca1'], dtype='<U5')
>>> np.strings.upper(c)
array(['A1B C', '1BCA', 'BCA1'], dtype='<U5')
```

`char.zfill(a, width)`

Return the numeric string left-filled with zeros. A leading sign prefix (+/-) is handled by inserting the padding after the sign character rather than before.

Parameters**a**

[array-like, with StringDType, bytes_, or str_ dtype]

width

[array_like, with any integer dtype] Width of string to left-fill elements in *a*.

Returns**out**

[ndarray] Output array of `StringDType`, `bytes_` or `str_` dtype, depending on input type

See also:

`str.zfill`

Examples

```
>>> import numpy as np
>>> np.strings.zfill(['1', '-1', '+1'], 3)
array(['001', '-01', '+01'], dtype='<U3')
```

Comparison

Unlike the standard numpy comparison operators, the ones in the *char* module strip trailing whitespace characters before performing the comparison.

<code>equal(x1, x2)</code>	Return $(x1 == x2)$ element-wise.
<code>not_equal(x1, x2)</code>	Return $(x1 != x2)$ element-wise.
<code>greater_equal(x1, x2)</code>	Return $(x1 \geq x2)$ element-wise.
<code>less_equal(x1, x2)</code>	Return $(x1 \leq x2)$ element-wise.
<code>greater(x1, x2)</code>	Return $(x1 > x2)$ element-wise.
<code>less(x1, x2)</code>	Return $(x1 < x2)$ element-wise.
<code>compare_chararrays(a1, a2, cmp, rstrip)</code>	Performs element-wise comparison of two string arrays using the comparison operator specified by <i>cmp</i> .

`char.equal(x1, x2)`

Return $(x1 == x2)$ element-wise.

Unlike `numpy.equal`, this comparison is performed by first stripping whitespace characters from the end of the string. This behavior is provided for backward-compatibility with `numarray`.

Parameters**x1, x2**

[array_like of str or unicode] Input arrays of the same shape.

Returns**out**

[ndarray] Output array of bools.

See also:

`not_equal`, `greater_equal`, `less_equal`, `greater`, `less`

Examples

```
>>> import numpy as np
>>> y = "aa "
>>> x = "aa"
>>> np.char.equal(x, y)
array(True)
```

`char.not_equal(x1, x2)`

Return $(x1 \neq x2)$ element-wise.

Unlike `numpy.not_equal`, this comparison is performed by first stripping whitespace characters from the end of the string. This behavior is provided for backward-compatibility with `numarray`.

Parameters

x1, x2

[array_like of str or unicode] Input arrays of the same shape.

Returns

out

[ndarray] Output array of bools.

See also:

[equal](#), [greater_equal](#), [less_equal](#), [greater](#), [less](#)

Examples

```
>>> import numpy as np
>>> x1 = np.array(['a', 'b', 'c'])
>>> np.char.not_equal(x1, 'b')
array([ True, False,  True])
```

`char.greater_equal(x1, x2)`

Return $(x1 \geq x2)$ element-wise.

Unlike `numpy.greater_equal`, this comparison is performed by first stripping whitespace characters from the end of the string. This behavior is provided for backward-compatibility with `numarray`.

Parameters

x1, x2

[array_like of str or unicode] Input arrays of the same shape.

Returns

out

[ndarray] Output array of bools.

See also:

[equal](#), [not_equal](#), [less_equal](#), [greater](#), [less](#)

Examples

```
>>> import numpy as np
>>> x1 = np.array(['a', 'b', 'c'])
>>> np.char.greater_equal(x1, 'b')
array([False,  True,  True])
```

`char.less_equal(x1, x2)`

Return $(x1 \leq x2)$ element-wise.

Unlike `numpy.less_equal`, this comparison is performed by first stripping whitespace characters from the end of the string. This behavior is provided for backward-compatibility with `numarray`.

Parameters

x1, x2

[array_like of str or unicode] Input arrays of the same shape.

Returns

out

[ndarray] Output array of bools.

See also:

[`equal`](#), [`not\_equal`](#), [`greater\_equal`](#), [`greater`](#), [`less`](#)

Examples

```
>>> import numpy as np
>>> x1 = np.array(['a', 'b', 'c'])
>>> np.char.less_equal(x1, 'b')
array([ True,  True, False])
```

`char.greater(x1, x2)`

Return $(x1 > x2)$ element-wise.

Unlike `numpy.greater`, this comparison is performed by first stripping whitespace characters from the end of the string. This behavior is provided for backward-compatibility with `numarray`.

Parameters

x1, x2

[array_like of str or unicode] Input arrays of the same shape.

Returns

out

[ndarray] Output array of bools.

See also:

[`equal`](#), [`not\_equal`](#), [`greater\_equal`](#), [`less\_equal`](#), [`less`](#)

Examples

```
>>> import numpy as np
>>> x1 = np.array(['a', 'b', 'c'])
>>> np.char.greater(x1, 'b')
array([False, False,  True])
```

`char.less(x1, x2)`

Return $(x1 < x2)$ element-wise.

Unlike `numpy.greater`, this comparison is performed by first stripping whitespace characters from the end of the string. This behavior is provided for backward-compatibility with `numarray`.

Parameters

x1, x2

[array_like of str or unicode] Input arrays of the same shape.

Returns

out

[ndarray] Output array of bools.

See also:

`equal`, `not_equal`, `greater_equal`, `less_equal`, `greater`

Examples

```
>>> import numpy as np
>>> x1 = np.array(['a', 'b', 'c'])
>>> np.char.less(x1, 'b')
array([ True, False, False])
```

`char.compare_chararrays(a1, a2, cmp, rstrip)`

Performs element-wise comparison of two string arrays using the comparison operator specified by `cmp`.

Parameters

a1, a2

[array_like] Arrays to be compared.

cmp

[["<", "<=", "==", ">=", ">", "!="]] Type of comparison.

rstrip

[bool] If True, the spaces at the end of strings are removed before the comparison.

Returns

out

[ndarray] The output array of type `numpy.bool` with the same shape as `a1` and `a2`.

Raises

ValueError

If `cmp` is not valid.

TypeError

If at least one of `a1` or `a2` is a non-string array

Examples

```
>>> import numpy as np
>>> a = np.array(["a", "b", "cde"])
>>> b = np.array(["a", "a", "dec"])
>>> np.char.compare_chararrays(a, b, ">", True)
array([False,  True, False])
```

String information

<code>count(a, sub[, start, end])</code>	Returns an array with the number of non-overlapping occurrences of substring <code>sub</code> in the range <code>[start, end)</code> .
<code>endswith(a, suffix[, start, end])</code>	Returns a boolean array which is <code>True</code> where the string element in <code>a</code> ends with <code>suffix</code> , otherwise <code>False</code> .
<code>find(a, sub[, start, end])</code>	For each element, return the lowest index in the string where substring <code>sub</code> is found, such that <code>sub</code> is contained in the range <code>[start, end)</code> .
<code>index(a, sub[, start, end])</code>	Like <code>find</code> , but raises <code>ValueError</code> when the substring is not found.
<code>isalpha(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if all characters in the data interpreted as a string are alphabetic and there is at least one character, false otherwise.
<code>isalnum(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if all characters in the string are alphanumeric and there is at least one character, false otherwise.
<code>isdecimal(x, /[, out, where, casting, ...])</code>	For each element, return <code>True</code> if there are only decimal characters in the element.
<code>isdigit(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if all characters in the string are digits and there is at least one character, false otherwise.
<code>islower(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if all cased characters in the string are lowercase and there is at least one cased character, false otherwise.
<code>isnumeric(x, /[, out, where, casting, ...])</code>	For each element, return <code>True</code> if there are only numeric characters in the element.
<code>isspace(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if there are only whitespace characters in the string and there is at least one character, false otherwise.
<code>istitle(x, /[, out, where, casting, order, ...])</code>	Returns true for each element if the element is a titlecased string and there is at least one character, false otherwise.
<code>isupper(x, /[, out, where, casting, order, ...])</code>	Return true for each element if all cased characters in the string are uppercase and there is at least one character, false otherwise.
<code>rfind(a, sub[, start, end])</code>	For each element, return the highest index in the string where substring <code>sub</code> is found, such that <code>sub</code> is contained in the range <code>[start, end)</code> .
<code>rindex(a, sub[, start, end])</code>	Like <code>rfind</code> , but raises <code>ValueError</code> when the substring <code>sub</code> is not found.
<code>startswith(a, prefix[, start, end])</code>	Returns a boolean array which is <code>True</code> where the string element in <code>a</code> starts with <code>prefix</code> , otherwise <code>False</code> .
<code>str_len(x, /[, out, where, casting, order, ...])</code>	Returns the length of each element.

`char.count(a, sub, start=0, end=None)`

Returns an array with the number of non-overlapping occurrences of substring `sub` in the range `[start, end)`.

Parameters

- a**
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]
- sub**
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] The substring to search for.
- start, end**
[array_like, with any integer dtype] The range to look in, interpreted as in slice notation.

Returns

- y**
[ndarray] Output array of ints

See also:

`str.count`

Examples

```
>>> import numpy as np
>>> c = np.array(['aAaAaA', '  aA  ', 'abBABba'])
>>> c
array(['aAaAaA', '  aA  ', 'abBABba'], dtype='<U7')
>>> np.strings.count(c, 'A')
array([3, 1, 1])
>>> np.strings.count(c, 'aA')
array([3, 1, 0])
>>> np.strings.count(c, 'A', start=1, end=4)
array([2, 1, 1])
>>> np.strings.count(c, 'A', start=1, end=3)
array([1, 0, 0])
```

`char.endswith(a, suffix, start=0, end=None)`

Returns a boolean array which is *True* where the string element in `a` ends with `suffix`, otherwise *False*.

Parameters

- a**
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]
- suffix**
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]
- start, end**
[array_like, with any integer dtype] With `start`, test beginning at that position. With `end`, stop comparing at that position.

Returns

- out**
[ndarray] Output array of bools

See also:

`str.endswith`

Examples

```
>>> import numpy as np
>>> s = np.array(['foo', 'bar'])
>>> s
array(['foo', 'bar'], dtype='<U3')
>>> np.strings.endswith(s, 'ar')
array([False,  True])
>>> np.strings.endswith(s, 'a', start=1, end=2)
array([False,  True])
```

`char.find(a, sub, start=0, end=None)`

For each element, return the lowest index in the string where substring `sub` is found, such that `sub` is contained in the range `[start, end)`.

Parameters

- a**
[array_like, with StringDType, bytes_ or str_ dtype]
- sub**
[array_like, with bytes_ or str_ dtype] The substring to search for.
- start, end**
[array_like, with any integer dtype] The range to look in, interpreted as in slice notation.

Returns

- y**
[ndarray] Output array of ints

See also:

`str.find`

Examples

```
>>> import numpy as np
>>> a = np.array(["NumPy is a Python library"])
>>> np.strings.find(a, "Python")
array([11])
```

`char.index(a, sub, start=0, end=None)`

Like `find`, but raises `ValueError` when the substring is not found.

Parameters

- a**
[array-like, with StringDType, bytes_, or str_ dtype]
- sub**
[array-like, with StringDType, bytes_, or str_ dtype]
- start, end**
[array_like, with any integer dtype, optional]

Returns

- out**
[ndarray] Output array of ints.

See also:

[`find`](#), [`str.index`](#)

Examples

```
>>> import numpy as np
>>> a = np.array(["Computer Science"])
>>> np.strings.index(a, "Science", start=0, end=None)
array([9])
```

`char.isalpha`(*x*, /, *out*=None, *, *where*=True, *casting*='same_kind', *order*='K', *dtype*=None, *subok*=True[, *signature*]) = <ufunc 'isalpha'>

Returns true for each element if all characters in the data interpreted as a string are alphabetic and there is at least one character, false otherwise.

For byte strings (i.e. `bytes`), alphabetic characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'`. For Unicode strings, alphabetic characters are those characters defined in the Unicode character database as “Letter”.

Parameters

x

[array_like, with `StringDType`, `bytes_`, or `str_ dtype`]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out*=None, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [*ufunc docs*](#).

Returns

y

[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

[`str.isalpha`](#)

Examples

```
>>> import numpy as np
>>> a = np.array(['a', 'b', '0'])
>>> np.strings.isalpha(a)
array([ True,  True, False])
```

```
>>> a = np.array([[ 'a', 'b', '0'], [ 'c', '1', '2']])
>>> np.strings.isalpha(a)
array([[ True,  True, False], [ True, False, False]])
```

`char.isalnum`(*x*, /, *out*=None, *, *where*=True, *casting*='same_kind', *order*='K', *dtype*=None, *subok*=True[, *signature*]) = <ufunc 'isalnum'>

Returns true for each element if all characters in the string are alphanumeric and there is at least one character, false otherwise.

Parameters

x

[array_like, with StringDType, bytes_ or str_ dtype]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out*=None, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray] Output array of bool This is a scalar if *x* is a scalar.

See also:

[str.isalnum](#)

Examples

```
>>> import numpy as np
>>> a = np.array(['a', '1', 'a1', '(', ''])
>>> np.strings.isalnum(a)
array([ True,  True,  True, False, False])
```

`char.isdecimal`(*x*, /, *out*=None, *, *where*=True, *casting*='same_kind', *order*='K', *dtype*=None, *subok*=True[, *signature*]) = <ufunc 'isdecimal'>

For each element, return True if there are only decimal characters in the element.

Decimal characters include digit characters, and all characters that can be used to form decimal-radix numbers, e.g. U+0660, ARABIC-INDIC DIGIT ZERO.

Parameters

x
[array_like, with StringDType or str_ dtype]

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where
[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**
For other keyword-only arguments, see the [ufunc docs](#).

Returns

y
[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

[str.isdecimal](#)

Examples

```
>>> import numpy as np
>>> np.strings.isdecimal(['12345', '4.99', '123ABC', ''])
array([ True, False, False, False])
```

`char.isdigit(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'isdigit'>`

Returns true for each element if all characters in the string are digits and there is at least one character, false otherwise.

For byte strings, digits are the byte values in the sequence b'0123456789'. For Unicode strings, digits include decimal characters and digits that need special handling, such as the compatibility superscript digits. This also covers digits which cannot be used to form numbers in base 10, like the Kharosthi numbers.

Parameters

x
[array_like, with StringDType, bytes_, or str_ dtype]

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

y

[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.isdigit`

Examples

```
>>> import numpy as np
>>> a = np.array(['a', 'b', '0'])
>>> np.strings.isdigit(a)
array([False, False,  True])
>>> a = np.array(['a', 'b', '0'], ['c', '1', '2'])
>>> np.strings.isdigit(a)
array([[False, False,  True], [False,  True,  True]])
```

`char.islower`(*x*, /, *out=None*, *, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True* [, *signature*]) = <ufunc 'islower'>

Returns true for each element if all cased characters in the string are lowercase and there is at least one cased character, false otherwise.

Parameters

x

[array_like, with StringDType, bytes_ or str_ dtype]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

out

[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.islower`

Examples

```
>>> import numpy as np
>>> np.strings.islower("GHC")
array(False)
>>> np.strings.islower("ghc")
array(True)
```

`char.isnumeric`(*x*, */*, *out=None*, ***, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True*[, *signature*]) = `<ufunc 'isnumeric'>`

For each element, return True if there are only numeric characters in the element.

Numeric characters include digit characters, and all characters that have the Unicode numeric value property, e.g. U+2155, VULGAR FRACTION ONE FIFTH.

Parameters

x
[array_like, with `StringDType` or `str_ dtype`]

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where
[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**
For other keyword-only arguments, see the [ufunc docs](#).

Returns

y
[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.isnumeric`

Examples

```
>>> import numpy as np
>>> np.strings.isnumeric(['123', '123abc', '9.0', '1/4', 'VIII'])
array([ True, False, False, False, False])
```

`char.isspace`(*x*, */*, *out=None*, ***, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True*[, *signature*]) = `<ufunc 'isspace'>`

Returns true for each element if there are only whitespace characters in the string and there is at least one character, false otherwise.

For byte strings, whitespace characters are the ones in the sequence `b' tnrx0bf'`. For Unicode strings, a character is whitespace, if, in the Unicode character database, its general category is Zs (“Separator, space”), or its bidirectional class is one of WS, B, or S.

Parameters

x

[array_like, with `StringDType`, `bytes_`, or `str_ dtype`]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

y

[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.isspace`

Examples

```
>>> np.char.isspace(list("a b c"))
array([False,  True, False,  True, False])
>>> np.char.isspace(b'\x0a \x0b \x0c')
np.True_
>>> np.char.isspace(b'\x0a \x0b \x0c N')
np.False_
```

`char.istitle`(*x*, /, *out=None*, *, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True*[, *signature*]) = <ufunc 'istitle'>

Returns true for each element if the element is a titlecased string and there is at least one character, false otherwise.

Parameters

x

[array_like, with `StringDType`, `bytes_` or `str_ dtype`]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**out**

[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.istitle`

Examples

```
>>> import numpy as np
>>> np.strings.istitle("Numpy Is Great")
array(True)
```

```
>>> np.strings.istitle("Numpy is great")
array(False)
```

`char.issupper` (*x*, /, *out=None*, *, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True* [, *signature*]) = <ufunc 'issupper'>

Return true for each element if all cased characters in the string are uppercase and there is at least one character, false otherwise.

Parameters**x**

[array_like, with `StringDType`, `bytes_` or `str_` dtype]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**out**

[ndarray] Output array of bools This is a scalar if *x* is a scalar.

See also:

`str.isupper`

Examples

```
>>> import numpy as np
>>> np.strings.isupper("GHC")
array(True)
>>> a = np.array(["hello", "HELLO", "Hello"])
>>> np.strings.isupper(a)
array([False,  True, False])
```

`char.rfind(a, sub, start=0, end=None)`

For each element, return the highest index in the string where substring `sub` is found, such that `sub` is contained in the range `[start, end)`.

Parameters

a[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]**sub**[array-like, with `StringDType`, `bytes_`, or `str_ dtype`] The substring to search for.**start, end**

[array_like, with any integer dtype] The range to look in, interpreted as in slice notation.

Returns

y

[ndarray] Output array of ints

See also:`str.rfind`

Examples

```
>>> import numpy as np
>>> a = np.array(["Computer Science"])
>>> np.strings.rfind(a, "Science", start=0, end=None)
array([9])
>>> np.strings.rfind(a, "Science", start=0, end=8)
array([-1])
>>> b = np.array(["Computer Science", "Science"])
>>> np.strings.rfind(b, "Science", start=0, end=None)
array([9, 0])
```

`char.rindex(a, sub, start=0, end=None)`

Like `rfind`, but raises `ValueError` when the substring `sub` is not found.

Parameters

a[array-like, with `bytes_` or `str_ dtype`]**sub**[array-like, with `bytes_` or `str_ dtype`]

start, end
[array-like, with any integer dtype, optional]

Returns

out
[ndarray] Output array of ints.

See also:

[`rfind`](#), [`str.rindex`](#)

Examples

```
>>> a = np.array(["Computer Science"])
>>> np.strings.rindex(a, "Science", start=0, end=None)
array([9])
```

`char.startswith(a, prefix, start=0, end=None)`

Returns a boolean array which is *True* where the string element in `a` starts with `prefix`, otherwise *False*.

Parameters

a
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

prefix
[array-like, with `StringDType`, `bytes_`, or `str_ dtype`]

start, end
[array_like, with any integer dtype] With `start`, test beginning at that position. With `end`, stop comparing at that position.

Returns

out
[ndarray] Output array of bools

See also:

[`str.startswith`](#)

Examples

```
>>> import numpy as np
>>> s = np.array(['foo', 'bar'])
>>> s
array(['foo', 'bar'], dtype='<U3')
>>> np.strings.startswith(s, 'fo')
array([True, False])
>>> np.strings.startswith(s, 'o', start=1, end=2)
array([True, False])
```

`char.str_len(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'str_len'>`

Returns the length of each element. For byte strings, this is the number of bytes, while, for Unicode strings, it is the number of Unicode code points.

Parameters**x**[array_like, with `StringDType`, `bytes_`, or `str_ dtype`]**out**

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.****kwargs**For other keyword-only arguments, see the [ufunc docs](#).**Returns****y**[ndarray] Output array of ints This is a scalar if *x* is a scalar.**See also:**[len](#)**Examples**

```

>>> import numpy as np
>>> a = np.array(['Grace Hopper Conference', 'Open Source Day'])
>>> np.strings.str_len(a)
array([23, 15])
>>> a = np.array(['P', 'o'])
>>> np.strings.str_len(a)
array([1, 1])
>>> a = np.array(['hello', 'world'], ['P', 'o'])
>>> np.strings.str_len(a)
array([[5, 5], [1, 1]])

```

Convenience class

<code>array(obj[, itemsize, copy, unicode, order])</code>	Create a chararray .
<code>asarray(obj[, itemsize, unicode, order])</code>	Convert the input to a chararray , copying the data only if necessary.
<code>chararray(shape[, itemsize, unicode, ...])</code>	Provides a convenient view on arrays of string and unicode values.

`char.array (obj, itemsize=None, copy=True, unicode=None, order=None)`

Create a [chararray](#).

Deprecated since version 2.5: `chararray` is deprecated. Use an `ndarray` with a string or bytes dtype instead.

Note: This class is provided for `numarray` backward-compatibility. New code (not concerned with `numarray` compatibility) should use arrays of type `bytes_` or `str_` and use the free functions in `numpy.char` for fast vectorized string operations instead.

Versus a NumPy array of dtype `bytes_` or `str_`, this class adds the following functionality:

- 1) values automatically have whitespace removed from the end when indexed
- 2) comparison operators automatically remove whitespace from the end when comparing values
- 3) vectorized string operations are provided as methods (e.g. `chararray.endswith`) and infix operators (e.g. `+`, `*`, `%`)

Parameters

obj

[array of str or unicode-like]

itemsize

[int, optional] *itemsize* is the number of characters per scalar in the resulting array. If *itemsize* is None, and *obj* is an object array or a Python list, the *itemsize* will be automatically determined. If *itemsize* is provided and *obj* is of type str or unicode, then the *obj* string will be chunked into *itemsize* pieces.

copy

[bool, optional] If true (default), then the object is copied. Otherwise, a copy will only be made if `__array__` returns a copy, if *obj* is a nested sequence, or if a copy is needed to satisfy any of the other requirements (*itemsize*, *unicode*, *order*, etc.).

unicode

[bool, optional] When true, the resulting `chararray` can contain Unicode characters, when false only 8-bit characters. If *unicode* is None and *obj* is one of the following:

- a `chararray`,
- an ndarray of type `str_` or `bytes_`
- a Python `str` or `bytes` object,

then the *unicode* setting of the output array will be automatically determined.

order

[{'C', 'F', 'A'}, optional] Specify the order of the array. If order is 'C' (default), then the array will be in C-contiguous order (last-index varies the fastest). If order is 'F', then the returned array will be in Fortran-contiguous order (first-index varies the fastest). If order is 'A', then the returned array may be in any order (either C-, Fortran-contiguous, or even discontinuous).

Examples

```
>>> import numpy as np
>>> char_array = np.char.array(['hello', 'world', 'numpy', 'array'])
>>> char_array
chararray(['hello', 'world', 'numpy', 'array'], dtype='<U5')
```

`char.asarray` (*obj*, *itemsize=None*, *unicode=None*, *order=None*)

Convert the input to a `chararray`, copying the data only if necessary.

Deprecated since version 2.5: `chararray` is deprecated. Use an ndarray with a string or bytes dtype instead.

Versus a NumPy array of dtype `bytes_` or `str_`, this class adds the following functionality:

- 1) values automatically have whitespace removed from the end when indexed
- 2) comparison operators automatically remove whitespace from the end when comparing values
- 3) vectorized string operations are provided as methods (e.g. `chararray.endswith`) and infix operators (e.g. `+`, `*`, `%`)

Parameters

obj

[array of str or unicode-like]

itemsize

[int, optional] *itemsize* is the number of characters per scalar in the resulting array. If *itemsize* is None, and *obj* is an object array or a Python list, the *itemsize* will be automatically determined. If *itemsize* is provided and *obj* is of type str or unicode, then the *obj* string will be chunked into *itemsize* pieces.

unicode

[bool, optional] When true, the resulting `chararray` can contain Unicode characters, when false only 8-bit characters. If unicode is None and *obj* is one of the following:

- a `chararray`,
- an ndarray of type `str_` or `unicode_`
- a Python str or unicode object,

then the unicode setting of the output array will be automatically determined.

order

[{'C', 'F'}, optional] Specify the order of the array. If order is 'C' (default), then the array will be in C-contiguous order (last-index varies the fastest). If order is 'F', then the returned array will be in Fortran-contiguous order (first-index varies the fastest).

Examples

```
>>> import numpy as np
>>> np.char.asarray(['hello', 'world'])
chararray(['hello', 'world'], dtype='<U5')
```

class `numpy.char.chararray` (*shape*, *itemsize=1*, *unicode=False*, *buffer=None*, *offset=0*, *strides=None*, *order=None*)

Provides a convenient view on arrays of string and unicode values.

Deprecated since version 2.5: `chararray` is deprecated. Use an `ndarray` with a string or bytes dtype instead.

Note: The `chararray` class exists for backwards compatibility with Numarray, it is not recommended for new development. Starting from numpy 1.4, if one needs arrays of strings, it is recommended to use arrays of dtype `object_`, `bytes_` or `str_`, and use the free functions in the `numpy.char` module for fast vectorized string operations.

Versus a NumPy array of dtype `bytes_` or `str_`, this class adds the following functionality:

- 1) values automatically have whitespace removed from the end when indexed
- 2) comparison operators automatically remove whitespace from the end when comparing values

- 3) vectorized string operations are provided as methods (e.g. `endswith`) and infix operators (e.g. `"+"`, `"*"`, `"%"`)

chararrays should be created using `numpy.char.array` or `numpy.char.asarray`, rather than this constructor directly.

This constructor creates the array, using `buffer` (with `offset` and `strides`) if it is not `None`. If `buffer` is `None`, then constructs a new array with `strides` in “C order”, unless both `len(shape) >= 2` and `order='F'`, in which case `strides` is in “Fortran order”.

Parameters

shape

[tuple] Shape of the array.

itemsize

[int, optional] Length of each array element, in number of characters. Default is 1.

unicode

[bool, optional] Are the array elements of type unicode (True) or string (False). Default is False.

buffer

[object exposing the buffer interface or str, optional] Memory address of the start of the array data. Default is `None`, in which case a new array is created.

offset

[int, optional] Fixed stride displacement from the beginning of an axis? Default is 0. Needs to be ≥ 0 .

strides

[array_like of ints, optional] Strides for the array (see `strides` for full description). Default is `None`.

order

[{'C', 'F'}, optional] The order in which the array data is stored in memory: 'C' -> “row major” order (the default), 'F' -> “column major” (Fortran) order.

Attributes

T

View of the transposed array.

base

Base object if memory is from some other object.

ctypes

An object to simplify the interaction of the array with the `ctypes` module.

data

Python buffer object pointing to the start of the array’s data.

device

dtype

Data-type of the array’s elements.

flags

Information about the memory layout of the array.

flat

A 1-D iterator over the array.

imag	The imaginary part of the array.
itemsize	Length of one array element in bytes.
mT	View of the matrix transposed array.
nbytes	Total bytes consumed by the elements of the array.
ndim	Number of array dimensions.
real	The real part of the array.
shape	Tuple of array dimensions.
size	Number of elements in the array.
strides	Tuple of bytes to step in each dimension when traversing an array.

Methods

<code>astype(dtype[, order, casting, subok, copy])</code>	Copy of the array, cast to a specified type.
<code>argsort([axis, kind, order, stable, descending])</code>	Returns the indices that would sort this array.
<code>copy([order])</code>	Return a copy of the array.
<code>count(sub[, start, end])</code>	Returns an array with the number of non-overlapping occurrences of substring <i>sub</i> in the range <i>[start, end]</i> .
<code>decode([encoding, errors])</code>	Calls <code>bytes.decode</code> element-wise.
<code>dump(file)</code>	Dump a pickle of the array to the specified file.
<code>dumps()</code>	Returns the pickle of the array as a string.
<code>encode([encoding, errors])</code>	Calls <code>str.encode</code> element-wise.
<code>endswith(suffix[, start, end])</code>	Returns a boolean array which is <i>True</i> where the string element in <i>self</i> ends with <i>suffix</i> , otherwise <i>False</i> .
<code>expandtabs([tabsize])</code>	Return a copy of each string element where all tab characters are replaced by one or more spaces.
<code>fill(value)</code>	Fill the array with a scalar value.
<code>find(sub[, start, end])</code>	For each element, return the lowest index in the string where substring <i>sub</i> is found.
<code>flatten([order])</code>	Return a copy of the array collapsed into one dimension.
<code>getfield(dtype[, offset])</code>	Returns a field of the given array as a certain type.
<code>index(sub[, start, end])</code>	Like <code>find</code> , but raises <code>ValueError</code> when the substring is not found.
<code>isalnum()</code>	Returns true for each element if all characters in the string are alphanumeric and there is at least one character, false otherwise.

continues on next page

Table 4 – continued from previous page

<code>isalpha()</code>	Returns true for each element if all characters in the string are alphabetic and there is at least one character, false otherwise.
<code>isdecimal()</code>	For each element in <i>self</i> , return True if there are only decimal characters in the element.
<code>isdigit()</code>	Returns true for each element if all characters in the string are digits and there is at least one character, false otherwise.
<code>islower()</code>	Returns true for each element if all cased characters in the string are lowercase and there is at least one cased character, false otherwise.
<code>isnumeric()</code>	For each element in <i>self</i> , return True if there are only numeric characters in the element.
<code>isspace()</code>	Returns true for each element if there are only white-space characters in the string and there is at least one character, false otherwise.
<code>istitle()</code>	Returns true for each element if the element is a title-cased string and there is at least one character, false otherwise.
<code>isupper()</code>	Returns true for each element if all cased characters in the string are uppercase and there is at least one character, false otherwise.
<code>item(*args)</code>	Copy an element of an array to a standard Python scalar and return it.
<code>join(seq)</code>	Return a string which is the concatenation of the strings in the sequence <i>seq</i> .
<code>ljust(width[, fillchar])</code>	Return an array with the elements of <i>self</i> left-justified in a string of length <i>width</i> .
<code>lower()</code>	Return an array with the elements of <i>self</i> converted to lowercase.
<code>lstrip([chars])</code>	For each element in <i>self</i> , return a copy with the leading characters removed.
<code>nonzero()</code>	Return the indices of the elements that are non-zero.
<code>put(indices, values[, mode])</code>	Set <code>a.flat[n] = values[n]</code> for all <i>n</i> in indices.
<code>ravel([order])</code>	Return a flattened array.
<code>repeat(repeats[, axis])</code>	Repeat elements of an array.
<code>replace(old, new[, count])</code>	For each element in <i>self</i> , return a copy of the string with all occurrences of substring <i>old</i> replaced by <i>new</i> .
<code>reshape(a.reshape)</code>	Returns an array containing the same data with a new shape.
<code>resize(a.resize)</code>	Change shape and size of array in-place.
<code>rfind(sub[, start, end])</code>	For each element in <i>self</i> , return the highest index in the string where substring <i>sub</i> is found, such that <i>sub</i> is contained within <i>[start, end]</i> .
<code>rindex(sub[, start, end])</code>	Like <code>rfind</code> , but raises <code>ValueError</code> when the substring <i>sub</i> is not found.
<code>rjust(width[, fillchar])</code>	Return an array with the elements of <i>self</i> right-justified in a string of length <i>width</i> .
<code>rsplit([sep, maxsplit])</code>	For each element in <i>self</i> , return a list of the words in the string, using <i>sep</i> as the delimiter string.
<code>rstrip([chars])</code>	For each element in <i>self</i> , return a copy with the trailing characters removed.

continues on next page

Table 4 – continued from previous page

<code>searchsorted(v[, side, sorter])</code>	Find indices where elements of <i>v</i> should be inserted in <i>a</i> to maintain order.
<code>setfield(val, dtype[, offset])</code>	Put a value into a specified place in a field defined by a data-type.
<code>setflags([write, align, uic])</code>	Set array flags WRITEABLE, ALIGNED, WRITEBACKIFCOPY, respectively.
<code>sort([axis, kind, order, stable, descending])</code>	Sort an array in-place.
<code>split([sep, maxsplit])</code>	For each element in <i>self</i> , return a list of the words in the string, using <i>sep</i> as the delimiter string.
<code>splitlines([keepends])</code>	For each element in <i>self</i> , return a list of the lines in the element, breaking at line boundaries.
<code>squeeze([axis])</code>	Remove axes of length one from <i>a</i> .
<code>startswith(prefix[, start, end])</code>	Returns a boolean array which is <i>True</i> where the string element in <i>self</i> starts with <i>prefix</i> , otherwise <i>False</i> .
<code>strip([chars])</code>	For each element in <i>self</i> , return a copy with the leading and trailing characters removed.
<code>swapaxes(axis1, axis2, /)</code>	Return a view of the array with <i>axis1</i> and <i>axis2</i> interchanged.
<code>swapcase()</code>	For each element in <i>self</i> , return a copy of the string with uppercase characters converted to lowercase and vice versa.
<code>take(indices[, axis, out, mode])</code>	Return an array formed from the elements of <i>a</i> at the given indices.
<code>title()</code>	For each element in <i>self</i> , return a titlecased version of the string: words start with uppercase characters, all remaining cased characters are lowercase.
<code>tofile(fid, /[, sep, format])</code>	Write array to a file as text or binary (default).
<code>tolist()</code>	Return the array as an <code>a.ndim</code> -levels deep nested list of Python scalars.
<code>translate(table[, deletechars])</code>	For each element in <i>self</i> , return a copy of the string where all characters occurring in the optional argument <i>deletechars</i> are removed, and the remaining characters have been mapped through the given translation table.
<code>transpose(*axes)</code>	Returns a view of the array with axes transposed.
<code>upper()</code>	Return an array with the elements of <i>self</i> converted to uppercase.
<code>view([dtype][, type])</code>	New view of array with the same data.
<code>zfill(width)</code>	Return the numeric string left-filled with zeros in a string of length <i>width</i> .

method

`char.chararray.astype (dtype, order='K', casting='unsafe', subok=True, copy=True)`

Copy of the array, cast to a specified type.

Parameters

dtype

[str or dtype] Typecode or data-type to which the array is cast.

order

[['C', 'F', 'A', 'K'], optional] Controls the memory layout order of the result. 'C' means C order, 'F' means Fortran order, 'A' means 'F' order if all the arrays are Fortran contiguous, 'C'

order otherwise, and 'K' means as close to the order the array elements appear in memory as possible. Default is 'K'.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'same_value', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility.

- 'no' means the data types should not be cast at all.
- 'equiv' means only byte-order changes are allowed.
- 'safe' means only casts which can preserve values are allowed.
- 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed.
- 'unsafe' means any data conversions may be done.
- 'same_value' means any data conversions may be done, but the values must not change, including rounding of floats or overflow of ints

New in version 2.4: Support for 'same_value' was added.

subok

[bool, optional] If True, then sub-classes will be passed-through (default), otherwise the returned array will be forced to be a base-class array.

copy

[bool, optional] By default, `astype` always returns a newly allocated array. If this is set to false, and the *dtype*, *order*, and *subok* requirements are satisfied, the input array is returned instead of a copy.

Returns**arr_t**

[ndarray] Unless *copy* is False and the other conditions for returning the input array are satisfied (see description for *copy* input parameter), *arr_t* is a new array of the same shape as the input array, with dtype, order given by *dtype*, *order*.

Raises**ComplexWarning**

When casting from complex to float or int. To avoid this, one should use `a.real.astype(t)`.

ValueError

When casting using 'same_value' and the values change or would overflow

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 2.5])
>>> x
array([1. ,  2. ,  2.5])
```

```
>>> x.astype(np.int_)
array([1,  2,  2])
```

```
>>> x.astype(np.int_, casting="same_value")
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: could not cast 'same_value' double to long
```

```
>>> x[:2].astype(np.int_, casting="same_value")
array([1, 2])
```

method

`char.chararray.argsort` (*axis=-1, kind=None, order=None, *, stable=None, descending=None*)

Returns the indices that would sort this array.

Refer to [numpy.argsort](#) for full documentation.

See also:

[numpy.argsort](#)
equivalent function

method

`char.chararray.copy` (*order='C'*)

Return a copy of the array.

Parameters

order

[{'C', 'F', 'A', 'K'}, optional] Controls the memory layout of the copy. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *a* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *a* as closely as possible. (Note that this function and [numpy.copy](#) are very similar but have different default values for their `order=` arguments, and this function always passes sub-classes through.)

See also:

[numpy.copy](#)
Similar function with different default behavior

[numpy.copyto](#)

Notes

This function is the preferred method for creating an array copy. The function [numpy.copy](#) is similar, but it defaults to using order 'K', and will not pass sub-classes through by default.

Examples

```
>>> import numpy as np
>>> x = np.array([[1,2,3],[4,5,6]], order='F')
```

```
>>> y = x.copy()
```

```
>>> x.fill(0)
```

```
>>> x
array([[0, 0, 0],
       [0, 0, 0]])
```

```
>>> y
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> y.flags['C_CONTIGUOUS']
True
```

For arrays containing Python objects (e.g. `dtype=np.object_`), the copy is a shallow one. The new array will contain the same object which may lead to surprises if that object can be modified (is mutable):

```
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> b = a.copy()
>>> b[2][0] = 10
>>> a
array([1, 'm', list([10, 3, 4])], dtype=object)
```

To ensure all elements within an object array are copied, use `copy.deepcopy`:

```
>>> import copy
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> c = copy.deepcopy(a)
>>> c[2][0] = 10
>>> c
array([1, 'm', list([10, 3, 4])], dtype=object)
>>> a
array([1, 'm', list([2, 3, 4])], dtype=object)
```

method

`char.chararray.count` (*sub*, *start*=0, *end*=None)

Returns an array with the number of non-overlapping occurrences of substring *sub* in the range [*start*, *end*].

See also:

[`char.count`](#)

method

`char.chararray.decode` (*encoding*=None, *errors*=None)

Calls `bytes.decode` element-wise.

See also:

[`char.decode`](#)

method

`char.chararray.dump` (*file*)

Dump a pickle of the array to the specified file. The array can be read back with `pickle.load` or `numpy.load`.

Parameters

file

[str or Path] A string naming the dump file.

method

`char.chararray.dumps()`

Returns the pickle of the array as a string. `pickle.loads` will convert the string back to an array.

Parameters

None

method

`char.chararray.encode(encoding=None, errors=None)`

Calls `str.encode` element-wise.

See also:

[`char.encode`](#)

method

`char.chararray.endswith(suffix, start=0, end=None)`

Returns a boolean array which is *True* where the string element in *self* ends with *suffix*, otherwise *False*.

See also:

[`char.endswith`](#)

method

`char.chararray.expandtabs(tabsize=8)`

Return a copy of each string element where all tab characters are replaced by one or more spaces.

See also:

[`char.expandtabs`](#)

method

`char.chararray.fill(value)`

Fill the array with a scalar value.

Parameters

value

[scalar] All elements of *a* will be assigned this value.

Examples

```
>>> import numpy as np
>>> a = np.array([1, 2])
>>> a.fill(0)
>>> a
array([0, 0])
>>> a = np.empty(2)
>>> a.fill(1)
>>> a
array([1., 1.])
```

Fill expects a scalar value and always behaves the same as assigning to a single array element. The following is a rare example where this distinction is important:

```
>>> a = np.array([None, None], dtype=np.object_)
>>> a[0] = np.array(3)
>>> a
array([array(3), None], dtype=object)
>>> a.fill(np.array(3))
>>> a
array([array(3), array(3)], dtype=object)
```

Where other forms of assignments will unpack the array being assigned:

```
>>> a[...] = np.array(3)
>>> a
array([3, 3], dtype=object)
```

method

`char.chararray.find` (*sub*, *start*=0, *end*=None)

For each element, return the lowest index in the string where substring *sub* is found.

See also:

[*char.find*](#)

method

`char.chararray.flatten` (*order*='C')

Return a copy of the array collapsed into one dimension.

Parameters

order

[['C', 'F', 'A', 'K'], optional] 'C' means to flatten in row-major (C-style) order. 'F' means to flatten in column-major (Fortran- style) order. 'A' means to flatten in column-major order if *a* is Fortran *contiguous* in memory, row-major order otherwise. 'K' means to flatten *a* in the order the elements occur in memory. The default is 'C'.

Returns

y

[ndarray] A copy of the input array, flattened to one dimension.

See also:

[*ravel*](#)

Return a flattened array.

flat

A 1-D flat iterator over the array.

Examples

```
>>> import numpy as np
>>> a = np.array([[1,2], [3,4]])
>>> a.flatten()
array([1, 2, 3, 4])
>>> a.flatten('F')
array([1, 3, 2, 4])
```

method

`char.chararray.getfield(dtype, offset=0)`

Returns a field of the given array as a certain type.

A field is a view of the array data with a given data-type. The values in the view are determined by the given type and the offset into the current array in bytes. The offset needs to be such that the view dtype fits in the array dtype; for example an array of dtype `complex128` has 16-byte elements. If taking a view with a 32-bit integer (4 bytes), the offset needs to be between 0 and 12 bytes.

Parameters

dtype

[str or dtype] The data type of the view. The dtype size of the view can not be larger than that of the array itself.

offset

[int] Number of bytes to skip before beginning the element view.

Examples

```
>>> import numpy as np
>>> x = np.diag([1.+1.j]*2)
>>> x[1, 1] = 2 + 4.j
>>> x
array([[1.+1.j,  0.+0.j],
       [0.+0.j,  2.+4.j]])
>>> x.getfield(np.float64)
array([[1.,  0.],
       [0.,  2.]])
```

By choosing an offset of 8 bytes we can select the complex part of the array for our view:

```
>>> x.getfield(np.float64, offset=8)
array([[1.,  0.],
       [0.,  4.]])
```

method

`char.chararray.index(sub, start=0, end=None)`

Like *find*, but raises `ValueError` when the substring is not found.

See also:

[*char.index*](#)

method

`char.chararray.isalnum()`

Returns true for each element if all characters in the string are alphanumeric and there is at least one character, false otherwise.

See also:

[char.isalnum](#)

method

`char.chararray.isalpha()`

Returns true for each element if all characters in the string are alphabetic and there is at least one character, false otherwise.

See also:

[char.isalpha](#)

method

`char.chararray.isdecimal()`

For each element in *self*, return True if there are only decimal characters in the element.

See also:

[char.isdecimal](#)

method

`char.chararray.isdigit()`

Returns true for each element if all characters in the string are digits and there is at least one character, false otherwise.

See also:

[char.isdigit](#)

method

`char.chararray.islower()`

Returns true for each element if all cased characters in the string are lowercase and there is at least one cased character, false otherwise.

See also:

[char.islower](#)

method

`char.chararray.isnumeric()`

For each element in *self*, return True if there are only numeric characters in the element.

See also:

[char.isnumeric](#)

method

`char.chararray.isspace()`

Returns true for each element if there are only whitespace characters in the string and there is at least one character, false otherwise.

See also:

`char.isspace`

method

`char.chararray.istitle()`

Returns true for each element if the element is a titlecased string and there is at least one character, false otherwise.

See also:

`char.istitle`

method

`char.chararray.isupper()`

Returns true for each element if all cased characters in the string are uppercase and there is at least one character, false otherwise.

See also:

`char.isupper`

method

`char.chararray.item(*args)`

Copy an element of an array to a standard Python scalar and return it.

Parameters

***args**

[Arguments (variable number and type)]

- `none`: in this case, the method only works for arrays with one element (`a.size == 1`), which element is copied into a standard Python scalar object and returned.
- `int_type`: this argument is interpreted as a flat index into the array, specifying which element to copy and return.
- `tuple of int_types`: functions as does a single `int_type` argument, except that the argument is interpreted as an nd-index into the array.

Returns

z

[Standard Python scalar object] A copy of the specified element of the array as a suitable Python scalar

Notes

When the data type of *a* is `longdouble` or `clongdouble`, `item()` returns a scalar array object because there is no available Python scalar that would not lose information. Void arrays return a buffer object for `item()`, unless fields are defined, in which case a tuple is returned.

item is very similar to `a[args]`, except, instead of an array scalar, a standard Python scalar is returned. This can be useful for speeding up access to elements of the array and doing arithmetic on elements of the array using Python's optimized math.

Examples

```
>>> import numpy as np
>>> np.random.seed(123)
>>> x = np.random.randint(9, size=(3, 3))
>>> x
array([[2, 2, 6],
       [1, 3, 6],
       [1, 0, 1]])
>>> x.item(3)
1
>>> x.item(7)
0
>>> x.item((0, 1))
2
>>> x.item((2, 2))
1
```

For an array with object dtype, elements are returned as-is.

```
>>> a = np.array([np.int64(1)], dtype=np.object_)
>>> a.item() #return np.int64
np.int64(1)
```

method

`char.chararray.join(seq)`

Return a string which is the concatenation of the strings in the sequence *seq*.

See also:

char.join

method

`char.chararray.ljust(width, fillchar='')`

Return an array with the elements of *self* left-justified in a string of length *width*.

See also:

char.ljust

method

`char.chararray.lower()`

Return an array with the elements of *self* converted to lowercase.

See also:

[`char.lower`](#)

method

`char.chararray.lstrip(chars=None)`

For each element in *self*, return a copy with the leading characters removed.

See also:

[`char.lstrip`](#)

method

`char.chararray.nonzero()`

Return the indices of the elements that are non-zero.

Refer to [`numpy.nonzero`](#) for full documentation.

See also:

[`numpy.nonzero`](#)
equivalent function

method

`char.chararray.put(indices, values, mode='raise')`

Set `a.flat[n] = values[n]` for all `n` in indices.

Refer to [`numpy.put`](#) for full documentation.

See also:

[`numpy.put`](#)
equivalent function

method

`char.chararray.ravel(order='C')`

Return a flattened array.

Refer to [`numpy.ravel`](#) for full documentation.

See also:

[`numpy.ravel`](#)
equivalent function

[`ndarray.flat`](#)
a flat iterator on the array.

method

`char.chararray.repeat` (*repeats*, *axis=None*)

Repeat elements of an array.

Refer to [`numpy.repeat`](#) for full documentation.

See also:

[`numpy.repeat`](#)
equivalent function

method

`char.chararray.replace` (*old*, *new*, *count=None*)

For each element in *self*, return a copy of the string with all occurrences of substring *old* replaced by *new*.

See also:

[`char.replace`](#)

method

`char.chararray.reshape` (*shape*, */*, ***, *order='C'*, *copy=None*) *a.reshape*(**shape*, *order='C'*, *copy=None*)

`char.chararray.reshape` (**shape*, *order='C'*, *copy=None*) → `None`

Returns an array containing the same data with a new shape.

Refer to [`numpy.reshape`](#) for full documentation.

See also:

[`numpy.reshape`](#)
equivalent function

Notes

Unlike the free function [`numpy.reshape`](#), this method on `ndarray` allows the elements of the shape parameter to be passed in as separate arguments. For example, `a.reshape(4, 2)` is equivalent to `a.reshape((4, 2))`.

method

`char.chararray.resize` (*new_shape*, */*, ***, *refcheck=True*) *a.resize*(**new_shape*, *refcheck=True*)

`char.chararray.resize` (**new_shape*, *refcheck=True*) → `None`

Change shape and size of array in-place.

Parameters

new_shape

[tuple of ints, or *n* ints] Shape of resized array.

refcheck

[bool, optional] If False, reference count will not be checked. Default is True. See Notes below for more explanation.

Returns

`None`

Raises

ValueError

If *a* does not own its own data or references or views to may exist.

See also:***resize***

Return a new array with the specified shape.

Notes

This reallocates space for the data area if necessary.

Only contiguous arrays (data elements consecutive in memory) can be resized.

Reallocating arrays in-place can often lead to memory fragmentation and should be avoided. If the goal is to reclaim over-allocated memory, alternatives are to create a view or a copy of just the desired data, or using two passes to build the array: one to cheaply determine the shape and another to allocate and fill. Benchmark your use case to determine what is optimum. You may be surprised to find `resize` actually slows down or bloats your application.

The purpose of the reference count check is to make sure you do not use this array as a buffer for another Python object and then reallocate the memory.

On Python 3.13 and older, the check allows objects with exactly one reference to be reallocated in-place. On Python 3.14 and newer, the array must be uniquely referenced. See [1] for more details.

If you are sure that you have not shared the memory for this array with another Python object, then you may safely set `refcheck` to `False`.

References

[1]

Examples

Shrinking an array: array is flattened (in the order that the data are stored in memory), resized, and reshaped:

```
>>> import numpy as np
```

```
>>> a = np.array([[0, 1], [2, 3]], order='C')
>>> a.resize((2, 1))
>>> a
array([[0],
       [1]])
```

```
>>> a = np.array([[0, 1], [2, 3]], order='F')
>>> a.resize((2, 1))
>>> a
array([[0],
       [2]])
```

Enlarging an array: as above, but missing entries are filled with zeros:

```
>>> b = np.array([[0, 1], [2, 3]])
>>> b.resize(2, 3) # new_shape parameter doesn't have to be a tuple
>>> b
array([[0, 1, 2],
       [3, 0, 0]])
```

Referencing an array prevents resizing...

```
>>> c = a
>>> a.resize((1, 1))
Traceback (most recent call last):
...
ValueError: cannot resize an array that references or is referenced ...
```

Unless *refcheck* is False:

```
>>> a.resize((1, 1), refcheck=False)
>>> a
array([[0]])
>>> c
array([[0]])
```

method

`char.chararray.rfind(sub, start=0, end=None)`

For each element in *self*, return the highest index in the string where substring *sub* is found, such that *sub* is contained within [*start*, *end*].

See also:

[*char.rfind*](#)

method

`char.chararray.rindex(sub, start=0, end=None)`

Like *rfind*, but raises `ValueError` when the substring *sub* is not found.

See also:

[*char.rindex*](#)

method

`char.chararray.rjust(width, fillchar='')`

Return an array with the elements of *self* right-justified in a string of length *width*.

See also:

[*char.rjust*](#)

method

`char.chararray.rsplit(sep=None, maxsplit=None)`

For each element in *self*, return a list of the words in the string, using *sep* as the delimiter string.

See also:

[*char.rsplit*](#)

method

`char.chararray.rstrip (chars=None)`

For each element in *self*, return a copy with the trailing characters removed.

See also:

[*char.rstrip*](#)

method

`char.chararray.searchsorted (v, side='left', sorter=None)`

Find indices where elements of *v* should be inserted in *a* to maintain order.

For full documentation, see [*numpy.searchsorted*](#).

See also:

[*numpy.searchsorted*](#)
equivalent function

method

`char.chararray.setfield (val, dtype, offset=0)`

Put a value into a specified place in a field defined by a data-type.

Place *val* into *a*'s field defined by *dtype* and beginning *offset* bytes into the field.

Parameters

val

[object] Value to be placed in field.

dtype

[dtype object] Data-type of the field in which to place *val*.

offset

[int, optional] The number of bytes into the field at which to place *val*.

Returns

None

See also:

[*getfield*](#)

Examples

```
>>> import numpy as np
>>> x = np.eye(3)
>>> x.getfield(np.float64)
array([[1.,  0.,  0.],
       [0.,  1.,  0.],
       [0.,  0.,  1.]])
>>> x.setfield(3, np.int32)
>>> x.getfield(np.int32)
array([[3, 3, 3],
       [3, 3, 3],
       [3, 3, 3]])
```

(continues on next page)

(continued from previous page)

```

[3, 3, 3]], dtype=int32)
>>> x
array([[1.0e+000, 1.5e-323, 1.5e-323],
       [1.5e-323, 1.0e+000, 1.5e-323],
       [1.5e-323, 1.5e-323, 1.0e+000]])
>>> x.setfield(np.eye(3), np.int32)
>>> x
array([[1., 0., 0.],
       [0., 1., 0.],
       [0., 0., 1.]])

```

method

`char.chararray.setflags` (*write=None, align=None, uic=None*)

Set array flags WRITEABLE, ALIGNED, WRITEBACKIFCOPY, respectively.

These Boolean-valued flags affect how numpy interprets the memory area used by *a* (see Notes below). The ALIGNED flag can only be set to True if the data is actually aligned according to the type. The WRITEBACKIFCOPY flag can never be set to True. The flag WRITEABLE can only be set to True if the array owns its own memory, or the ultimate owner of the memory exposes a writeable buffer interface, or is a string. (The exception for string is made so that unpickling can be done without copying memory.)

Parameters

write

[bool, optional] Describes whether or not *a* can be written to.

align

[bool, optional] Describes whether or not *a* is aligned properly for its type.

uic

[bool, optional] Describes whether or not *a* is a copy of another “base” array.

Notes

Array flags provide information about how the memory area used for the array is to be interpreted. There are 7 Boolean flags in use, only three of which can be changed by the user: WRITEBACKIFCOPY, WRITEABLE, and ALIGNED.

WRITEABLE (W) the data area can be written to;

ALIGNED (A) the data and strides are aligned appropriately for the hardware (as determined by the compiler);

WRITEBACKIFCOPY (X) this array is a copy of some other array (referenced by `.base`). When the C-API function `PyArray_ResolveWritebackIfCopy` is called, the base array will be updated with the contents of this array.

All flags can be accessed using the single (upper case) letter as well as the full name.

Examples

```
>>> import numpy as np
>>> y = np.array([[3, 1, 7],
...               [2, 0, 0],
...               [8, 5, 9]])
>>> y
array([[3, 1, 7],
       [2, 0, 0],
       [8, 5, 9]])
>>> y.flags
C_CONTIGUOUS : True
F_CONTIGUOUS : False
OWNDATA : True
WRITEABLE : True
ALIGNED : True
WRITEBACKIFCOPY : False
>>> y.setflags(write=0, align=0)
>>> y.flags
C_CONTIGUOUS : True
F_CONTIGUOUS : False
OWNDATA : True
WRITEABLE : False
ALIGNED : False
WRITEBACKIFCOPY : False
>>> y.setflags(uic=1)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: cannot set WRITEBACKIFCOPY flag to True
```

method

`char.chararray.sort` (*axis=-1, kind=None, order=None, *, stable=None, descending=None*)

Sort an array in-place. Refer to [numpy.sort](#) for full documentation.

Parameters

axis

[int, optional] Axis along which to sort. Default is -1, which means sort along the last axis.

kind

[[‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’], optional] Sorting algorithm. The default is ‘quicksort’. Note that both ‘stable’ and ‘mergesort’ use timsort under the covers and, in general, the actual implementation will vary with datatype. The ‘mergesort’ option is retained for backwards compatibility.

order

[str or list of str, optional] When *a* is an array with fields defined, this argument specifies which fields to compare first, second, etc. A single field can be specified as a string, and not all fields need be specified, but unspecified fields will still be used, in the order in which they come up in the dtype, to break ties.

stable

[bool, optional] Sort stability. If True, the returned array will maintain the relative order of a values which compare as equal. If False or None, this is not guaranteed. Internally, this option selects `kind='stable'`. Default: None.

New in version 2.0.0.

See also:

`numpy.sort`

Return a sorted copy of an array.

`numpy.argsort`

Indirect sort.

`numpy.lexsort`

Indirect stable sort on multiple keys.

`numpy.searchsorted`

Find elements in sorted array.

`numpy.partition`

Partial sort.

Notes

See `numpy.sort` for notes on the different sorting algorithms.

Examples

```
>>> import numpy as np
>>> a = np.array([[1,4], [3,1]])
>>> a.sort(axis=1)
>>> a
array([[1, 4],
       [1, 3]])
>>> a.sort(axis=0)
>>> a
array([[1, 3],
       [1, 4]])
```

Use the `order` keyword to specify a field to use when sorting a structured array:

```
>>> a = np.array([('a', 2), ('c', 1)], dtype=[('x', 'S1'), ('y', int)])
>>> a.sort(order='y')
>>> a
array([(b'c', 1), (b'a', 2)],
      dtype=[('x', 'S1'), ('y', '<i8')])
```

method

`char.chararray.split` (*sep=None, maxsplit=None*)

For each element in *self*, return a list of the words in the string, using *sep* as the delimiter string.

See also:

`char.split`

method

`char.chararray.splitlines` (*keepends=None*)

For each element in *self*, return a list of the lines in the element, breaking at line boundaries.

See also:

`char.splitlines`

method

`char.chararray.squeeze` (*axis=None*)

Remove axes of length one from *a*.

Refer to `numpy.squeeze` for full documentation.

See also:

`numpy.squeeze`

equivalent function

method

`char.chararray.startswith` (*prefix, start=0, end=None*)

Returns a boolean array which is *True* where the string element in *self* starts with *prefix*, otherwise *False*.

See also:

`char.startswith`

method

`char.chararray.strip` (*chars=None*)

For each element in *self*, return a copy with the leading and trailing characters removed.

See also:

`char.strip`

method

`char.chararray.swapaxes` (*axis1, axis2, /*)

Return a view of the array with *axis1* and *axis2* interchanged.

Refer to `numpy.swapaxes` for full documentation.

See also:

`numpy.swapaxes`

equivalent function

method

`char.chararray.swapcase` ()

For each element in *self*, return a copy of the string with uppercase characters converted to lowercase and vice versa.

See also:

`char.swapcase`

method

`char.chararray.take` (*indices, axis=None, out=None, mode='raise'*)

Return an array formed from the elements of *a* at the given indices.

Refer to `numpy.take` for full documentation.

See also:

numpy.take

equivalent function

method

`char.chararray.title()`

For each element in *self*, return a titlecased version of the string: words start with uppercase characters, all remaining cased characters are lowercase.

See also:

char.title

method

`char.chararray.tofile(fid, /, sep=",", format='%s')`

Write array to a file as text or binary (default).

Data is always written in ‘C’ order, independent of the order of *a*. The data produced by this method can be recovered using the function `fromfile()`.

Parameters

fid

[file or str or Path] An open file object, or a string containing a filename.

sep

[str] Separator between array items for text output. If “” (empty), a binary file is written, equivalent to `file.write(a.tobytes())`.

format

[str] Format string for text file output. Each entry in the array is formatted to text by first converting it to the closest Python type, and then using “format” % item.

Notes

This is a convenience function for quick storage of array data. Information on endianness and precision is lost, so this method is not a good choice for files intended to archive data or transport data between machines with different endianness. Some of these problems can be overcome by outputting the data as text files, at the expense of speed and file size.

When *fid* is a file object, array contents are directly written to the file, bypassing the file object’s `write` method. As a result, `tofile` cannot be used with files objects supporting compression (e.g., `GzipFile`) or file-like objects that do not support `fileno()` (e.g., `BytesIO`).

method

`char.chararray.tolist()`

Return the array as an *a.ndim*-levels deep nested list of Python scalars.

Return a copy of the array data as a (nested) Python list. Data items are converted to the nearest compatible builtin Python type, via the *item* method.

If *a.ndim* is 0, then since the depth of the nested list is 0, it will not be a list at all, but a simple Python scalar.

Parameters

none

Returns

y
[object, or list of object, or list of list of object, or ...] The possibly nested list of array elements.

Notes

The array may be recreated via `a = np.array(a.tolist())`, although this may sometimes lose precision.

Examples

For a 1D array, `a.tolist()` is almost the same as `list(a)`, except that `tolist` changes numpy scalars to Python scalars:

```
>>> import numpy as np
>>> a = np.uint32([1, 2])
>>> a_list = list(a)
>>> a_list
[np.uint32(1), np.uint32(2)]
>>> type(a_list[0])
<class 'numpy.uint32'>
>>> a_tolist = a.tolist()
>>> a_tolist
[1, 2]
>>> type(a_tolist[0])
<class 'int'>
```

Additionally, for a 2D array, `tolist` applies recursively:

```
>>> a = np.array([[1, 2], [3, 4]])
>>> list(a)
[array([1, 2]), array([3, 4])]
>>> a.tolist()
[[1, 2], [3, 4]]
```

The base case for this recursion is a 0D array:

```
>>> a = np.array(1)
>>> list(a)
Traceback (most recent call last):
...
TypeError: iteration over a 0-d array
>>> a.tolist()
1
```

method

`char.chararray.translate` (*table*, *deletechars=None*)

For each element in *self*, return a copy of the string where all characters occurring in the optional argument *deletechars* are removed, and the remaining characters have been mapped through the given translation table.

See also:

[`char.translate`](#)

method

`char.chararray.transpose(*axes)`

Returns a view of the array with axes transposed.

Refer to `numpy.transpose` for full documentation.

Parameters

axes

[None, tuple of ints, or *n* ints]

- None or no argument: reverses the order of the axes.
- tuple of ints: *i* in the *j*-th place in the tuple means that the array's *i*-th axis becomes the transposed array's *j*-th axis.
- *n* ints: same as an *n*-tuple of the same ints (this form is intended simply as a “convenience” alternative to the tuple form).

Returns

p

[ndarray] View of the array with its axes suitably permuted.

See also:

`transpose`

Equivalent function.

`ndarray.T`

Array property returning the array transposed.

`ndarray.reshape`

Return a reshaped ndarray without changing data.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> a
array([[1, 2],
       [3, 4]])
>>> a.transpose()
array([[1, 3],
       [2, 4]])
>>> a.transpose((1, 0))
array([[1, 3],
       [2, 4]])
>>> a.transpose(1, 0)
array([[1, 3],
       [2, 4]])
```

```
>>> a = np.array([1, 2, 3, 4])
>>> a
array([1, 2, 3, 4])
>>> a.transpose()
array([1, 2, 3, 4])
```

method

```
char.chararray.upper()
```

Return an array with the elements of *self* converted to uppercase.

See also:

char.upper

method

```
char.chararray.view([dtype][, type])
```

New view of array with the same data.

Note: Passing `None` for `dtype` is different from omitting the parameter, since the former invokes `dtype(None)` which is an alias for `dtype(np.float64)`.

Parameters

dtype

[data-type or ndarray sub-class, optional] Data-type descriptor of the returned view, e.g., `float32` or `int16`. Omitting it results in the view having the same data-type as *a*. This argument can also be specified as an ndarray sub-class, which then specifies the type of the returned object (this is equivalent to setting the `type` parameter).

type

[Python type, optional] Type of the returned view, e.g., `ndarray` or `matrix`. Again, omission of the parameter results in type preservation.

Notes

`a.view()` is used two different ways:

`a.view(some_dtype)` or `a.view(dtype=some_dtype)` constructs a view of the array's memory with a different data-type. This can cause a reinterpretation of the bytes of memory.

`a.view(ndarray_subclass)` or `a.view(type=ndarray_subclass)` just returns an instance of *ndarray_subclass* that looks at the same array (same shape, dtype, etc.) This does not cause a reinterpretation of the memory.

For `a.view(some_dtype)`, if `some_dtype` has a different number of bytes per entry than the previous dtype (for example, converting a regular array to a structured array), then the last axis of *a* must be contiguous. This axis will be resized in the result.

Changed in version 1.23.0: Only the last axis needs to be contiguous. Previously, the entire array had to be C-contiguous.

Examples

```
>>> import numpy as np
>>> x = np.array([(-1, 2)], dtype=[('a', np.int8), ('b', np.int8)])
```

Viewing array data using a different type and dtype:

```
>>> nonneg = np.dtype [("a", np.uint8), ("b", np.uint8)]
>>> y = x.view(dtype=nonneg, type=np.recarray)
>>> x["a"]
array([-1], dtype=int8)
>>> y.a
array([255], dtype=uint8)
```

Creating a view on a structured array so it can be used in calculations

```
>>> x = np.array([(1, 2), (3, 4)], dtype=[('a', np.int8), ('b', np.int8)])
>>> xv = x.view(dtype=np.int8).reshape(-1, 2)
>>> xv
array([[1, 2],
       [3, 4]], dtype=int8)
>>> xv.mean(0)
array([2., 3.])
```

Making changes to the view changes the underlying array

```
>>> xv[0, 1] = 20
>>> x
array([(1, 20), (3, 4)], dtype=[('a', 'i1'), ('b', 'i1')])
```

Using a view to convert an array to a recarray:

```
>>> z = x.view(np.recarray)
>>> z.a
array([1, 3], dtype=int8)
```

Views share data:

```
>>> x[0] = (9, 10)
>>> z[0]
np.record((9, 10), dtype=[('a', 'i1'), ('b', 'i1')])
```

Views that change the dtype size (bytes per entry) should normally be avoided on arrays defined by slices, transposes, fortran-ordering, etc.:

```
>>> x = np.array([[1, 2, 3], [4, 5, 6]], dtype=np.int16)
>>> y = x[:, ::2]
>>> y
array([[1, 3],
       [4, 6]], dtype=int16)
>>> y.view(dtype=[('width', np.int16), ('length', np.int16)])
Traceback (most recent call last):
...
ValueError: To change to a dtype of a different size, the last axis must be
↳contiguous
>>> z = y.copy()
>>> z.view(dtype=[('width', np.int16), ('length', np.int16)])
```

(continues on next page)

(continued from previous page)

```
array([[ (1, 3)],
       [(4, 6)]], dtype=[('width', '<i2'), ('length', '<i2')])
```

However, views that change dtype are totally fine for arrays with a contiguous last axis, even if the rest of the axes are not C-contiguous:

```
>>> x = np.arange(2 * 3 * 4, dtype=np.int8).reshape(2, 3, 4)
>>> x.transpose(1, 0, 2).view(np.int16)
array([[[ 256,  770],
        [3340, 3854]],

       [[1284, 1798],
        [4368, 4882]],

       [[2312, 2826],
        [5396, 5910]]], dtype=int16)
```

method

`char.chararray.zfill(width)`

Return the numeric string left-filled with zeros in a string of length *width*.

See also:

[`char.zfill`](#)

Examples

```
>>> import numpy as np
>>> charar = np.char.chararray((3, 3))
>>> charar[:] = 'a'
>>> charar
chararray([[b'a', b'a', b'a'],
          [b'a', b'a', b'a'],
          [b'a', b'a', b'a']], dtype='|S1')
```

```
>>> charar = np.char.chararray(charar.shape, itemsize=5)
>>> charar[:] = 'abc'
>>> charar
chararray([[b'abc', b'abc', b'abc'],
          [b'abc', b'abc', b'abc'],
          [b'abc', b'abc', b'abc']], dtype='|S5')
```

F2PY user guide and reference manual

The purpose of the F2PY –*Fortran to Python interface generator*– utility is to provide a connection between Python and Fortran. F2PY distributed as part of NumPy (`numpy.f2py`) and once installed is also available as a standalone command line tool. Originally created by Pearu Peterson, and older changelogs are in the [historical reference](#).

F2PY facilitates creating/building native [Python C/API extension modules](#) that make it possible

- to call Fortran 77/90/95 external subroutines and Fortran 90/95 module subroutines as well as C functions;
- to access Fortran 77 COMMON blocks and Fortran 90/95 module data, including allocatable arrays

from Python.

Note: Fortran 77 is essentially feature complete, and an increasing amount of Modern Fortran is supported within F2PY. Most `iso_c_binding` interfaces can be compiled to native extension modules automatically with `f2py`. Bug reports welcome!

F2PY can be used either as a command line tool `f2py` or as a Python module `numpy.f2py`. While we try to provide the command line tool as part of the numpy setup, some platforms like Windows make it difficult to reliably put the executables on the `PATH`. If the `f2py` command is not available in your system, you may have to run it as a module:

```
python -m numpy.f2py
```

Using the `python -m` invocation is also good practice if you have multiple Python installs with NumPy in your system (outside of virtual environments) and you want to ensure you pick up a particular version of Python/F2PY.

If you run `f2py` with no arguments, and the line `numpy Version` at the end matches the NumPy version printed from `python -m numpy.f2py`, then you can use the shorter version. If not, or if you cannot run `f2py`, you should replace all calls to `f2py` mentioned in this guide with the longer version.

For Meson build examples, see [Using F2PY](#).

F2PY user guide

Three ways to wrap - getting started

Wrapping Fortran or C functions to Python using F2PY consists of the following steps:

- Creating the so-called *signature file* that contains descriptions of wrappers to Fortran or C functions, also called the signatures of the functions. For Fortran routines, F2PY can create an initial signature file by scanning Fortran source codes and tracking all relevant information needed to create wrapper functions.
 - Optionally, F2PY-created signature files can be edited to optimize wrapper functions, which can make them “smarter” and more “Pythonic”.
- F2PY reads a signature file and writes a Python C/API module containing Fortran/C/Python bindings.
- F2PY compiles all sources and builds an extension module containing the wrappers.
 - In building the extension modules, F2PY uses `meson`. For different build systems, see [F2PY and build systems](#).

Note:

- Depending on your operating system, you may need to install the Python development headers (which provide the file `Python.h`) separately. In Linux Debian-based distributions this package should be called `python3-dev`, in Fedora-based distributions it is `python3-devel`. For macOS, depending how Python was installed, your mileage may vary. In Windows, the headers are typically installed already, see [F2PY and Windows](#).
-

Note: F2PY supports all the operating systems SciPy is tested on so their [system dependencies panel](#) is a good reference.

Depending on the situation, these steps can be carried out in a single composite command or step-by-step; in which case some steps can be omitted or combined with others.

Below, we describe three typical approaches of using F2PY with Fortran 77. These can be read in order of increasing effort, but also cater to different access levels depending on whether the Fortran code can be freely modified.

The following example Fortran 77 code will be used for illustration, save it as `fib1.f`:

```
C FILE: FIB1.F
  SUBROUTINE FIB(A,N)
C
C   CALCULATE FIRST N FIBONACCI NUMBERS
C
  INTEGER N
  REAL*8 A(N)
  DO I=1,N
    IF (I.EQ.1) THEN
      A(I) = 0.0D0
    ELSEIF (I.EQ.2) THEN
      A(I) = 1.0D0
    ELSE
      A(I) = A(I-1) + A(I-2)
    ENDIF
  ENDDO
  END
C END FILE FIB1.F
```

Note: F2PY parses Fortran/C signatures to build wrapper functions to be used with Python. However, it is not a compiler, and does not check for additional errors in source code, nor does it implement the entire language standards. Some errors may pass silently (or as warnings) and need to be verified by the user.

The quick way

The quickest way to wrap the Fortran subroutine `FIB` for use in Python is to run

```
python -m numpy.f2py -c fib1.f -m fib1
```

or, alternatively, if the `f2py` command-line tool is available,

```
f2py -c fib1.f -m fib1
```

Note: Because the `f2py` command might not be available in all system, notably on Windows, we will use the `python -m numpy.f2py` command throughout this guide.

This command compiles and wraps `fib1.f` (`-c`) to create the extension module `fib1.so` (`-m`) in the current directory. A list of command line options can be seen by executing `python -m numpy.f2py`. Now, in Python the Fortran subroutine `FIB` is accessible via `fib1.fib`:

```
>>> import numpy as np
>>> import fib1
>>> print(fib1.fib.__doc__)
fib(a, [n])

Wrapper for ``fib``.

Parameters
-----
a : input rank-1 array('d') with bounds (n)
```

(continues on next page)

(continued from previous page)

```

Other parameters
-----
n : input int, optional
    Default: len(a)

>>> a = np.zeros(8, 'd')
>>> fib1.fib(a)
>>> print(a)
[ 0.  1.  1.  2.  3.  5.  8. 13.]

```

Note:

- Note that F2PY recognized that the second argument `n` is the dimension of the first array argument `a`. Since by default all arguments are input-only arguments, F2PY concludes that `n` can be optional with the default value `len(a)`.
- One can use different values for optional `n`:

```

>>> a1 = np.zeros(8, 'd')
>>> fib1.fib(a1, 6)
>>> print(a1)
[ 0.  1.  1.  2.  3.  5.  0.  0.]

```

but an exception is raised when it is incompatible with the input array `a`:

```

>>> fib1.fib(a, 10)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
fib.error: (len(a)>=n) failed for 1st keyword n: fib:n=10
>>>

```

F2PY implements basic compatibility checks between related arguments in order to avoid unexpected crashes.

- When a NumPy array that is Fortran contiguous and has a `dtype` corresponding to a presumed Fortran type is used as an input array argument, then its C pointer is directly passed to Fortran.

Otherwise, F2PY makes a contiguous copy (with the proper `dtype`) of the input array and passes a C pointer of the copy to the Fortran subroutine. As a result, any possible changes to the (copy of) input array have no effect on the original argument, as demonstrated below:

```

>>> a = np.ones(8, 'i')
>>> fib1.fib(a)
>>> print(a)
[1 1 1 1 1 1 1 1]

```

Clearly, this is unexpected, as Fortran typically passes by reference. That the above example worked with `dtype=float` is considered accidental.

F2PY provides an `intent(inplace)` attribute that ensures that changes are copied back to the input argument. For example, if one specifies the `intent(inplace)` a directive (see [Attributes](#) for details), then the example above would read:

```

>>> a = np.ones(8, 'i')
>>> fib1.fib(a)
>>> print(a)
[ 0.  1.  1.  2.  3.  5.  8. 13.]

```

However, the recommended way to have changes made by Fortran subroutine propagate to Python is to use the `intent(out)` attribute. That approach is more efficient and also cleaner.

- The usage of `fib1.fib` in Python is very similar to using `FIB` in Fortran. However, using *in situ* output arguments in Python is poor style, as there are no safety mechanisms in Python to protect against wrong argument types. When using Fortran or C, compilers discover any type mismatches during the compilation process, but in Python the types must be checked at runtime. Consequently, using *in situ* output arguments in Python may lead to difficult to find bugs, not to mention the fact that the codes will be less readable when all required type checks are implemented.

Though the approach to wrapping Fortran routines for Python discussed so far is very straightforward, it has several drawbacks (see the comments above). The drawbacks are due to the fact that there is no way for F2PY to determine the actual intention of the arguments; that is, there is ambiguity in distinguishing between input and output arguments. Consequently, F2PY assumes that all arguments are input arguments by default.

There are ways (see below) to remove this ambiguity by “teaching” F2PY about the true intentions of function arguments, and F2PY is then able to generate more explicit, easier to use, and less error prone wrappers for Fortran functions.

The smart way

If we want to have more control over how F2PY will treat the interface to our Fortran code, we can apply the wrapping steps one by one.

- First, we create a signature file from `fib1.f` by running:

```
python -m numpy.f2py fib1.f -m fib2 -h fib1.pyf
```

The signature file is saved to `fib1.pyf` (see the `-h` flag) and its contents are shown below.

```
!      -*- f90 -*-
python module fib2 ! in
  interface ! in :fib2
    subroutine fib(a,n) ! in :fib2:fib1.f
      real*8 dimension(n) :: a
      integer optional,check(len(a)>=n),depend(a) :: n=len(a)
    end subroutine fib
  end interface
end python module fib2

! This file was auto-generated with f2py (version:2.28.198-1366).
! See http://cens.ioc.ee/projects/f2py2e/
```

- Next, we’ll teach F2PY that the argument `n` is an input argument (using the `intent(in)` attribute) and that the result, i.e., the contents of `a` after calling the Fortran function `FIB`, should be returned to Python (using the `intent(out)` attribute). In addition, an array `a` should be created dynamically using the size determined by the input argument `n` (using the `depend(n)` attribute to indicate this dependence relation).

The contents of a suitably modified version of `fib1.pyf` (saved as `fib2.pyf`) are as follows:

```
!      -*- f90 -*-
python module fib2
  interface
    subroutine fib(a,n)
      real*8 dimension(n),intent(out),depend(n) :: a
      integer intent(in) :: n
    end subroutine fib
```

(continues on next page)

(continued from previous page)

```
end interface
end python module fib2
```

- Finally, we build the extension module by running:

```
python -m numpy.f2py -c fib2.pyf fib1.f
```

In Python:

```
>>> import fib2
>>> print(fib2.fib.__doc__)
a = fib(n)

Wrapper for ``fib``.

Parameters
-----
n : input int

Returns
-----
a : rank-1 array('d') with bounds (n)

>>> print(fib2.fib(8))
[ 0.  1.  1.  2.  3.  5.  8. 13.]
```

Note:

- The signature of `fib2.fib` now more closely corresponds to the intention of the Fortran subroutine `FIB`: given the number `n`, `fib2.fib` returns the first `n` Fibonacci numbers as a NumPy array. The new Python signature `fib2.fib` also rules out the unexpected behaviour in `fib1.fib`.
- Note that by default, using a single `intent(out)` also implies `intent(hide)`. Arguments that have the `intent(hide)` attribute specified will not be listed in the argument list of a wrapper function.

For more details, see *Signature file*.

The quick and smart way

The “smart way” of wrapping Fortran functions, as explained above, is suitable for wrapping (e.g. third party) Fortran codes for which modifications to their source codes are not desirable nor even possible.

However, if editing Fortran codes is acceptable, then the generation of an intermediate signature file can be skipped in most cases. F2PY specific attributes can be inserted directly into Fortran source codes using F2PY directives. A F2PY directive consists of special comment lines (starting with `Cf2py` or `!f2py`, for example) which are ignored by Fortran compilers but interpreted by F2PY as normal lines.

Consider a modified version of the previous Fortran code with F2PY directives, saved as `fib3.f`:

```
C FILE: FIB3.F
C      SUBROUTINE FIB(A,N)
C
C      CALCULATE FIRST N FIBONACCI NUMBERS
C
```

(continues on next page)

(continued from previous page)

```

      INTEGER N
      REAL*8 A(N)
Cf2py intent(in) n
Cf2py intent(out) a
Cf2py depend(n) a
      DO I=1,N
        IF (I.EQ.1) THEN
          A(I) = 0.0D0
        ELSEIF (I.EQ.2) THEN
          A(I) = 1.0D0
        ELSE
          A(I) = A(I-1) + A(I-2)
        ENDIF
      ENDDO
      END
C END FILE FIB3.F

```

Building the extension module can be now carried out in one command:

```
python -m numpy.f2py -c -m fib3 fib3.f
```

Notice that the resulting wrapper to FIB is as “smart” (unambiguous) as in the previous case:

```

>>> import fib3
>>> print(fib3.fib.__doc__)
a = fib(n)

Wrapper for ``fib``.

Parameters
-----
n : input int

Returns
-----
a : rank-1 array('d') with bounds (n)

>>> print(fib3.fib(8))
[ 0.  1.  1.  2.  3.  5.  8. 13.]

```

Using F2PY

This page contains a reference to all command-line options for the `f2py` command, as well as a reference to internal functions of the `numpy.f2py` module.

Using f2py as a command-line tool

When used as a command-line tool, f2py has three major modes, distinguished by the usage of `-c` and `-h` switches.

1. Signature file generation

To scan Fortran sources and generate a signature file, use

```
f2py -h <filename.pyf> <options> <fortran files> \
[[ only: <fortran functions> : ]                \
 [ skip: <fortran functions> : ]]...             \
[<fortran files> ...]
```

Note: A Fortran source file can contain many routines, and it is often not necessary to allow all routines to be usable from Python. In such cases, either specify which routines should be wrapped (in the `only: .. :` part) or which routines F2PY should ignore (in the `skip: .. :` part).

F2PY has no concept of a “per-file” `skip` or `only` list, so if functions are listed in `only`, no other functions will be taken from any other files.

If `<filename.pyf>` is specified as `stdout`, then signatures are written to standard output instead of a file.

Among other options (see below), the following can be used in this mode:

--overwrite-signature
Overwrites an existing signature file.

2. Extension module construction

To construct an extension module, use

```
f2py -m <modulename> <options> <fortran files> \
[[ only: <fortran functions> : ]                \
 [ skip: <fortran functions> : ]]...             \
[<fortran files> ...]
```

The constructed extension module is saved as `<modulename>module.c` to the current directory.

Here `<fortran files>` may also contain signature files. Among other options (see below), the following options can be used in this mode:

--debug-capi
Adds debugging hooks to the extension module. When using this extension module, various diagnostic information about the wrapper is written to the standard output, for example, the values of variables, the steps taken, etc.

-include '<includefile>'
Add a CPP `#include` statement to the extension module source. `<includefile>` should be given in one of the following forms

```
"filename.ext"
<filename.ext>
```

The include statement is inserted just before the wrapper functions. This feature enables using arbitrary C functions (defined in `<includefile>`) in F2PY generated wrappers.

Note: This option is deprecated. Use `usercode` statement to specify C code snippets directly in signature files.

--[no-]wrap-functions

Create Fortran subroutine wrappers to Fortran functions. `--wrap-functions` is default because it ensures maximum portability and compiler independence.

--[no-]freethreading-compatible

Create a module that declares it does or doesn't require the GIL. The default is `--no-freethreading-compatible` for backwards compatibility. Inspect the fortran code you are wrapping for thread safety issues before passing `--freethreading-compatible`, as `f2py` does not analyze fortran code for thread safety issues.

--include-paths "<path1>:<path2>..."

Search include files from given directories.

Note: The paths are to be separated by the correct operating system separator `pathsep`, that is `:` on Linux / MacOS and `;` on Windows. In CMake this corresponds to using `$<SEMICOLON>`.

3. Building a module

To build an extension module, use

```
f2py -c <options> <fortran files> \
  [[ only: <fortran functions> : ] \
  [ skip: <fortran functions> : ]]... \
  [ <fortran/c source files> ] [ <.o, .a, .so files> ]
```

If `<fortran files>` contains a signature file, then the source for an extension module is constructed, all Fortran and C sources are compiled, and finally all object and library files are linked to the extension module `<modulename>.so` which is saved into the current directory.

If `<fortran files>` does not contain a signature file, then an extension module is constructed by scanning all Fortran source codes for routine signatures, before proceeding to build the extension module.

Warning: `distutils` has been removed. Use environment variables or native files to interact with `meson` instead. See its [FAQ](#) for more information.

Among other options (see below) and options described for previous modes, the following can be used.

Note: Changed in version 2.5.0: The `distutils` backend has been removed.

Common build flags:

--backend <backend_type>

Legacy option, only `meson` is supported.

--f77flags=<string>

Specify F77 compiler flags

--f90flags=<string>

Specify F90 compiler flags

--debug

Compile with debugging information

-l<libname>

Use the library <libname> when linking.

-D<macro> [=<defn=1>]

Define macro <macro> as <defn>.

-U<macro>

Define macro <macro>

-I<dir>

Append directory <dir> to the list of directories searched for include files.

-L<dir>

Add directory <dir> to the list of directories to be searched for -l.

--dep <dependency>

Specify a meson dependency for the module. This may be passed multiple times for multiple dependencies. Dependencies are stored in a list for further processing. Example: `--dep lapack --dep scalapack` This will identify “lapack” and “scalapack” as dependencies and remove them from argv, leaving a dependencies list containing [“lapack”, “scalapack”].

Note: The `f2py -c` option must be applied either to an existing `.pyf` file (plus the source/object/library files) or one must specify the `-m <module name>` option (plus the sources/object/library files). Use one of the following options:

```
f2py -c -m fib1 fib1.f
```

or

```
f2py -m fib1 fib1.f -h fib1.pyf
f2py -c fib1.pyf fib1.f
```

For more information, see the [Building C and C++ Extensions](#) Python documentation for details.

When building an extension module, a combination of the following macros may be required for non-gcc Fortran compilers:

```
-DPREPEND_FORTRAN
-DNO_APPEND_FORTRAN
-DUPPERCASE_FORTRAN
```

To test the performance of F2PY generated interfaces, use `-DF2PY_REPORT_ATEXIT`. Then a report of various timings is printed out at the exit of Python. This feature may not work on all platforms, and currently only Linux is supported.

To see whether F2PY generated interface performs copies of array arguments, use `-DF2PY_REPORT_ON_ARRAY_COPY=<int>`. When the size of an array argument is larger than <int>, a message about the copying is sent to `stderr`.

Other options

-m <modulename>

Name of an extension module. Default is `untitled`.

Warning: Don't use this option if a signature file (`*.pyf`) is used.

Changed in version 1.26.3: Will ignore `-m` if a `pyf` file is provided.

--[no-]lower

Do [not] lower the cases in `<fortran files>`. By default, `--lower` is assumed with `-h` switch, and `--no-lower` without the `-h` switch.

-include<header>

Writes additional headers in the C wrapper, can be passed multiple times, generates `#include <header>` each time. Note that this is meant to be passed in single quotes and without spaces, for example `'-include<stdbool.h>'`

--build-dir <dirname>

All F2PY generated files are created in `<dirname>`. Default is `tempfile.mkdtemp()`.

--f2cmap <filename>

Load Fortran-to-C `KIND` specifications from the given file.

--quiet

Run quietly.

--verbose

Run with extra verbosity.

--skip-empty-wrappers

Do not generate wrapper files unless required by the inputs. This is a backwards compatibility flag to restore pre 1.22.4 behavior.

-v

Print the F2PY version and exit.

Execute `f2py` without any options to get an up-to-date list of available options.

Python module `numpy.f2py`

Warning: Changed in version 2.0.0: There used to be a `f2py.compile` function, which was removed, users may wrap `python -m numpy.f2py` via `subprocess.run` manually, and set environment variables to interact with `meson` as required.

When using `numpy.f2py` as a module, the following functions can be invoked. Fortran to Python Interface Generator.

Copyright 1999 – 2011 Pearu Peterson all rights reserved. Copyright 2011 – present NumPy Developers. Permission to use, modify, and distribute this software is given under the terms of the NumPy License.

NO WARRANTY IS EXPRESSED OR IMPLIED. USE AT YOUR OWN RISK.

`numpy.f2py.get_include()`

Return the directory that contains the `fortranobject.c` and `.h` files.

Python extension modules built with f2py-generated code need to use `fortranobject.c` as a source file, and include the `fortranobject.h` header. This function can be used to obtain the directory containing both of these files.

Returns

`include_path`

[str] Absolute path to the directory containing `fortranobject.c` and `fortranobject.h`.

See also:

`numpy.get_include`

function that returns the numpy include directory

Notes

New in version 1.21.1.

Unless the build system you are using has specific support for f2py, building a Python extension using a `.pyf` signature file is a two-step process. For a module `mymod`:

- Step 1: run `python -m numpy.f2py mymod.pyf --quiet`. This generates `mymodmodule.c` and (if needed) `mymod-f2pywrappers.f` files next to `mymod.pyf`.
- Step 2: build your Python extension module. This requires the following source files:
 - `mymodmodule.c`
 - `mymod-f2pywrappers.f` (if it was generated in Step 1)
 - `fortranobject.c`

`numpy.f2py.run_main` (*comline_list*)

Equivalent to running:

```
f2py <args>
```

where `<args>=string.join(<list>, ' ')`, but in Python. Unless `-h` is used, this function returns a dictionary containing information on generated modules and their dependencies on source files.

You cannot build extension modules with this function, that is, using `-c` is not allowed. Use the `compile` command instead.

Examples

The command `f2py -m scalar scalar.f` can be executed from Python as follows.

```
>>> import numpy.f2py
>>> r = numpy.f2py.run_main(['-m', 'scalar', 'doc/source/f2py/scalar.f'])
Reading fortran codes...
    Reading file 'doc/source/f2py/scalar.f' (format:fix,strict)
Post-processing...
    Block: scalar
                Block: FOO
Building modules...
    Building module "scalar"...
    Wrote C/API module "scalar" to file "./scalarmodule.c"
```

(continues on next page)

(continued from previous page)

```
>>> print(r)
{'scalar': {'h': ['/home/users/pearu/src_cvs/f2py/src/fortranobject.h'],
             'csrc': ['./scalarmodule.c',
                      '/home/users/pearu/src_cvs/f2py/src/fortranobject.c']}}
```

Building with Meson (Examples)

Using f2py with Meson

Meson is a modern build system recommended for building Python extension modules, especially starting with Python 3.12 and NumPy 2.x. Meson provides a robust and maintainable way to build Fortran extensions with f2py.

To build a Fortran extension using f2py and Meson, you can use Meson's `custom_target` to invoke f2py and generate the extension module. The following minimal example demonstrates how to do this:

This example shows how to build the `add` extension from the `add.f` and `add.pyf` files described in the *F2PY examples* (note that you do not always need a `.pyf` file: in many cases f2py can figure out the annotations by itself).

Project layout:

```
f2py_examples/
meson.build
add.f
add.pyf (optional)
__init__.py (can be empty)
```

Example `meson.build`:

```
project('f2py_examples', 'fortran')

py = import('python').find_installation()

# List your Fortran source files
sources = files('add.pyf', 'add.f')

# Build the extension by invoking f2py via a custom target
add_mod = custom_target(
    'add_extension',
    input: sources,
    output: ['add' + py.extension_suffix()],
    command: [
        py.full_path(), '-m', 'numpy.f2py',
        '-c', 'add.pyf', 'add.f',
        '-m', 'add'
    ],
    build_by_default: true
)

# Install into site-packages under the f2py_examples package
install_subdir('.', install_dir: join_paths(py.site_packages_dir(), 'f2py_examples'),
        strip_directory: false,
        exclude_files: ['meson.build'])

# Also install the built extension (place it beside __init__.py)
```

(continues on next page)

(continued from previous page)

```
install_data(add_mod, install_dir: join_paths(py.site_packages_dir(), 'f2py_examples
↪'))
```

For more details and advanced usage, see the Meson build guide in the user documentation or refer to SciPy's Meson build files for real-world examples: <https://github.com/scipy/scipy/tree/main/meson.build>

F2PY examples

Below are some examples of F2PY usage. This list is not comprehensive, but can be used as a starting point when wrapping your own code.

Note: The best place to look for examples is the [NumPy issue tracker](#), or the test cases for `f2py`. Some more use cases are in *Boilerplate reduction and templating*.

F2PY walkthrough: a basic extension module

Creating source for a basic extension module

Consider the following subroutine, contained in a file named `add.f`

```
C
SUBROUTINE ZADD (A, B, C, N)
C
DOUBLE COMPLEX A (*)
DOUBLE COMPLEX B (*)
DOUBLE COMPLEX C (*)
INTEGER N
DO 20 J = 1, N
    C (J) = A (J) + B (J)
20 CONTINUE
END
```

This routine simply adds the elements in two contiguous arrays and places the result in a third. The memory for all three arrays must be provided by the calling routine. A very basic interface to this routine can be automatically generated by `f2py`:

```
python -m numpy.f2py -m add add.f
```

This command will produce an extension module named `addmodule.c` in the current directory. This extension module can now be compiled and used from Python just like any other extension module.

Creating a compiled extension module

You can also get `f2py` to both compile `add.f` along with the produced extension module leaving only a shared-library extension file that can be imported from Python:

```
python -m numpy.f2py -c -m add add.f
```

This command produces a Python extension module compatible with your platform. This module may then be imported from Python. It will contain a method for each subroutine in `add`. The docstring of each method contains information about how the module method may be called:

```
>>> import add
>>> print(add.zadd.__doc__)
zadd(a,b,c,n)

Wrapper for ``zadd``.

Parameters
-----
a : input rank-1 array('D') with bounds (*)
b : input rank-1 array('D') with bounds (*)
c : input rank-1 array('D') with bounds (*)
n : input int
```

Improving the basic interface

The default interface is a very literal translation of the Fortran code into Python. The Fortran array arguments are converted to NumPy arrays and the integer argument should be mapped to a C integer. The interface will attempt to convert all arguments to their required types (and shapes) and issue an error if unsuccessful. However, because `f2py` knows nothing about the semantics of the arguments (such that `C` is an output and `n` should really match the array sizes), it is possible to abuse this function in ways that can cause Python to crash. For example:

```
>>> add.zadd([1, 2, 3], [1, 2], [3, 4], 1000)
```

will cause a program crash on most systems. Under the hood, the lists are being converted to arrays but then the underlying `add` function is told to cycle way beyond the borders of the allocated memory.

In order to improve the interface, `f2py` supports directives. This is accomplished by constructing a signature file. It is usually best to start from the interfaces that `f2py` produces in that file, which correspond to the default behavior. To get `f2py` to generate the interface file use the `-h` option:

```
python -m numpy.f2py -h add.pyf -m add add.f
```

This command creates the `add.pyf` file in the current directory. The section of this file corresponding to `zadd` is:

```
subroutine zadd(a,b,c,n) ! in :add:add.f
  double complex dimension(*) :: a
  double complex dimension(*) :: b
  double complex dimension(*) :: c
  integer :: n
end subroutine zadd
```

By placing intent directives and checking code, the interface can be cleaned up quite a bit so the Python module method is both easier to use and more robust to malformed inputs.

```
subroutine zadd(a,b,c,n) ! in :add:add.f
  double complex dimension(n) :: a
  double complex dimension(n) :: b
  double complex intent(out),dimension(n) :: c
  integer intent(hide),depend(a) :: n=len(a)
end subroutine zadd
```

The intent directive, intent(out) is used to tell f2py that `c` is an output variable and should be created by the interface before being passed to the underlying code. The intent(hide) directive tells f2py to not allow the user to specify the variable, `n`, but instead to get it from the size of `a`. The depend(`a`) directive is necessary to tell f2py that the value of `n` depends on the input `a` (so that it won't try to create the variable `n` until the variable `a` is created).

After modifying `add.pyf`, the new Python module file can be generated by compiling both `add.f` and `add.pyf`:

```
python -m numpy.f2py -c add.pyf add.f
```

The new interface's docstring is:

```
>>> import add
>>> print(add.zadd.__doc__)
c = zadd(a,b)

Wrapper for ``zadd``.

Parameters
-----
a : input rank-1 array('D') with bounds (n)
b : input rank-1 array('D') with bounds (n)

Returns
-----
c : rank-1 array('D') with bounds (n)
```

Now, the function can be called in a much more robust way:

```
>>> add.zadd([1, 2, 3], [4, 5, 6])
array([5.+0.j, 7.+0.j, 9.+0.j])
```

Notice the automatic conversion to the correct format that occurred.

Inserting directives in Fortran source

The robust interface of the previous section can also be generated automatically by placing the variable directives as special comments in the original Fortran code.

Note: For projects where the Fortran code is being actively developed, this may be preferred.

Thus, if the source code is modified to contain:

```
C
    SUBROUTINE ZADD (A,B,C,N)
C
CF2PY INTENT(OUT) :: C
CF2PY INTENT(HIDE) :: N
```

(continues on next page)

(continued from previous page)

```

CF2PY DOUBLE COMPLEX :: A(N)
CF2PY DOUBLE COMPLEX :: B(N)
CF2PY DOUBLE COMPLEX :: C(N)
      DOUBLE COMPLEX A(*)
      DOUBLE COMPLEX B(*)
      DOUBLE COMPLEX C(*)
      INTEGER N
      DO 20 J = 1, N
        C(J) = A(J) + B(J)
20    CONTINUE
      END

```

Then, one can compile the extension module using:

```
python -m numpy.f2py -c -m add add.f
```

The resulting signature for the function `add.zadd` is exactly the same one that was created previously. If the original source code had contained `A(N)` instead of `A(*)` and so forth with `B` and `C`, then nearly the same interface can be obtained by placing the `INTENT(OUT) :: C` comment line in the source code. The only difference is that `N` would be an optional input that would default to the length of `A`.

A filtering example

This example shows a function that filters a two-dimensional array of double precision floating-point numbers using a fixed averaging filter. The advantage of using Fortran to index into multi-dimensional arrays should be clear from this example.

```

C
      SUBROUTINE DFILTER2D(A,B,M,N)
C
      DOUBLE PRECISION A(M,N)
      DOUBLE PRECISION B(M,N)
      INTEGER N, M
CF2PY INTENT(OUT) :: B
CF2PY INTENT(HIDE) :: N
CF2PY INTENT(HIDE) :: M
      DO 20 I = 2,M-1
        DO 40 J = 2,N-1
          B(I,J) = A(I,J) +
&          (A(I-1,J)+A(I+1,J) +
&          A(I,J-1)+A(I,J+1) ) *0.5D0 +
&          (A(I-1,J-1) + A(I-1,J+1) +
&          A(I+1,J-1) + A(I+1,J+1) ) *0.25D0
40    CONTINUE
20    CONTINUE
      END

```

This code can be compiled and linked into an extension module named `filter` using:

```
python -m numpy.f2py -c -m filter filter.f
```

This will produce an extension module in the current directory with a method named `dfilter2d` that returns a filtered version of the input.

depends keyword example

Consider the following code, saved in the file `myroutine.f90`:

```
subroutine s(n, m, c, x)
  implicit none
  integer, intent(in) :: n, m
  real(kind=8), intent(out), dimension(n,m) :: x
  real(kind=8), intent(in) :: c(:)

  x = 0.0d0
  x(1, 1) = c(1)

end subroutine s
```

Wrapping this with `python -m numpy.f2py -c myroutine.f90 -m myroutine`, we can do the following in Python:

```
>>> import numpy as np
>>> import myroutine
>>> x = myroutine.s(2, 3, np.array([5, 6, 7]))
>>> x
array([[5., 0., 0.],
       [0., 0., 0.]])
```

Now, instead of generating the extension module directly, we will create a signature file for this subroutine first. This is a common pattern for multi-step extension module generation. In this case, after running

```
python -m numpy.f2py myroutine.f90 -m myroutine -h myroutine.pyf
```

the following signature file is generated:

```
!      -*- f90 -*-
! Note: the context of this file is case sensitive.

python module myroutine ! in
  interface ! in :myroutine
    subroutine s(n,m,c,x) ! in :myroutine:myroutine.f90
      integer intent(in) :: n
      integer intent(in) :: m
      real(kind=8) dimension(:), intent(in) :: c
      real(kind=8) dimension(n,m), intent(out), depend(m,n) :: x
    end subroutine s
  end interface
end python module myroutine

! This file was auto-generated with f2py (version:1.23.0.dev0+120.g4da01f42d).
! See:
! https://web.archive.org/web/20140822061353/http://cens.ioc.ee/projects/f2py2e
```

Now, if we run `python -m numpy.f2py -c myroutine.pyf myroutine.f90` we see an error; note that the signature file included a `depend(m,n)` statement for `x` which is not necessary. Indeed, editing the file above to read

```
!      -*- f90 -*-
! Note: the context of this file is case sensitive.
```

(continues on next page)

(continued from previous page)

```
python module myroutine ! in
  interface ! in :myroutine
    subroutine s(n,m,c,x) ! in :myroutine:myroutine.f90
      integer intent(in) :: n
      integer intent(in) :: m
      real(kind=8) dimension(:),intent(in) :: c
      real(kind=8) dimension(n,m),intent(out) :: x
    end subroutine s
  end interface
end python module myroutine

! This file was auto-generated with f2py (version:1.23.0.dev0+120.g4da01f42d).
! See:
! https://web.archive.org/web/20140822061353/http://cens.ioc.ee/projects/f2py2e
```

and running `f2py -c myroutine.pyf myroutine.f90` yields correct results.

F2PY reference manual

Signature file

The interface definition file (.pyf) is how you can fine-tune the interface between Python and Fortran. The syntax specification for signature files (.pyf files) is modeled on the Fortran 90/95 language specification. Almost all Fortran standard constructs are understood, both in free and fixed format (recall that Fortran 77 is a subset of Fortran 90/95). F2PY introduces some extensions to the Fortran 90/95 language specification that help in the design of the Fortran to Python interface, making it more “Pythonic”.

Signature files may contain arbitrary Fortran code so that any Fortran 90/95 codes can be treated as signature files. F2PY silently ignores Fortran constructs that are irrelevant for creating the interface. However, this also means that syntax errors are not caught by F2PY and will only be caught when the library is built.

Note: Currently, F2PY may fail with some valid Fortran constructs. If this happens, you can check the [NumPy GitHub issue tracker](#) for possible workarounds or work-in-progress ideas.

In general, the contents of the signature files are case-sensitive. When scanning Fortran codes to generate a signature file, F2PY lowers all cases automatically except in multi-line blocks or when the `--no-lower` option is used.

The syntax of signature files is presented below.

Signature files syntax

Python module block

A signature file may contain one (recommended) or more `python module` blocks. The `python module` block describes the contents of a Python/C extension module `<modulename>module.c` that F2PY generates.

Warning: Exception: if `<modulename>` contains a substring `__user__`, then the corresponding `python module` block describes the signatures of call-back functions (see [Call-back arguments](#)).

A `python module` block has the following structure:

```
python module <modulename>
  [<usercode statement>]...
  [
    interface
      <usercode statement>
      <Fortran block data signatures>
      <Fortran/C routine signatures>
    end [interface]
  ]...
  [
    interface
      module <F90 modulename>
        [<F90 module data type declarations>]
        [<F90 module routine signatures>]
      end [module [<F90 modulename>]]
    end [interface]
  ]...
end [python module [<modulename>]]
```

Here brackets `[]` indicate an optional section, dots `...` indicate one or more of a previous section. So, `[]...` is to be read as zero or more of a previous section.

Fortran/C routine signatures

The signature of a Fortran routine has the following structure:

```
[<typespec>] function | subroutine <routine name> \
      [ ( [<arguments>] ) ] [ result ( <entityname> ) ]
  [<argument/variable type declarations>]
  [<argument/variable attribute statements>]
  [<use statements>]
  [<common block statements>]
  [<other statements>]
end [ function | subroutine [<routine name>] ]
```

From a Fortran routine signature F2PY generates a Python/C extension function that has the following signature:

```
def <routine name>(<required arguments>[,<optional arguments>]):
    ...
    return <return variables>
```

The signature of a Fortran block data has the following structure:

```

block data [ <block data name> ]
  [<variable type declarations>]
  [<variable attribute statements>]
  [<use statements>]
  [<common block statements>]
  [<include statements>]
end [ block data [<block data name>] ]

```

Type declarations

The definition of the <argument/variable type declaration> part is

```
<typespec> [ [<attrspec>] :: ] <entitydecl>
```

where

```

<typespec> := byte | character [<charselector>]
            | complex [<kindselector>] | real [<kindselector>]
            | double complex | double precision
            | integer [<kindselector>] | logical [<kindselector>]

<charselector> := * <charlen>
                | ( [len=] <len> [ , [kind=] <kind> ] )
                | ( kind= <kind> [ , len= <len> ] )
<kindselector> := * <intlen> | ( [kind=] <kind> )

<entitydecl> := <name> [ [ * <charlen> ] [ ( <arrayspec> ) ]
                      | [ ( <arrayspec> ) ] * <charlen> ]
                | [ / <init_expr> / | = <init_expr> ] \
                [ , <entitydecl> ]

```

and

- <attrspec> is a comma separated list of *attributes*;
- <arrayspec> is a comma separated list of dimension bounds;
- <init_expr> is a *C expression*;
- <intlen> may be negative integer for integer type specifications. In such cases integer*<negintlen> represents unsigned C integers;

If an argument has no <argument type declaration>, its type is determined by applying implicit rules to its name.

Statements

Attribute statements

The <argument/variable attribute statement> is similar to the <argument/variable type declaration>, but without <typespec>.

An attribute statement cannot contain other attributes, and <entitydecl> can be only a list of names. See *Attributes* for more details on the attributes that can be used by F2PY.

Use statements

- The definition of the `<use statement>` part is

```
use <modulename> [ , <rename_list> | , ONLY : <only_list> ]
```

where

```
<rename_list> := <local_name> => <use_name> [ , <rename_list> ]
```

- Currently F2PY uses use statements only for linking call-back modules and external arguments (call-back functions). See [Call-back arguments](#).

Common block statements

- The definition of the `<common block statement>` part is

```
common / <common name> / <shortentitydecl>
```

where

```
<shortentitydecl> := <name> [ ( <arrayspec> ) ] [ , <shortentitydecl> ]
```

- If a `python` module block contains two or more `common` blocks with the same name, the variables from the additional declarations are appended. The types of variables in `<shortentitydecl>` are defined using `<argument type declarations>`. Note that the corresponding `<argument type declarations>` may contain array specifications; then these need not be specified in `<shortentitydecl>`.

Other statements

- The `<other statement>` part refers to any other Fortran language constructs that are not described above. F2PY ignores most of them except the following:

- call statements and function calls of external arguments (see [more details on external arguments](#));
- **include statements**

```
include '<filename>'  
include "<filename>"
```

If a file `<filename>` does not exist, the `include` statement is ignored. Otherwise, the file `<filename>` is included to a signature file. `include` statements can be used in any part of a signature file, also outside the Fortran/C routine signature blocks.

- **implicit statements**

```
implicit none  
implicit <list of implicit maps>
```

where

```
<implicit map> := <typespec> ( <list of letters or range of letters> )
```

Implicit rules are used to determine the type specification of a variable (from the first-letter of its name) if the variable is not defined using `<variable type declaration>`. Default implicit rules are given by:

```
implicit real (a-h,o-z,$_), integer (i-m)
```

- entry statements

```
entry <entry name> [[<arguments>]]
```

F2PY generates wrappers for all entry names using the signature of the routine block.

Note: The `entry` statement can be used to describe the signature of an arbitrary subroutine or function allowing F2PY to generate a number of wrappers from only one routine block signature. There are few restrictions while doing this: `fortranname` cannot be used, `callstatement` and `callprotoargument` can be used only if they are valid for all entry routines, etc.

F2PY statements

In addition, F2PY introduces the following statements:

threadsafe

Uses a `Py_BEGIN_ALLOW_THREADS .. Py_END_ALLOW_THREADS` block around the call to Fortran/C function.

callstatement <C-expr|multi-line block>

Replaces the F2PY generated call statement to Fortran/C function with `<C-expr|multi-line block>`. The wrapped Fortran/C function is available as `(*f2py_func)`.

To raise an exception, set `f2py_success = 0` in `<C-expr|multi-line block>`.

callprotoargument <C-typespecs>

When the `callstatement` statement is used, F2PY may not generate proper prototypes for Fortran/C functions (because `<C-expr>` may contain function calls, and F2PY has no way to determine what should be the proper prototype).

With this statement you can explicitly specify the arguments of the corresponding prototype:

```
extern <return type> FUNC_F(<routine name>,<ROUTINE NAME>)(<callprotoargument>);
```

fortranname [<actual Fortran/C routine name>]

F2PY allows for the use of an arbitrary `<routine name>` for a given Fortran/C function. Then this statement is used for the `<actual Fortran/C routine name>`.

If `fortranname` statement is used without `<actual Fortran/C routine name>` then a dummy wrapper is generated.

usercode <multi-line block>

When this is used inside a `python module block`, the given C code will be inserted to generated C/API source just before wrapper function definitions.

Here you can define arbitrary C functions to be used for the initialization of optional arguments.

For example, if `usercode` is used twice inside `python module block` then the second multi-line block is inserted after the definition of the external routines.

When used inside `<routine signature>`, then the given C code will be inserted into the corresponding wrapper function just after the declaration of variables but before any C statements. So, the `usercode` follow-up can contain both declarations and C statements.

When used inside the first `interface` block, then the given C code will be inserted at the end of the initialization function of the extension module. This is how the extension modules dictionary can be modified and has many use-cases; for example, to define additional variables.

pymethoddef <multiline block>

This is a multi-line block which will be inserted into the definition of a module methods `PyMethodDef`-array. It must be a comma-separated list of C arrays (see [Extending and Embedding Python](#) documentation for details). `pymethoddef` statement can be used only inside `python module` block.

Attributes

The following attributes can be used by F2PY.

optional

The corresponding argument is moved to the end of `<optional arguments>` list. A default value for an optional argument can be specified via `<init_expr>` (see the [entitydecl definition](#))

Note:

- The default value must be given as a valid C expression.
 - Whenever `<init_expr>` is used, the `optional` attribute is set automatically by F2PY.
 - For an optional array argument, all its dimensions must be bounded.
-

required

The corresponding argument with this attribute is considered mandatory. This is the default. `required` should only be specified if there is a need to disable the automatic `optional` setting when `<init_expr>` is used.

If a Python `None` object is used as a required argument, the argument is treated as optional. That is, in the case of array arguments, the memory is allocated. If `<init_expr>` is given, then the corresponding initialization is carried out.

dimension (<arrayspec>)

The corresponding variable is considered as an array with dimensions given in `<arrayspec>`.

intent (<intentspec>)

This specifies the “intention” of the corresponding argument. `<intentspec>` is a comma separated list of the following keys:

- **in**
The corresponding argument is considered to be input-only. This means that the value of the argument is passed to a Fortran/C function and that the function is expected to not change the value of this argument.
- **inout**
The corresponding argument is marked for input/output or as an *in situ* output argument. `intent(inout)` arguments can be only contiguous NumPy arrays (in either the Fortran or C sense) with proper type and size. The latter coincides with the default contiguous concept used in NumPy and is effective only if `intent(c)` is used. F2PY assumes Fortran contiguous arguments by default.

Note: Using `intent(inout)` is generally not recommended, as it can cause unexpected results. For example, scalar arguments using `intent(inout)` are assumed to be array objects in order to have *in situ* changes be effective. Use `intent(in,out)` instead.

See also the `intent(inplace)` attribute.

- **inplace**

The corresponding argument is considered to be an input/output or *in situ* output argument. `intent(inplace)` arguments must be NumPy arrays of a proper size. If the size of an array is not “proper” or the array is non-contiguous then the routine will be passed a fixed copy of array, which has the `NPY_ARRAY_WRITEBACKIFCOPY` flag set, so that the result will be copied back to the original array on exit.

Note: Since copies may be made, `intent(inplace)` can be slower than expected. It is recommended over `inout`, but not over `in`, `out`.

- **out**

The corresponding argument is considered to be a return variable. It is appended to the `<returned variables>` list. Using `intent(out)` sets `intent(hide)` automatically, unless `intent(in)` or `intent(inout)` are specified as well.

By default, returned multidimensional arrays are Fortran-contiguous. If `intent(c)` attribute is used, then the returned multidimensional arrays are C-contiguous.

- **hide**

The corresponding argument is removed from the list of required or optional arguments. Typically `intent(hide)` is used with `intent(out)` or when `<init_expr>` completely determines the value of the argument like in the following example:

```
integer intent(hide),depend(a) :: n = len(a)
real intent(in),dimension(n) :: a
```

- **c**

The corresponding argument is treated as a C scalar or C array argument. For the case of a scalar argument, its value is passed to a C function as a C scalar argument (recall that Fortran scalar arguments are actually C pointer arguments). For array arguments, the wrapper function is assumed to treat multidimensional arrays as C-contiguous arrays.

There is no need to use `intent(c)` for one-dimensional arrays, irrespective of whether the wrapped function is in Fortran or C. This is because the concepts of Fortran- and C contiguity overlap in one-dimensional cases.

If `intent(c)` is used as a statement but without an entity declaration list, then F2PY adds the `intent(c)` attribute to all arguments.

Also, when wrapping C functions, one must use `intent(c)` attribute for `<routine name>` in order to disable Fortran specific `F_FUNC(...)` macros.

- **cache**

The corresponding argument is treated as junk memory. No Fortran nor C contiguity checks are carried out. Using `intent(cache)` makes sense only for array arguments, also in conjunction with `intent(hide)` or optional attributes.

- **copy**

Ensures that the original contents of `intent(in)` argument is preserved. Typically used with the `intent(in,out)` attribute. F2PY creates an optional argument `overwrite_<argument name>` with the default value 0.

- **overwrite**

This indicates that the original contents of the `intent(in)` argument may be altered by the Fortran/C function. F2PY creates an optional argument `overwrite_<argument name>` with the default value 1.

- **out=<new name>**

Replaces the returned name with <new name> in the `__doc__` string of the wrapper function.

- **callback**

Constructs an external function suitable for calling Python functions from Fortran. `intent(callback)` must be specified before the corresponding external statement. If the 'argument' is not in the argument list then it will be added to Python wrapper but only by initializing an external function.

Note: Use `intent(callback)` in situations where the Fortran/C code assumes that the user implemented a function with a given prototype and linked it to an executable. Don't use `intent(callback)` if the function appears in the argument list of a Fortran routine.

With `intent(hide)` or optional attributes specified and using a wrapper function without specifying the callback argument in the argument list; then the call-back function is assumed to be found in the namespace of the F2PY generated extension module where it can be set as a module attribute by a user.

- **aux**

Defines an auxiliary C variable in the F2PY generated wrapper function. Useful to save parameter values so that they can be accessed in initialization expressions for other variables.

Note: `intent(aux)` silently implies `intent(c)`.

The following rules apply:

- If none of `intent(in | inout | out | hide)` are specified, `intent(in)` is assumed.
 - `intent(in, inout)` is `intent(in)`;
 - `intent(in, hide)` or `intent(inout, hide)` is `intent(hide)`;
 - `intent(out)` is `intent(out, hide)` unless `intent(in)` or `intent(inout)` is specified.
- If `intent(copy)` or `intent(overwrite)` is used, then an additional optional argument is introduced with a name `overwrite_<argument name>` and a default value 0 or 1, respectively.
 - `intent(inout, inplace)` is `intent(inplace)`;
 - `intent(in, inplace)` is `intent(inplace)`;
 - `intent(hide)` disables optional and required.

check([<C-booleanexpr>])

Performs a consistency check on the arguments by evaluating <C-booleanexpr>; if <C-booleanexpr> returns 0, an exception is raised.

Note: If `check(. .)` is not used then F2PY automatically generates a few standard checks (e.g. in a case of an array argument, it checks for the proper shape and size). Use `check()` to disable checks generated by F2PY.

depend([<names>])

This declares that the corresponding argument depends on the values of variables in the <names> list. For example, <init_expr> may use the values of other arguments. Using information given by `depend(. .)` attributes, F2PY ensures that arguments are initialized in a proper order. If the `depend(. .)` attribute is not used then F2PY determines dependence relations automatically. Use `depend()` to disable the dependence relations generated by F2PY.

When you edit dependence relations that were initially generated by F2PY, be careful not to break the dependence relations of other relevant variables. Another thing to watch out for is cyclic dependencies. F2PY is able to detect cyclic dependencies when constructing wrappers and it complains if any are found.

allocatable

The corresponding variable is a Fortran 90 allocatable array defined as Fortran 90 module data.

external

The corresponding argument is a function provided by user. The signature of this call-back function can be defined

- in `__user__` module block,
- or by demonstrative (or real, if the signature file is a real Fortran code) call in the `<other statements>` block.

For example, F2PY generates from:

```
external cb_sub, cb_fun
integer n
real a(n), r
call cb_sub(a, n)
r = cb_fun(4)
```

the following call-back signatures:

```
subroutine cb_sub(a, n)
  real dimension(n) :: a
  integer optional, check(len(a) >= n), depend(a) :: n=len(a)
end subroutine cb_sub
function cb_fun(e_4_e) result(r)
  integer :: e_4_e
  real :: r
end function cb_fun
```

The corresponding user-provided Python function are then:

```
def cb_sub(a, [n]):
    ...
    return
def cb_fun(e_4_e):
    ...
    return r
```

See also the `intent(callback)` attribute.

parameter

This indicates that the corresponding variable is a parameter and it must have a fixed value. F2PY replaces all parameter occurrences by their corresponding values.

Extensions

F2PY directives

The F2PY directives allow using F2PY signature file constructs in Fortran 77/90 source codes. With this feature one can (almost) completely skip the intermediate signature file generation and apply F2PY directly to Fortran source codes.

F2PY directives have the following form:

```
<comment char>f2py ...
```

where allowed comment characters for fixed and free format Fortran codes are `cC*!#` and `!`, respectively. Everything that follows `<comment char>f2py` is ignored by a compiler but read by F2PY as a normal non-comment Fortran line:

Note: When F2PY finds a line with F2PY directive, the directive is first replaced by 5 spaces and then the line is reread.

For fixed format Fortran codes, `<comment char>` must be at the first column of a file, of course. For free format Fortran codes, the F2PY directives can appear anywhere in a file.

C expressions

C expressions are used in the following parts of signature files:

- `<init_expr>` for variable initialization;
- `<C-booleanexpr>` of the check attribute;
- `<arrayspec>` of the dimension attribute;
- `callstatement` statement, here also a C multi-line block can be used.

A C expression may contain:

- standard C constructs;
- functions from `math.h` and `Python.h`;
- variables from the argument list, presumably initialized before according to given dependence relations;
- the following CPP macros:

f2py_rank(<name>)

Returns the rank of an array `<name>`.

f2py_shape(<name>, <n>)

Returns the `<n>`-th dimension of an array `<name>`.

f2py_len(<name>)

Returns the length of an array `<name>`.

f2py_size(<name>)

Returns the size of an array `<name>`.

f2py_itemsize(<name>)

Returns the itemsize of an array `<name>`.

f2py_slen(<name>)

Returns the length of a string `<name>`.

For initializing an array `<array name>`, F2PY generates a loop over all indices and dimensions that executes the following pseudo-statement:

```
<array name>(_i[0],_i[1],...) = <init_expr>;
```

where `_i[<i>]` refers to the `<i>`-th index value and that runs from 0 to `shape(<array name>, <i>)-1`.

For example, a function `myrange(n)` generated from the following signature

```
subroutine myrange(a,n)
  fortranname      ! myrange is a dummy wrapper
  integer intent(in) :: n
  real*8 intent(c,out),dimension(n),depend(n) :: a = _i[0]
end subroutine myrange
```

is equivalent to `numpy.arange(n, dtype=float)`.

Warning: F2PY may lower cases also in C expressions when scanning Fortran codes (see `--[no]-lower` option).

Multi-line blocks

A multi-line block starts with `'''` (triple single-quotes) and ends with `'''` in some *strictly* subsequent line. Multi-line blocks can be used only within `.pyf` files. The contents of a multi-line block can be arbitrary (except that it cannot contain `'''`) and no transformations (e.g. lowering cases) are applied to it.

Currently, multi-line blocks can be used in the following constructs:

- as a C expression of the `callstatement` statement;
- as a C type specification of the `callprotoargument` statement;
- as a C code block of the `usercode` statement;
- as a list of C arrays of the `pymethoddef` statement;
- as documentation string.

Extended char-selector

F2PY extends char-selector specification, usable within a signature file or a F2PY directive, as follows:

```
<extended-charselector> := <charselector>
                          | (f2py_len= <len>)
```

See *Character strings* for usage.

Using F2PY bindings in Python

In this page, you can find a full description and a few examples of common usage patterns for F2PY with Python and different argument types. For more examples and use cases, see [F2PY examples](#).

Fortran type objects

All wrappers for Fortran/C routines, common blocks, or Fortran 90 module data generated by F2PY are exposed to Python as `fortran` type objects. Routine wrappers are callable `fortran` type objects while wrappers to Fortran data have attributes referring to data objects.

All `fortran` type objects have an attribute `_cpointer` that contains a `PyCapsule` referring to the C pointer of the corresponding Fortran/C function or variable at the C level. Such `PyCapsule` objects can be used as callback arguments for F2PY generated functions to bypass the Python C/API layer for calling Python functions from Fortran or C. This can be useful when the computational aspects of such functions are implemented in C or Fortran and wrapped with F2PY (or any other tool capable of providing the `PyCapsule` containing a function).

Consider a Fortran 77 file `ftype.f`:

```
C FILE: FTYPE.F
    SUBROUTINE FOO(N)
    INTEGER N
Cf2py integer optional,intent(in) :: n = 13
    REAL A,X
    COMMON /DATA/ A,X(3)
C    PRINT*, "IN FOO: N=",N, " A=",A, " X=[",X(1),X(2),X(3), "]"
    END
C END OF FTYPE.F
```

and a wrapper built using `f2py -c ftype.f -m ftype`.

In Python, you can observe the types of `foo` and `data`, and how to access individual objects of the wrapped Fortran code.

```
>>> import ftype
>>> print(ftype.__doc__)
This module 'ftype' is auto-generated with f2py (version:2).
Functions:
    foo(n=13)
COMMON blocks:
    /data/ a,x(3)
.
>>> type(ftype.foo), type(ftype.data)
(<class 'fortran'>, <class 'fortran'>)
>>> ftype.foo()
IN FOO: N= 13 A=  0. X=[  0.  0.  0.]
>>> ftype.data.a = 3
>>> ftype.data.x = [1,2,3]
>>> ftype.foo()
IN FOO: N= 13 A=  3. X=[  1.  2.  3.]
>>> ftype.data.x[1] = 45
>>> ftype.foo(24)
IN FOO: N= 24 A=  3. X=[  1. 45.  3.]
>>> ftype.data.x
array([ 1., 45.,  3.], dtype=float32)
```

Scalar arguments

In general, a scalar argument for a F2PY generated wrapper function can be an ordinary Python scalar (integer, float, complex number) as well as an arbitrary sequence object (list, tuple, array, string) of scalars. In the latter case, the first element of the sequence object is passed to the Fortran routine as a scalar argument.

Note:

- When type-casting is required and there is possible loss of information via narrowing e.g. when type-casting float to integer or complex to float, F2PY *does not* raise an exception.
 - For complex to real type-casting only the real part of a complex number is used.
- `intent(inout)` scalar arguments are assumed to be array objects in order to have *in situ* changes be effective. It is recommended to use arrays with proper type but also other types work. [Read more about the `intent` attribute.](#)

Consider the following Fortran 77 code:

```
C FILE: SCALAR.F
  SUBROUTINE FOO(A,B)
    REAL*8 A, B
Cf2py intent(in) a
Cf2py intent(inout) b
    PRINT*, "    A=",A, " B=",B
    PRINT*, "INCREMENT A AND B"
    A = A + 1D0
    B = B + 1D0
    PRINT*, "NEW A=",A, " B=",B
    END
C END OF FILE SCALAR.F
```

and wrap it using `f2py -c -m scalar scalar.f`.

In Python:

```
>>> import scalar
>>> print(scalar.foo.__doc__)
foo(a,b)

Wrapper for ``foo``.

Parameters
-----
a : input float
b : in/output rank-0 array(float,'d')

>>> scalar.foo(2, 3)
    A=  2. B=  3.
    INCREMENT A AND B
    NEW A=  3. B=  4.
>>> import numpy
>>> a = numpy.array(2)    # these are integer rank-0 arrays
>>> b = numpy.array(3)
>>> scalar.foo(a, b)
    A=  2. B=  3.
    INCREMENT A AND B
    NEW A=  3. B=  4.
```

(continues on next page)

(continued from previous page)

```
>>> print(a, b)           # note that only b is changed in situ
2 4
```

String arguments

F2PY generated wrapper functions accept almost any Python object as a string argument, since `str` is applied for non-string objects. Exceptions are NumPy arrays that must have type code `'S1'` or `'b'` (corresponding to the outdated `'c'` or `'1'` typecodes, respectively) when used as string arguments. See [Scalars](#) for more information on these typecodes.

A string can have an arbitrary length when used as a string argument for an F2PY generated wrapper function. If the length is greater than expected, the string is truncated silently. If the length is smaller than expected, additional memory is allocated and filled with `\0`.

Because Python strings are immutable, an `intent(inout)` argument expects an array version of a string in order to have *in situ* changes be effective.

Consider the following Fortran 77 code:

```
C FILE: STRING.F
  SUBROUTINE FOO(A,B,C,D)
    CHARACTER*5 A, B
    CHARACTER*(*) C,D
Cf2py intent(in) a,c
Cf2py intent(inout) b,d
    PRINT*, "A=",A
    PRINT*, "B=",B
    PRINT*, "C=",C
    PRINT*, "D=",D
    PRINT*, "CHANGE A,B,C,D"
    A(1:1) = 'A'
    B(1:1) = 'B'
    C(1:1) = 'C'
    D(1:1) = 'D'
    PRINT*, "A=",A
    PRINT*, "B=",B
    PRINT*, "C=",C
    PRINT*, "D=",D
    END
C END OF FILE STRING.F
```

and wrap it using `f2py -c -m mystring string.f`.

Python session:

```
>>> import mystring
>>> print(mystring.foo.__doc__)
foo(a,b,c,d)

Wrapper for ``foo``.

Parameters
-----
a : input string(len=5)
b : in/output rank-0 array(string(len=5),'c')
c : input string(len=-1)
d : in/output rank-0 array(string(len=-1),'c')
```

(continues on next page)

(continued from previous page)

```

>>> from numpy import array
>>> a = array(b'123\0\0')
>>> b = array(b'123\0\0')
>>> c = array(b'123')
>>> d = array(b'123')
>>> mystring.foo(a, b, c, d)
A=123
B=123
C=123
D=123
CHANGE A,B,C,D
A=A23
B=B23
C=C23
D=D23
>>> a[()], b[()], c[()], d[()]
(b'123', b'B23', b'123', b'D2')

```

Array arguments

In general, array arguments for F2PY generated wrapper functions accept arbitrary sequences that can be transformed to NumPy array objects. There are two notable exceptions:

- `intent(inout)` array arguments must always be proper-contiguous and have a compatible dtype, otherwise an exception is raised.
- `intent(inplace)` array arguments must be arrays. If these have incompatible order or size, a converted copy is passed in, which is copied back into the original array on exit (see the `intent(inplace)` [attribute](#) for more information).

In general, if a NumPy array is proper-contiguous and has a proper type then it is directly passed to the wrapped Fortran/C function. Otherwise, an element-wise copy of the input array is made and the copy, being proper-contiguous and with proper type, is used as the array argument.

Usually there is no need to worry about how the arrays are stored in memory and whether the wrapped functions, being either Fortran or C functions, assume one or another storage order. F2PY automatically ensures that wrapped functions get arguments with the proper storage order; the underlying algorithm is designed to make copies of arrays only when absolutely necessary. However, when dealing with very large multidimensional input arrays with sizes close to the size of the physical memory in your computer, then care must be taken to ensure the usage of proper-contiguous and proper type arguments.

To transform input arrays to column major storage order before passing them to Fortran routines, use the function `numpy.asfortranarray`.

Consider the following Fortran 77 code:

```

C FILE: ARRAY.F
      SUBROUTINE FOO(A,N,M)
C
C      INCREMENT THE FIRST ROW AND DECREMENT THE FIRST COLUMN OF A
C
      INTEGER N,M,I,J
      REAL*8 A(N,M)
Cf2py intent(in,out,copy) a
Cf2py integer intent(hide),depend(a) :: n=shape(a,0), m=shape(a,1)

```

(continues on next page)

(continued from previous page)

```

DO J=1,M
  A(1,J) = A(1,J) + 1D0
ENDDO
DO I=1,N
  A(I,1) = A(I,1) - 1D0
ENDDO
END
C END OF FILE ARRAY.F

```

and wrap it using `f2py -c -m arr array.f -DF2PY_REPORT_ON_ARRAY_COPY=1`.

In Python:

```

>>> import arr
>>> from numpy import asfortranarray
>>> print(arr.foo.__doc__)
a = foo(a,[overwrite_a])

Wrapper for ``foo``.

Parameters
-----
a : input rank-2 array('d') with bounds (n,m)

Other Parameters
-----
overwrite_a : input int, optional
    Default: 0

Returns
-----
a : rank-2 array('d') with bounds (n,m)

>>> a = arr.foo([[1, 2, 3],
...             [4, 5, 6]])
created an array from object
>>> print(a)
[[ 1.  3.  4.]
 [ 3.  5.  6.]]
>>> a.flags.c_contiguous
False
>>> a.flags.f_contiguous
True
# even if a is proper-contiguous and has proper type,
# a copy is made forced by intent(copy) attribute
# to preserve its original contents
>>> b = arr.foo(a)
copied an array: size=6, elsize=8
>>> print(a)
[[ 1.  3.  4.]
 [ 3.  5.  6.]]
>>> print(b)
[[ 1.  4.  5.]
 [ 2.  5.  6.]]
>>> b = arr.foo(a, overwrite_a = 1) # a is passed directly to Fortran
...                               # routine and its contents is discarded
...

```

(continues on next page)

(continued from previous page)

```

>>> print(a)
[[ 1.  4.  5.]
 [ 2.  5.  6.]]
>>> print(b)
[[ 1.  4.  5.]
 [ 2.  5.  6.]]
>>> a is b                                     # a and b are actually the same objects
True
>>> print(arr.foo([1, 2, 3]))                 # different rank arrays are allowed
created an array from object
[ 1.  1.  2.]
>>> print(arr.foo([[[1], [2], [3]]]))
created an array from object
[[[ 1.]
   [ 1.]
   [ 2.]]]
>>>
>>> # Creating arrays with column major data storage order:
...
>>> s = asfortranarray([[1, 2, 3], [4, 5, 6]])
>>> s.flags.f_contiguous
True
>>> print(s)
[[1 2 3]
 [4 5 6]]
>>> print(arr.foo(s))
>>> s2 = asfortranarray(s)
>>> s2 is s      # an array with column major storage order
                  # is returned immediately
True
>>> # Note that arr.foo returns a column major data storage order array:
...
>>> s3 = ascontiguousarray(s)
>>> s3.flags.f_contiguous
False
>>> s3.flags.c_contiguous
True
>>> s3 = arr.foo(s3)
copied an array: size=6, elsize=8
>>> s3.flags.f_contiguous
True
>>> s3.flags.c_contiguous
False

```

Call-back arguments

F2PY supports calling Python functions from Fortran or C codes.

Consider the following Fortran 77 code:

```

C FILE: CALLBACK.F
  SUBROUTINE FOO(FUN,R)
  EXTERNAL FUN
  INTEGER I
  REAL*8 R, FUN

```

(continues on next page)

(continued from previous page)

```

Cf2py intent(out) r
    R = 0D0
    DO I=-5,5
        R = R + FUN(I)
    ENDDO
    END
C END OF FILE CALLBACK.F

```

and wrap it using `f2py -c -m callback callback.f`.

In Python:

```

>>> import callback
>>> print(callback.foo.__doc__)
r = foo(fun,[fun_extra_args])

Wrapper for ``foo``.

Parameters
-----
fun : call-back function

Other Parameters
-----
fun_extra_args : input tuple, optional
    Default: ()

Returns
-----
r : float

Notes
-----
Call-back functions::

    def fun(i): return r
    Required arguments:
        i : input int
    Return objects:
        r : float

>>> def f(i): return i*i
...
>>> print(callback.foo(f))
110.0
>>> print(callback.foo(lambda i:1))
11.0

```

In the above example F2PY was able to guess accurately the signature of the call-back function. However, sometimes F2PY cannot establish the appropriate signature; in these cases the signature of the call-back function must be explicitly defined in the signature file.

To facilitate this, signature files may contain special modules (the names of these modules contain the special `__user__` sub-string) that define the various signatures for call-back functions. Callback arguments in routine signatures have the external attribute (see also the `intent(callback)` [attribute](#)). To relate a callback argument with its signature in a `__user__` module block, a `use` statement can be utilized as illustrated below. The same signature for a callback argument can be referred to in different routine signatures.

We use the same Fortran 77 code as in the previous example but now we will pretend that F2PY was not able to guess the signatures of call-back arguments correctly. First, we create an initial signature file `callback2.pyf` using F2PY:

```
f2py -m callback2 -h callback2.pyf callback.f
```

Then modify it as follows

```
!      -*- f90 -*-
python module __user__routines
  interface
    function fun(i) result (r)
      integer :: i
      real*8 :: r
    end function fun
  end interface
end python module __user__routines

python module callback2
  interface
    subroutine foo(f,r)
      use __user__routines, f=>fun
      external f
      real*8 intent(out) :: r
    end subroutine foo
  end interface
end python module callback2
```

Finally, we build the extension module using `f2py -c callback2.pyf callback.f`.

An example Python session for this snippet would be identical to the previous example except that the argument names would differ.

Sometimes a Fortran package may require that users provide routines that the package will use. F2PY can construct an interface to such routines so that Python functions can be called from Fortran.

Consider the following Fortran 77 subroutine that takes an array as its input and applies a function `func` to its elements.

```
      subroutine calculate(x,n)
cf2py intent(callback) func
      external func
c      The following lines define the signature of func for F2PY:
cf2py real*8 y
cf2py y = func(y)
c
cf2py intent(in,out,copy) x
      integer n,i
      real*8 x(n), func
      do i=1,n
        x(i) = func(x(i))
      end do
      end
```

The Fortran code expects that the function `func` has been defined externally. In order to use a Python function for `func`, it must have an attribute `intent(callback)` and it must be specified before the `external` statement.

Finally, build an extension module using `f2py -c -m foo calculate.f`

In Python:

```
>>> import foo
>>> foo.calculate(range(5), lambda x: x*x)
array([ 0.,  1.,  4.,  9., 16.])
>>> import math
>>> foo.calculate(range(5), math.exp)
array([ 1.          ,  2.71828183,  7.3890561, 20.08553692, 54.59815003])
```

The function is included as an argument to the python function call to the Fortran subroutine even though it was *not* in the Fortran subroutine argument list. The “external” keyword refers to the C function generated by f2py, not the Python function itself. The python function is essentially being supplied to the C function.

The callback function may also be explicitly set in the module. Then it is not necessary to pass the function in the argument list to the Fortran function. This may be desired if the Fortran function calling the Python callback function is itself called by another Fortran function.

Consider the following Fortran 77 subroutine:

```
subroutine f1()
  print *, "in f1, calling f2 twice.."
  call f2()
  call f2()
  return
end

subroutine f2()
cf2py  intent(callback, hide) fpy
       external fpy
  print *, "in f2, calling f2py.."
  call fpy()
  return
end
```

and wrap it using `f2py -c -m pfromf extcallback.f`.

In Python:

```
>>> import pfromf
>>> pfromf.f2()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
pfromf.error: Callback fpy not defined (as an argument or module pfromf attribute).

>>> def f(): print("python f")
...
>>> pfromf.fpy = f
>>> pfromf.f2()
in f2, calling f2py..
python f
>>> pfromf.f1()
in f1, calling f2 twice..
in f2, calling f2py..
python f
in f2, calling f2py..
python f
>>>
```

Note: When using modified Fortran code via `callstatement` or other directives, the wrapped Python function must be called as a callback, otherwise only the bare Fortran routine will be used. For more details, see <https://github.com/>

[numpy/numpy/issues/26681#issuecomment-2466460943](https://numpy.org/doc/stable/issues/26681#issuecomment-2466460943)

Resolving arguments to call-back functions

F2PY generated interfaces are very flexible with respect to call-back arguments. For each call-back argument an additional optional argument `<name>_extra_args` is introduced by F2PY. This argument can be used to pass extra arguments to user provided call-back functions.

If a F2PY generated wrapper function expects the following call-back argument:

```
def fun(a_1, ..., a_n):
    ...
    return x_1, ..., x_k
```

but the following Python function

```
def gun(b_1, ..., b_m):
    ...
    return y_1, ..., y_l
```

is provided by a user, and in addition,

```
fun_extra_args = (e_1, ..., e_p)
```

is used, then the following rules are applied when a Fortran or C function evaluates the call-back argument `gun`:

- If $p == 0$ then `gun(a_1, ..., a_q)` is called, here $q = \min(m, n)$.
- If $n + p \leq m$ then `gun(a_1, ..., a_n, e_1, ..., e_p)` is called.
- If $p \leq m < n + p$ then `gun(a_1, ..., a_q, e_1, ..., e_p)` is called, and here $q = m - p$.
- If $p > m$ then `gun(e_1, ..., e_m)` is called.
- If $n + p$ is less than the number of required arguments to `gun` then an exception is raised.

If the function `gun` may return any number of objects as a tuple; then the following rules are applied:

- If $k < l$, then `y_{k+1}, ..., y_l` are ignored.
- If $k > l$, then only `x_1, ..., x_l` are set.

Common blocks

F2PY generates wrappers to `common` blocks defined in a routine signature block. Common blocks are visible to all Fortran codes linked to the current extension module, but not to other extension modules (this restriction is due to the way Python imports shared libraries). In Python, the F2PY wrappers to `common` blocks are `fortran` type objects that have (dynamic) attributes related to the data members of the common blocks. When accessed, these attributes return as NumPy array objects (multidimensional arrays are Fortran-contiguous) which directly link to data members in common blocks. Data members can be changed by direct assignment or by in-place changes to the corresponding array objects.

Consider the following Fortran 77 code:

```
C FILE: COMMON.F
  SUBROUTINE FOO
    INTEGER I, X
    REAL A
```

(continues on next page)

(continued from previous page)

```

COMMON /DATA/ I,X(4),A(2,3)
PRINT*, "I=",I
PRINT*, "X=[",X,"]"
PRINT*, "A=[ "
PRINT*, "[",A(1,1)," ",A(1,2)," ",A(1,3)," ]"
PRINT*, "[",A(2,1)," ",A(2,2)," ",A(2,3)," ]"
PRINT*, "]"
END
C END OF COMMON.F

```

and wrap it using `f2py -c -m common common.f`.

In Python:

```

>>> import common
>>> print(common.data.__doc__)
i : 'i'-scalar
x : 'i'-array(4)
a : 'f'-array(2,3)

>>> common.data.i = 5
>>> common.data.x[1] = 2
>>> common.data.a = [[1,2,3],[4,5,6]]
>>> common.foo()
>>> common.foo()
I=          5
X=[          0          2          0          0 ]
A=[
[  1.00000000      ,  2.00000000      ,  3.00000000      ]
[  4.00000000      ,  5.00000000      ,  6.00000000      ]
]

>>> common.data.a[1] = 45
>>> common.foo()
I=          5
X=[          0          2          0          0 ]
A=[
[  1.00000000      ,  2.00000000      ,  3.00000000      ]
[ 45.00000000      , 45.00000000      , 45.00000000      ]
]

>>> common.data.a                                # a is Fortran-contiguous
array([[ 1.,  2.,  3.],
       [45., 45., 45.]], dtype=float32)
>>> common.data.a.flags.f_contiguous
True

```

Fortran 90 module data

The F2PY interface to Fortran 90 module data is similar to the handling of Fortran 77 common blocks.

Consider the following Fortran 90 code:

```

module mod
  integer i
  integer :: x(4)
  real, dimension(2,3) :: a

```

(continues on next page)

(continued from previous page)

```

    real, allocatable, dimension(:,:) :: b
contains
  subroutine foo
    integer k
    print*, "i=",i
    print*, "x=[" ,x," ]"
    print*, "a=["
    print*, "[",a(1,1)," ",a(1,2)," ",a(1,3)," ]"
    print*, "[",a(2,1)," ",a(2,2)," ",a(2,3)," ]"
    print*, "]"
    print*, "Setting a(1,2)=a(1,2)+3"
    a(1,2) = a(1,2)+3
  end subroutine foo
end module mod

```

and wrap it using `f2py -c -m moddata moddata.f90`.

In Python:

```

>>> import moddata
>>> print(moddata.mod.__doc__)
i : 'i'-scalar
x : 'i'-array(4)
a : 'f'-array(2,3)
b : 'f'-array(-1,-1), not allocated
foo()

Wrapper for ``foo``.

>>> moddata.mod.i = 5
>>> moddata.mod.x[:2] = [1,2]
>>> moddata.mod.a = [[1,2,3],[4,5,6]]
>>> moddata.mod.foo()
i=          5
x=[          1          2          0          0 ]
a=[
[  1.000000      ,  2.000000      ,  3.000000      ]
[  4.000000      ,  5.000000      ,  6.000000      ]
]
Setting a(1,2)=a(1,2)+3
>>> moddata.mod.a           # a is Fortran-contiguous
array([[ 1.,  5.,  3.],
       [ 4.,  5.,  6.]], dtype=float32)
>>> moddata.mod.a.flags.f_contiguous
True

```

Allocatable arrays

F2PY has basic support for Fortran 90 module allocatable arrays.

Consider the following Fortran 90 code:

```
module mod
  real, allocatable, dimension(:,:) :: b
contains
  subroutine foo
    integer k
    if (allocated(b)) then
      print*, "b=["
      do k = 1,size(b,1)
        print*, b(k,1:size(b,2))
      enddo
      print*, "]"
    else
      print*, "b is not allocated"
    endif
  end subroutine foo
end module mod
```

and wrap it using `f2py -c -m allocarr allocarr.f90`.

In Python:

```
>>> import allocarr
>>> print(allocarr.mod.__doc__)
b : 'f'-array(-1,-1), not allocated
foo()

Wrapper for ``foo``.

>>> allocarr.mod.foo()
b is not allocated
>>> allocarr.mod.b = [[1, 2, 3], [4, 5, 6]]           # allocate/initialize b
>>> allocarr.mod.foo()
b=[
  1.000000      2.000000      3.000000
  4.000000      5.000000      6.000000
]
>>> allocarr.mod.b                                     # b is Fortran-contiguous
array([[ 1.,  2.,  3.],
       [ 4.,  5.,  6.]], dtype=float32)
>>> allocarr.mod.b.flags.f_contiguous
True
>>> allocarr.mod.b = [[1, 2, 3], [4, 5, 6], [7, 8, 9]] # reallocate/initialize b
>>> allocarr.mod.foo()
b=[
  1.000000      2.000000      3.000000
  4.000000      5.000000      6.000000
  7.000000      8.000000      9.000000
]
>>> allocarr.mod.b = None                               # deallocate array
>>> allocarr.mod.foo()
b is not allocated
```

F2PY and build systems

In this section we will cover the various popular build systems and their usage with `f2py`.

Changed in version NumPy: 1.26.x

The default build system for `f2py` has traditionally been through the enhanced `numpy.distutils` module. This module is based on `distutils` which was removed in NumPy 2.5.0 in **June 2026**. Like the rest of NumPy and SciPy, `f2py` uses `meson` now, see [Status of numpy.distutils and migration advice](#) for some more details.

All changes to `f2py` are tested on SciPy, so their [CI configuration](#) is always supported.

Note: See [1 Migrating to meson](#) for migration information.

Basic concepts

Building an extension module which includes Python and Fortran consists of:

- Fortran source(s)
- One or more generated files from `f2py`
 - A C wrapper file is always created
 - Code with modules require an additional `.f90` wrapper
 - Code with functions generate an additional `.f` wrapper
- `fortranobject.{c,h}`
 - Distributed with `numpy`
 - Can be queried via `python -c "import numpy.f2py; print(numpy.f2py.get_include())"`
- NumPy headers
 - Can be queried via `python -c "import numpy; print(numpy.get_include())"`
- Python libraries and development headers

Broadly speaking there are three cases which arise when considering the outputs of `f2py`:

Fortran 77 programs

- Input file `blah.f`
- Generates
 - `blahmodule.c`
 - `blah-f2pywrappers.f`

When no `COMMON` blocks are present only a C wrapper file is generated. Wrappers are also generated to rewrite assumed shape arrays as automatic arrays.

Fortran 90 programs

- Input file `blah.f90`
- Generates:
 - `blahmodule.c`

- `blah-f2pywrappers.f`
- `blah-f2pywrappers2.f90`

The `f90` wrapper is used to handle code which is subdivided into modules. The `f` wrapper makes subroutines for functions. It rewrites assumed shape arrays as automatic arrays.

Signature files

- Input file `blah.pyf`
- Generates:
 - `blahmodule.c`
 - `blah-f2pywrappers2.f90` (occasionally)
 - `blah-f2pywrappers.f` (occasionally)

Signature files `.pyf` do not signal their language standard via the file extension, they may generate the F90 and F77 specific wrappers depending on their contents; which shifts the burden of checking for generated files onto the build system.

Changed in version NumPy: 1.22.4

`f2py` will deterministically generate wrapper files based on the input file Fortran standard (F77 or greater). `--skip-empty-wrappers` can be passed to `f2py` to restore the previous behaviour of only generating wrappers when needed by the input.

In theory keeping the above requirements in hand, any build system can be adapted to generate `f2py` extension modules. Here we will cover a subset of the more popular systems.

Note: `make` has no place in a modern multi-language setup, and so is not discussed further.

Build systems

Using via `meson`

Note: Much of this document is now obsoleted, one can run `f2py` with `--build-dir` to get a skeleton `meson` project with basic dependencies setup.

Changed in version 1.26.x: The default build system for `f2py` is now `meson`, see [Status of numpy.distutils and migration advice](#) for some more details..

Fibonacci walkthrough (F77)

We will need the generated C wrapper before we can use a general purpose build system like `meson`. We will acquire this by:

```
python -m numpy.f2py fib1.f -m fib2
```

Now, consider the following `meson.build` file for the `fib` and `scalar` examples from [Three ways to wrap - getting started](#) section:

```

project('f2py_examples', 'c',
        version : '0.1',
        license: 'BSD-3',
        meson_version: '>=0.64.0',
        default_options : ['warning_level=2'],
)

add_languages('fortran')

py_mod = import('python')
py = py_mod.find_installation(pure: false)
py_dep = py.dependency()

incdir_numpy = run_command(py,
    ['-c', 'import os; os.chdir(".."); import numpy; print(numpy.get_include())'],
    check : true
).stdout().strip()

incdir_f2py = run_command(py,
    ['-c', 'import os; os.chdir(".."); import numpy.f2py; print(numpy.f2py.get_
→include())'],
    check : true
).stdout().strip()

inc_np = include_directories(incdir_numpy, incdir_f2py)

py.extension_module('fib2',
[
    'fib1.f',
    'fib2module.c', # note: this assumes f2py was manually run before!
],
    incdir_f2py / 'fortranobject.c',
    include_directories: inc_np,
    dependencies : py_dep,
    install : true
)

```

At this point the build will complete, but the import will fail:

```

meson setup builddir
meson compile -C builddir
cd builddir
python -c 'import fib2'
Traceback (most recent call last):
File "<string>", line 1, in <module>
ImportError: fib2.cpython-39-x86_64-linux-gnu.so: undefined symbol: FIB_
# Check this isn't a false positive
nm -A fib2.cpython-39-x86_64-linux-gnu.so | grep FIB_
fib2.cpython-39-x86_64-linux-gnu.so: U FIB_

```

Recall that the original example, as reproduced below, was in SCREAMCASE:

```

C FILE: FIB1.F
    SUBROUTINE FIB(A,N)
C
C    CALCULATE FIRST N FIBONACCI NUMBERS
C

```

(continues on next page)

(continued from previous page)

```

INTEGER N
REAL*8 A(N)
DO I=1,N
  IF (I.EQ.1) THEN
    A(I) = 0.0D0
  ELSEIF (I.EQ.2) THEN
    A(I) = 1.0D0
  ELSE
    A(I) = A(I-1) + A(I-2)
  ENDIF
ENDDO
END
C END FILE FIB1.F

```

With the standard approach, the subroutine exposed to python is `fib` and not `FIB`. This means we have a few options. One approach (where possible) is to lowercase the original Fortran file with say:

```

tr "[:upper:]" "[:lower:]" < fib1.f > fib1.f
python -m numpy.f2py fib1.f -m fib2
meson --wipe builddir
meson compile -C builddir
cd builddir
python -c 'import fib2'

```

However this requires the ability to modify the source which is not always possible. The easiest way to solve this is to let `f2py` deal with it:

```

python -m numpy.f2py fib1.f -m fib2 --lower
meson --wipe builddir
meson compile -C builddir
cd builddir
python -c 'import fib2'

```

Automating wrapper generation

A major pain point in the workflow defined above, is the manual tracking of inputs. Although it would require more effort to figure out the actual outputs for reasons discussed in *F2PY and build systems*.

Note: From NumPy 1.22.4 onwards, `f2py` will deterministically generate wrapper files based on the input file Fortran standard (F77 or greater). `--skip-empty-wrappers` can be passed to `f2py` to restore the previous behaviour of only generating wrappers when needed by the input.

However, we can augment our workflow in a straightforward to take into account files for which the outputs are known when the build system is set up.

```

project('f2py_examples', 'c',
  version : '0.1',
  license: 'BSD-3',
  meson_version: '>=0.64.0',
  default_options : ['warning_level=2'],
)

add_languages('fortran')

```

(continues on next page)

(continued from previous page)

```

py_mod = import('python')
py = py_mod.find_installation(pure: false)
py_dep = py.dependency()

incdir_numpy = run_command(py,
    ['-c', 'import os; os.chdir(".."); import numpy; print(numpy.get_include())'],
    check : true
).stdout().strip()

incdir_f2py = run_command(py,
    ['-c', 'import os; os.chdir(".."); import numpy.f2py; print(numpy.f2py.get_
    ↪include())'],
    check : true
).stdout().strip()

fibby_source = custom_target('fibbymodule.c',
    input : ['fib1.f'], # .f so no F90 wrappers
    output : ['fibbymodule.c', 'fibby-f2pywrappers.f'],
    command : [py, '-m', 'numpy.f2py', '@INPUT@', '-m', 'fibby', '--lower']
)

inc_np = include_directories(incdir_numpy, incdir_f2py)

py.extension_module('fibby',
    ['fib1.f', fibby_source],
    incdir_f2py / 'fortranobject.c',
    include_directories: inc_np,
    dependencies : py_dep,
    install : true
)

```

This can be compiled and run as before.

```

rm -rf builddir
meson setup builddir
meson compile -C builddir
cd builddir
python -c "import numpy as np; import fibby; a = np.zeros(9); fibby.fib(a); print (a)"
# [ 0.  1.  1.  2.  3.  5.  8. 13. 21.]

```

Salient points

It is worth keeping in mind the following:

- It is not possible to use SCREAMCASE in this context, so either the contents of the `.f` file or the generated wrapper `.c` needs to be lowered to regular letters; which can be facilitated by the `--lower` option of `F2PY`

Distributing F2PY extensions with meson-python

The [Using via meson](#) page covers building F2PY extensions using raw `meson` commands. This page shows how to package those extensions into installable Python distributions (sdist and wheels) using `meson-python` as the PEP 517 build backend.

This is the recommended approach for distributing F2PY-wrapped Fortran code as a Python package on PyPI or for local `pip install` workflows.

Note: `meson-python` replaced `setuptools / numpy.distutils` as the standard way to build and distribute compiled extensions in the NumPy and SciPy ecosystem. See [Status of numpy.distutils and migration advice](#) for background.

Prerequisites

You need:

- A C compiler
- A Fortran compiler (`gfortran`, `ifort`, `ifx`, `flang-new`, etc.), if you use any Fortran code in your package
- Python ≥ 3.10
- `meson`, `meson-python`, and `numpy` (installed automatically during the build when listed in `build-system.requires`)

Minimal example

The project below wraps a Fortran `fib` subroutine into an importable Python package called `fib_wrapper`.

Project layout:

```
fib_wrapper/          # project root
├─ fib.f90             # Fortran source
├─ fib_wrapper/        # Python package directory
│   └─ __init__.py
├─ meson.build
└─ pyproject.toml
```

Fortran source

Save the following as `fib.f90`:

```
subroutine fib(a, n)
  use iso_c_binding
  integer(c_int), intent(in) :: n
  integer(c_int), intent(out) :: a(n)
  integer :: i
  do i = 1, n
    if (i == 1) then
      a(i) = 0
    else if (i == 2) then
```

(continues on next page)

(continued from previous page)

```

        a(i) = 1
    else
        a(i) = a(i - 1) + a(i - 2)
    end if
end do
end subroutine fib

```

pyproject.toml

```

[build-system]
# numpy>=2.0 is required for dependency('numpy') support in meson.build
requires = ["meson-python>=0.15.0", "numpy>=2.0"]
build-backend = "mesonpy"

[project]
name = "fib_wrapper"
version = "0.1.0"
requires-python = ">=3.10"
dependencies = ["numpy"]

```

Two entries matter here:

- `build-backend = "mesonpy"` tells build frontends to use `meson-python`.
- `requires` lists build-time dependencies. `numpy >= 2.0` is required so that `f2py`, the NumPy headers, and `dependency('numpy')` support in Meson are available during compilation.

meson.build

```

project('fib_wrapper', 'c',
    version : '0.1.0',
    meson_version: '>=1.1.0',
    default_options : ['warning_level=2'],
)

add_languages('fortran', native: false)

py = import('python').find_installation(pure: false)

# NumPy >=2.0 provides include dirs via dependency()
np_dep = dependency('numpy')

incdir_f2py = run_command(py,
    ['-c', 'import numpy.f2py; print(numpy.f2py.get_include())'],
    check : true
).stdout().strip()

# f2py include dir (for fortranobject.h) is not in dependency('numpy'),
# so add it separately
f2py_dep = declare_dependency(
    include_directories : incdir_f2py,
)

```

(continues on next page)

(continued from previous page)

```
# Generate the f2py wrappers
fib_source = custom_target('fibmodule.c',
    input : ['fib.f90'],
    output : ['fibmodule.c', 'fib-f2pywrappers.f'],
    command : [py, '-m', 'numpy.f2py', '@INPUT@', '-m', 'fib', '--lower']
)

py.extension_module('fib',
    ['fib.f90', fib_source, incdir_f2py / 'fortranobject.c'],
    dependencies : [np_dep, f2py_dep],
    subdir: 'fib_wrapper',
    install : true,
)

# Install the Python package files
py.install_sources(
    'fib_wrapper/__init__.py',
    subdir: 'fib_wrapper',
)
```

Note: The file is stored as `meson_mesonpy.build` in the documentation source tree to avoid collisions with other examples. In your project, name it `meson.build`.

The `meson.build` file does four things:

1. Uses `dependency('numpy')` to locate NumPy headers, and a `declare_dependency` to add the F2PY include directory (for `fortranobject.h`).
2. Runs `f2py` via `custom_target` to generate the C wrapper sources.
3. Compiles the generated C code together with the Fortran source into a Python extension module using `py.extension_module`.
4. Installs `__init__.py` into the package directory so the result is a proper Python package.

The `subdir: 'fib_wrapper'` argument on the extension module is required so that the compiled `fib` shared library is installed inside the `fib_wrapper/` package directory, next to `__init__.py`. Without it the extension would be installed at the top level and `import fib_wrapper` would not find the `fib` extension. The resulting installed layout is:

```
site-packages/
└─ fib_wrapper/
   └─ __init__.py      # from .fib import fib
   └─ fib.cpython-*.so # compiled extension module
```

`__init__.py`

A minimal `__init__.py` re-exports the wrapped function:

```
from .fib import fib
```

Building and installing

Editable install (development)

```
pip install --no-build-isolation --editable .
```

`--no-build-isolation` reuses the current environment, which is useful when iterating. This requires `meson-python`, `meson`, `ninja`, and `numpy` to already be installed.

Building a wheel

```
# If you don't yet have `pypa/build` installed: `pip install build`
python -m build --wheel
```

The resulting `.whl` file in `dist/` can be uploaded to PyPI, or installed elsewhere with `pip install dist/fib_wrapper-0.1.0-*.whl`.

Verifying the install

```
>>> from fib_wrapper import fib
>>> fib(10)
array([ 0,  1,  1,  2,  3,  5,  8, 13, 21, 34], dtype=int32)
```

Customizing the Fortran compiler

`meson-python` delegates compiler selection to `meson`. By default, `meson` will choose the first Fortran compiler it finds on the `PATH`. If you want more control over Fortran compiler selection, set the `FC` environment variable before building:

```
FC=ifx python -m build --wheel
```

For more control, use a [Meson native file](#):

```
; native.ini
[binaries]
fortran = 'ifx'
c = 'icx'
```

```
python -m build --wheel -Csetup-args="--native-file=native.ini"
```

Adding dependencies (BLAS, LAPACK, etc.)

Use `dependency()` in `meson.build` to link against system libraries:

```
lapack_dep = dependency('lapack')

py.extension_module('mymod',
    [sources, generated, incdir_f2py / 'fortranobject.c'],
    dependencies : [np_dep, f2py_dep, lapack_dep],
    install : true,
)
```

`meson` resolves dependencies through `pkg-config`, `CMake`, or its own detection logic. See the [Meson dependency documentation](#) for details.

Differences from the `scikit-build-core` workflow

The `scikit-build-core` approach documented in *Using via `scikit-build`* uses `CMake` under the hood. `meson-python` provides:

- Native Fortran compiler support in `meson` (no `CMake` layer).
- Direct integration with `pip / build` via PEP 517.
- The same build system used by NumPy and SciPy themselves.

Further reading

- [meson-python documentation](#)
- [Meson build system](#)
- [SciPy's meson build configuration](#) (real-world F2PY usage)
- *Using via `meson`* (raw `meson` build without `meson-python`)
- *Using via `scikit-build`* (alternative using `scikit-build-core / CMake`)
- *1 Migrating to `meson`* (migration from `distutils`)

Using via `cmake`

In terms of complexity, `cmake` falls between `make` and `meson`. The learning curve is steeper since `CMake` syntax is not pythonic and is closer to `make` with environment variables.

However, the trade-off is enhanced flexibility and support for most architectures and compilers. An introduction to the syntax is out of scope for this document, but this [extensive CMake collection](#) of resources is great.

Note: `cmake` is very popular for mixed-language systems, however support for `f2py` is not particularly native or pleasant; and a more natural approach is to consider *Using via `scikit-build`*

Fibonacci walkthrough (F77)

Returning to the `fib` example from *Three ways to wrap - getting started* section.

```
C FILE: FIB1.F
    SUBROUTINE FIB(A,N)
C
C    CALCULATE FIRST N FIBONACCI NUMBERS
C
    INTEGER N
    REAL*8 A(N)
    DO I=1,N
        IF (I.EQ.1) THEN
            A(I) = 0.0D0
        ELSEIF (I.EQ.2) THEN
            A(I) = 1.0D0
        ELSE
            A(I) = A(I-1) + A(I-2)
        ENDIF
    ENDDO
    END
C END FILE FIB1.F
```

We do not need to explicitly generate the `python -m numpy.f2py fib1.f` output, which is `fib1module.c`, which is beneficial. With this; we can now initialize a `CMakeLists.txt` file as follows:

```
cmake_minimum_required(VERSION 3.18) # Needed to avoid requiring embedded Python libs_
↳ too

project(fibby
  VERSION 1.0
  DESCRIPTION "FIB module"
  LANGUAGES C Fortran
)

# Safety net
if(PROJECT_SOURCE_DIR STREQUAL PROJECT_BINARY_DIR)
  message(
    FATAL_ERROR
    "In-source builds not allowed. Please make a new directory (called a build_
↳ directory) and run CMake from there.\n"
  )
endif()

# Grab Python, 3.8 or newer
find_package(Python 3.8 REQUIRED
  COMPONENTS Interpreter Development.Module NumPy)

# Grab the variables from a local Python installation
# F2PY headers
execute_process(
  COMMAND "${Python_EXECUTABLE}"
  -c "import numpy.f2py; print(numpy.f2py.get_include())"
  OUTPUT_VARIABLE F2PY_INCLUDE_DIR
  OUTPUT_STRIP_TRAILING_WHITESPACE
)
```

(continues on next page)

(continued from previous page)

```

# Print out the discovered paths
include(CMakePrintHelpers)
cmake_print_variables(Python_INCLUDE_DIRS)
cmake_print_variables(F2PY_INCLUDE_DIR)
cmake_print_variables(Python_NumPy_INCLUDE_DIRS)

# Common variables
set(f2py_module_name "fibby")
set(fortran_src_file "${CMAKE_SOURCE_DIR}/fib1.f")
set(f2py_module_c "${f2py_module_name}.c")

# Generate sources
add_custom_target(
    genpyf
    DEPENDS "${CMAKE_CURRENT_BINARY_DIR}/${f2py_module_c}"
)
add_custom_command(
    OUTPUT "${CMAKE_CURRENT_BINARY_DIR}/${f2py_module_c}"
    COMMAND ${Python_EXECUTABLE} -m "numpy.f2py"
        "${fortran_src_file}"
        -m "fibby"
        --lower # Important
    DEPENDS fib1.f # Fortran source
)

# Set up target
Python_add_library(${CMAKE_PROJECT_NAME} MODULE WITH_SOABI
    "${CMAKE_CURRENT_BINARY_DIR}/${f2py_module_c}" # Generated
    "${F2PY_INCLUDE_DIR}/fortranobject.c" # From NumPy
    "${fortran_src_file}" # Fortran source(s)
)

# Depend on sources
target_link_libraries(${CMAKE_PROJECT_NAME} PRIVATE Python::NumPy)
add_dependencies(${CMAKE_PROJECT_NAME} genpyf)
target_include_directories(${CMAKE_PROJECT_NAME} PRIVATE "${F2PY_INCLUDE_DIR}")

```

A key element of the `CMakeLists.txt` file defined above is that the `add_custom_command` is used to generate the wrapper C files and then added as a dependency of the actual shared library target via a `add_custom_target` directive which prevents the command from running every time. Additionally, the method used for obtaining the `fortranobject.c` file can also be used to grab the numpy headers on older cmake versions.

This then works in the same manner as the other modules, although the naming conventions are different and the output library is not automatically prefixed with the `cython` information.

```

ls .
# CMakeLists.txt fib1.f
cmake -S . -B build
cmake --build build
cd build
python -c "import numpy as np; import fibby; a = np.zeros(9); fibby.fib(a); print (a)"
# [ 0.  1.  1.  2.  3.  5.  8. 13. 21.]

```

This is particularly useful where an existing toolchain already exists and `scikit-build` or other additional python dependencies are discouraged.

Using via `scikit-build`

`scikit-build` provides two separate concepts geared towards the users of Python extension modules.

1. A `setuptools` replacement (legacy behaviour)
2. A series of `cmake` modules with definitions which help building Python extensions

Note: It is possible to use `scikit-build`'s `cmake` modules to [bypass the `cmake` setup mechanism](#) completely, and to write targets which call `f2py -c`. This usage is **not recommended** since the point of these build system documents are to move away from the internal `numpy.distutils` methods.

For situations where no `setuptools` replacements are required or wanted (i.e. if wheels are not needed), it is recommended to instead use the vanilla `cmake` setup described in [Using via `cmake`](#).

Fibonacci walkthrough (F77)

We will consider the `fib` example from [Three ways to wrap - getting started](#) section.

```
C FILE: FIB1.F
    SUBROUTINE FIB(A,N)
C
C    CALCULATE FIRST N FIBONACCI NUMBERS
C
    INTEGER N
    REAL*8 A(N)
    DO I=1,N
        IF (I.EQ.1) THEN
            A(I) = 0.0D0
        ELSEIF (I.EQ.2) THEN
            A(I) = 1.0D0
        ELSE
            A(I) = A(I-1) + A(I-2)
        ENDIF
    ENDDO
    END
C END FILE FIB1.F
```

CMake modules only

Consider using the following `CMakeLists.txt`.

```
### setup project ###
cmake_minimum_required(VERSION 3.9)

project(fibby
  VERSION 1.0
  DESCRIPTION "FIB module"
  LANGUAGES C Fortran
)

# Safety net
if(PROJECT_SOURCE_DIR STREQUAL PROJECT_BINARY_DIR)
```

(continues on next page)

(continued from previous page)

```

message(
  FATAL_ERROR
  "In-source builds not allowed. Please make a new directory (called a build_
↪directory) and run CMake from there.\n"
)
endif()

# Ensure scikit-build modules
if (NOT SKBUILD)
  find_package(PythonInterp 3.8 REQUIRED)
  # Kanged --> https://github.com/Kitware/torch_liberator/blob/master/CMakeLists.txt
  # If skbuild is not the driver; include its utilities in CMAKE_MODULE_PATH
  execute_process(
    COMMAND "${PYTHON_EXECUTABLE}"
    -c "import os, skbuild; print(os.path.dirname(skbuilt.__file__))"
    OUTPUT_VARIABLE SKBLD_DIR
    OUTPUT_STRIP_TRAILING_WHITESPACE
  )
  list(APPEND CMAKE_MODULE_PATH "${SKBLD_DIR}/resources/cmake")
  message(STATUS "Looking in ${SKBLD_DIR}/resources/cmake for CMake modules")
endif()

# scikit-build style includes
find_package(PythonExtensions REQUIRED) # for ${PYTHON_EXTENSION_MODULE_SUFFIX}

# Grab the variables from a local Python installation
# NumPy headers
execute_process(
  COMMAND "${PYTHON_EXECUTABLE}"
  -c "import numpy; print(numpy.get_include())"
  OUTPUT_VARIABLE NumPy_INCLUDE_DIRS
  OUTPUT_STRIP_TRAILING_WHITESPACE
)
# F2PY headers
execute_process(
  COMMAND "${PYTHON_EXECUTABLE}"
  -c "import numpy.f2py; print(numpy.f2py.get_include())"
  OUTPUT_VARIABLE F2PY_INCLUDE_DIR
  OUTPUT_STRIP_TRAILING_WHITESPACE
)

# Prepping the module
set(f2py_module_name "fibby")
set(fortran_src_file "${CMAKE_SOURCE_DIR}/fib1.f")
set(f2py_module_c "${f2py_module_name}.module.c")

# Target for enforcing dependencies
add_custom_target(genpyf
  DEPENDS "${fortran_src_file}"
)
add_custom_command(
  OUTPUT "${CMAKE_CURRENT_BINARY_DIR}/${f2py_module_c}"
  COMMAND ${PYTHON_EXECUTABLE} -m "numpy.f2py"
    "${fortran_src_file}"
    -m "fibby"
    --lower # Important
  DEPENDS fib1.f # Fortran source

```

(continues on next page)

(continued from previous page)

```

)

add_library(${CMAKE_PROJECT_NAME} MODULE
    "${f2py_module_name}module.c"
    "${F2PY_INCLUDE_DIR}/fortranobject.c"
    "${fortran_src_file}")

target_include_directories(${CMAKE_PROJECT_NAME} PUBLIC
    ${F2PY_INCLUDE_DIR}
    ${NumPy_INCLUDE_DIRS}
    ${PYTHON_INCLUDE_DIRS})

set_target_properties(${CMAKE_PROJECT_NAME} PROPERTIES SUFFIX "${PYTHON_EXTENSION_
↪MODULE_SUFFIX}")
set_target_properties(${CMAKE_PROJECT_NAME} PROPERTIES PREFIX "")

# Linker fixes
if (UNIX)
    if (APPLE)
        set_target_properties(${CMAKE_PROJECT_NAME} PROPERTIES
            LINK_FLAGS '-Wl,-dylib,-undefined,dynamic_lookup')
    else()
        set_target_properties(${CMAKE_PROJECT_NAME} PROPERTIES
            LINK_FLAGS '-Wl,--allow-shlib-undefined')
    endif()
endif()

add_dependencies(${CMAKE_PROJECT_NAME} genpyf)

install(TARGETS ${CMAKE_PROJECT_NAME} DESTINATION fibby)

```

Much of the logic is the same as in *Using via cmake*, however notably here the appropriate module suffix is generated via `sysconfig.get_config_var("SO")`. The resulting extension can be built and loaded in the standard workflow.

```

ls .
# CMakeLists.txt fib1.f
cmake -S . -B build
cmake --build build
cd build
python -c "import numpy as np; import fibby; a = np.zeros(9); fibby.fib(a); print (a)"
# [ 0.  1.  1.  2.  3.  5.  8. 13. 21.]

```

setuptools replacement

Note: As of November 2021

The behavior described here of driving the `cmake` build of a module is considered to be legacy behaviour and should not be depended on.

The utility of `scikit-build` lies in being able to drive the generation of more than extension modules, in particular a common usage pattern is the generation of Python distributables (for example for PyPI).

The workflow with `scikit-build` straightforwardly supports such packaging requirements. Consider augmenting the project with a `setup.py` as defined:

```
from skbuild import setup

setup(
    name="fibby",
    version="0.0.1",
    description="a minimal example package (fortran version)",
    license="MIT",
    packages=['fibby'],
    python_requires=">=3.7",
)
```

Along with a commensurate `pyproject.toml`

```
[build-system]
requires = ["setuptools>=42", "wheel", "scikit-build", "cmake>=3.9", "numpy>=1.21"]
build-backend = "setuptools.build_meta"
```

Together these can build the extension using `cmake` in tandem with other standard `setuptools` outputs. Running `cmake` through `setup.py` is mostly used when it is necessary to integrate with extension modules not built with `cmake`.

```
ls .
# CMakeLists.txt fib1.f pyproject.toml setup.py
python setup.py build_ext --inplace
python -c "import numpy as np; import fibby.fibby; a = np.zeros(9); fibby.fibby.
→fib(a); print (a)"
# [ 0.  1.  1.  2.  3.  5.  8. 13. 21.]
```

Where we have modified the path to the module as `--inplace` places the extension module in a subfolder.

1 Migrating to meson

As per the timeline laid out in *Status of numpy.distutils and migration advice*, `distutils` has been removed. This page collects common workflows.

Note: This is a **living** document, [pull requests](#) are very welcome!

1.1 Baseline

We will start out with a slightly modern variation of the classic Fibonacci series generator.

```
! fib.f90
subroutine fib(a, n)
  use iso_c_binding
  integer(c_int), intent(in) :: n
  integer(c_int), intent(out) :: a(n)
  do i = 1, n
    if (i .eq. 1) then
      a(i) = 0.0d0
    elseif (i .eq. 2) then
      a(i) = 1.0d0
    else
      a(i) = a(i - 1) + a(i - 2)
    end if
  end do
end subroutine
```

(continues on next page)

(continued from previous page)

```

        end if
    end do
end

```

This will not win any awards, but can be a reasonable starting point.

1.2 Compilation options

1.2.1 Basic Usage

```

python -m numpy.f2py -c fib.f90 -m fib
> python -c "import fib; print(fib.fib(30))"
[  0   1   1   2   3   5   8   13   21   34
  55   89  144  233  377  610  987 1597 2584 4181
 6765 10946 17711 28657 46368 75025 121393 196418 317811 514229]

```

1.2.2 Specify the backend

```
python -m numpy.f2py -c fib.f90 -m fib
```

This is the only option. There used to be a `distutils` backend but it was removed in NumPy2.5.0.

1.2.3 Pass a compiler name

```
FC=gfortran python -m numpy.f2py -c fib.f90 -m fib
```

Native files can also be used.

Similarly, `CC` can be used in both cases to set the C compiler. Since the environment variables are generally pretty common across both, so a small sample is included below.

Name	What
FC	Fortran compiler
CC	C compiler
CFLAGS	C compiler options
FFLAGS	Fortran compiler options
LDFLAGS	Linker options
LD_LIBRARY_PATH	Library file locations (Unix)
LIBS	Libraries to link against
PATH	Search path for executables
CXX	C++ compiler
CXXFLAGS	C++ compiler options

Note: For Windows, these may not work very reliably, so [native files](#) are likely the best bet, or by direct [1.3 Customizing builds](#).

1.2.4 Dependencies

```
python -m numpy.f2py -c fib.f90 -m fib --dep lapack
```

This maps to `dependency("lapack")` and so can be used for a wide variety of dependencies. They can be [customized further](#) to use CMake or other systems to resolve dependencies.

1.2.5 Libraries

meson is capable of linking against libraries.

```
python -m numpy.f2py -c fib.f90 -m fib -lmylib -L/path/to/mylib
```

1.3 Customizing builds

```
python -m numpy.f2py -c fib.f90 -m fib --build-dir blah
```

The resulting build can be customized via the [Meson Build How-To Guide](#). In fact, the resulting set of files can even be committed directly and used as a meson subproject in a separate codebase.

Advanced F2PY use cases

Adding user-defined functions to F2PY generated modules

User-defined Python C/API functions can be defined inside signature files using `usercode` and `pymethoddef` statements (they must be used inside the `python module` block). For example, the following signature file `spam.pyf`

```
!    -*- f90 -*-
python module spam
  usercode '''
    static char doc_spam_system[] = "Execute a shell command.";
    static PyObject *spam_system(PyObject *self, PyObject *args)
    {
        char *command;
        int sts;

        if (!PyArg_ParseTuple(args, "s", &command))
            return NULL;
        sts = system(command);
        return Py_BuildValue("i", sts);
    }
    '''
  pymethoddef '''
    {"system",  spam_system, METH_VARARGS, doc_spam_system},
    '''
end python module spam
```

wraps the C library function `system()`:

```
f2py -c spam.pyf
```

In Python this can then be used as:

```
>>> import spam
>>> status = spam.system('whoami')
pearu
>>> status = spam.system('blah')
sh: line 1: blah: command not found
```

Adding user-defined variables

The following example illustrates how to add user-defined variables to a F2PY generated extension module by modifying the dictionary of a F2PY generated module. Consider the following signature file (compiled with `f2py -c var.pyf`):

```
!      -*- f90 -*-
python module var
  usercode '''
    int BAR = 5;
  '''
  interface
    usercode '''
      PyDict_SetItemString(d, "BAR", PyLong_FromLong(BAR));
    '''
  end interface
end python module
```

Notice that the second `usercode` statement must be defined inside an `interface` block and the module dictionary is available through the variable `d` (see `varmodule.c` generated by `f2py var.pyf` for additional details).

Usage in Python:

```
>>> import var
>>> var.BAR
5
```

Dealing with KIND specifiers

Currently, F2PY can handle only `<type spec>(kind=<kindselector>)` declarations where `<kindselector>` is a numeric integer (e.g. 1, 2, 4,...), but not a function call `KIND(...)` or any other expression. F2PY needs to know what would be the corresponding C type and a general solution for that would be too complicated to implement.

However, F2PY provides a hook to overcome this difficulty, namely, users can define their own `<Fortran type>` to `<C type>` maps. For example, if Fortran 90 code contains:

```
REAL(kind=KIND(0.0D0)) ...
```

then create a mapping file containing a Python dictionary:

```
{ 'real': { 'KIND(0.0D0)': 'double' } }
```

for instance.

Use the `--f2cmap` command-line option to pass the file name to F2PY. By default, F2PY assumes file name is `.f2py_f2cmap` in the current working directory.

More generally, the `f2cmap` file must contain a dictionary with items:

```
<Fortran typespec> : {<selector_expr>:<C type>}
```

that defines mapping between Fortran type:

```
<Fortran typespec>([kind=]<selector_expr>)
```

and the corresponding <C type>. The <C type> can be one of the following:

```
double
float
long_double
char
signed_char
unsigned_char
short
unsigned_short
int
long
long_long
unsigned
complex_float
complex_double
complex_long_double
string
```

For example, for a Fortran file `func1.f` containing:

```
subroutine func1(n, x, res)
  use, intrinsic :: iso_fortran_env, only: int64, real64
  implicit none
  integer(int64), intent(in) :: n
  real(real64), intent(in) :: x(n)
  real(real64), intent(out) :: res
Cf2py  intent(hide) :: n
       res = sum(x)
end
```

In order to convert `int64` and `real64` to valid C data types, a `.f2py_f2cmap` file with the following content can be created in the current directory:

```
dict(real=dict(real64='double'), integer=dict(int64='long long'))
```

and create the module as usual. F2PY checks if a `.f2py_f2cmap` file is present in the current directory and will use it to map `KIND` specifiers to C data types.

```
f2py -c func1.f -m func1
```

Alternatively, the mapping file can be saved with any other name, for example `mapfile.txt`, and this information can be passed to F2PY by using the `--f2cmap` option.

```
f2py -c func1.f -m func1 --f2cmap mapfile.txt
```

For more information, see F2PY source code `numpy/f2py/capi_maps.py`.

Character strings

Assumed length character strings

In Fortran, assumed length character string arguments are declared as `character*(*)` or `character(len=*)`, that is, the length of such arguments are determined by the actual string arguments at runtime. For `intent(in)` arguments, this lack of length information poses no problems for f2py to construct functional wrapper functions. However, for `intent(out)` arguments, the lack of length information is problematic for f2py generated wrappers because there is no size information available for creating memory buffers for such arguments and F2PY assumes the length is 0. Depending on how the length of assumed length character strings are specified, there exist ways to workaround this problem, as exemplified below.

If the length of the `character*(*)` output argument is determined by the state of other input arguments, the required connection can be established in a signature file or within a f2py-comment by adding an extra declaration for the corresponding argument that specifies the length in character selector part. For example, consider a Fortran file `asterisk1.f90`:

```
subroutine foo1(s)
  character*(*), intent(out) :: s
  !f2py character(f2py_len=12) s
  s = "123456789A12"
end subroutine foo1
```

Compile it with `f2py -c asterisk1.f90 -m asterisk1` and then in Python:

```
>>> import asterisk1
>>> asterisk1.foo1()
b'123456789A12'
```

Notice that the extra declaration `character(f2py_len=12) s` is interpreted only by f2py and in the `f2py_len=` specification one can use C-expressions as a length value.

In the following example:

```
subroutine foo2(s, n)
  character(len=*), intent(out) :: s
  integer, intent(in) :: n
  !f2py character(f2py_len=n), depend(n) :: s
  s = "123456789A123456789B"(1:n)
end subroutine foo2
```

the length of the output assumed length string depends on an input argument `n`, after wrapping with F2PY, in Python:

```
>>> import asterisk
>>> asterisk.foo2(2)
b'12'
>>> asterisk.foo2(12)
b'123456789A12'
>>>
```

Boilerplate reduction and templating

Using FYPP for binding generic interfaces

`f2py` doesn't currently support binding interface blocks. However, there are workarounds in use. Perhaps the best known is the usage of `tempita` for using `.pyf.src` files as is done in the bindings which are part of `scipy`. `tempita` support has been removed and is no longer recommended in any case.

Note: The reason interfaces cannot be supported within `f2py` itself is because they don't correspond to exported symbols in compiled libraries.

```
> nm gen.o
00000000000000078 T __add_mod_MOD_add_complex
00000000000000000 T __add_mod_MOD_add_complex_dp
00000000000000150 T __add_mod_MOD_add_integer
00000000000000124 T __add_mod_MOD_add_real
000000000000000ee T __add_mod_MOD_add_real_dp
```

Here we will discuss a few techniques to leverage `f2py` in conjunction with `fypp` to emulate generic interfaces and to ease the binding of multiple (similar) functions.

Basic example: Addition module

Let us build on the example (from the user guide, *F2PY examples*) of a subroutine which takes in two arrays and returns its sum.

```
C
    SUBROUTINE ZADD (A,B,C,N)
C
    DOUBLE COMPLEX A(*)
    DOUBLE COMPLEX B(*)
    DOUBLE COMPLEX C(*)
    INTEGER N
    DO 20 J = 1, N
        C(J) = A(J) + B(J)
20  CONTINUE
    END
```

We will recast this into modern fortran:

```
module adder
    implicit none
contains

    subroutine zadd(a, b, c, n)
        integer, intent(in) :: n
        double complex, intent(in) :: a(n), b(n)
        double complex, intent(out) :: c(n)
        integer :: j
        do j = 1, n
            c(j) = a(j) + b(j)
        end do
    end subroutine zadd
```

(continues on next page)

(continued from previous page)

```
end module adder
```

We could go on as in the original example, adding intents by hand among other things, however in production often there are other concerns. For one, we can template via FYPP the construction of similar functions:

```
module adder
  implicit none
  contains

  #:def add_subroutine(dtype_prefix, dtype)
    subroutine ${dtype_prefix}$add(a, b, c, n)
      integer, intent(in) :: n
      ${dtype}$, intent(in) :: a(n), b(n)
      ${dtype}$ :: c(n)
      integer :: j
      do j = 1, n
        c(j) = a(j) + b(j)
      end do
    end subroutine ${dtype_prefix}$add

  #:enddef

  #:for dtype_prefix, dtype in [('i', 'integer'), ('s', 'real'), ('d', 'real(kind=8)'),
  ↪ ('c', 'complex'), ('z', 'double complex')]
    @:add_subroutine(${dtype_prefix}$, ${dtype}$)
  #:endfor

end module adder
```

This can be pre-processed to generate the full fortran code:

```
› fypp gen_adder.f90.fypp > adder.f90
```

As to be expected, this can be wrapped by f2py subsequently.

Now we will consider maintaining the bindings in a separate file. Note the following basic .pyf which can be generated for a single subroutine via `f2py -m adder adder_base.f90 -h adder.pyf`:

```
!      -*- f90 -*-
! Note: the context of this file is case sensitive.

python module adder ! in
  interface ! in :adder
    module adder ! in :adder:adder_base.f90
      subroutine zadd(a,b,c,n) ! in :adder:adder_base.f90:adder
        double complex dimension(n),intent(in) :: a
        double complex dimension(n),intent(in),depend(n) :: b
        double complex dimension(n),intent(out),depend(n) :: c
        integer, optional,intent(in),check(shape(a, 0) == n),depend(a) :: n
        ↪n=shape(a, 0)
      end subroutine zadd
    end module adder
  end interface
end python module adder

! This file was auto-generated with f2py (version:2.0.0.dev0+git20240101.bab7280).
```

(continues on next page)

(continued from previous page)

```
! See:
! https://web.archive.org/web/20140822061353/http://cens.ioc.ee/projects/f2py2e
```

With the docstring:

```
c = zadd(a,b,[n])

Wrapper for ``zadd``.

Parameters
-----
a : input rank-1 array('D') with bounds (n)
b : input rank-1 array('D') with bounds (n)

Other Parameters
-----
n : input int, optional
    Default: shape(a, 0)

Returns
-----
c : rank-1 array('D') with bounds (n)
```

Which is already pretty good. However, `n` should never be passed in the first place so we will make some minor adjustments.

```
!      -*- f90 -*-
! Note: the context of this file is case sensitive.

python module adder ! in
  interface ! in :adder
    module adder ! in :adder:adder_base.f90
      subroutine zadd(a,b,c,n) ! in :adder:adder_base.f90:adder
        integer intent (hide), depend(a) :: n=len(a)
        double complex dimension(n), intent (in) :: a
        double complex dimension(n), intent (in), depend(n) :: b
        double complex dimension(n), intent (out), depend(n) :: c
      end subroutine zadd
    end module adder
  end interface
end python module adder

! This file was auto-generated with f2py (version:2.0.0.dev0+git20240101.bab7280).
! See:
! https://numpy.org/doc/stable/f2py/
```

Which corresponds to:

```
In [3]: ?adder.adder.zadd
Call signature: adder.adder.zadd(*args, **kwargs)
Type:          fortran
String form:    <fortran function zadd>
Docstring:
c = zadd(a,b)

Wrapper for ``zadd``.
```

(continues on next page)

(continued from previous page)

Parameters

```

a : input rank-1 array('D') with bounds (n)
b : input rank-1 array('D') with bounds (n)

```

Returns

```

c : rank-1 array('D') with bounds (n)

```

Finally, we can template over this in a similar manner, to attain the original goal of having bindings which make use of `f2py` directives and have minimal spurious repetition.

```

!      -*- f90 -*-
! Note: the context of this file is case sensitive.

python module adder ! in
  interface ! in :adder
    module adder ! in :adder:adder_base.f90
# :def add_subroutine(dtype_prefix, dtype)
      subroutine ${dtype_prefix}$add(a,b,c,n) ! in :adder:adder_base.f90:adder
        integer intent(hide),depend(a) :: n=len(a)
        ${dtype}$ dimension(n),intent(in) :: a
        ${dtype}$ dimension(n),intent(in),depend(n) :: b
        ${dtype}$ dimension(n),intent(out),depend(n) :: c
      end subroutine ${dtype_prefix}$add
# :enddef

# :for dtype_prefix, dtype in [('i', 'integer'), ('s', 'real'), ('d', 'real(kind=8)'),
↪ ('c', 'complex'), ('z', 'complex(kind=8)')]
    @:add_subroutine(${dtype_prefix}$, ${dtype}$)
# :endfor
  end module adder
end interface
end python module adder

! This file was auto-generated with f2py (version:2.0.0.dev0+git20240101.bab7280).
! See:
! https://numpy.org/doc/stable/f2py/

```

Usage boils down to:

```

fyp gen_adder.f90.fyp > adder.f90
fyp adder.pyf.fyp > adder.pyf
f2py -m adder -c adder.pyf adder.f90 --backend meson

```

F2PY test suite

F2PY's test suite is present in the directory `numpy/f2py/tests`. Its aim is to ensure that Fortran language features are correctly translated to Python. For example, the user can specify starting and ending indices of arrays in Fortran. This behaviour is translated to the generated CPython library where the arrays strictly start from 0 index.

The directory of the test suite looks like the following:

```
./tests/
├── __init__.py
├── src
│   ├── abstract_interface
│   ├── array_from_pyobj
│   ├── // ... several test folders
│   └── string
├── test_abstract_interface.py
├── test_array_from_pyobj.py
├── // ... several test files
├── test_symbolic.py
└── util.py
```

Files starting with `test_` contain tests for various aspects of `f2py` from parsing Fortran files to checking modules' documentation. `src` directory contains the Fortran source files upon which we do the testing. `util.py` contains utility functions for building and importing Fortran modules during test time using a temporary location.

Adding a test

F2PY's current test suite predates `pytest` and therefore does not use fixtures. Instead, the test files contain test classes that inherit from `F2PyTest` class present in `util.py`.

```
1  backend = SimplifiedMesonBackend(
2      module_name=module_name,
3      sources=source_files,
4      extra_objects=kwargs.get("extra_objects", []),
5      build_dir=build_dir,
6      include_dirs=kwargs.get("include_dirs", []),
7      library_dirs=kwargs.get("library_dirs", []),
8      libraries=kwargs.get("libraries", []),
9      define_macros=kwargs.get("define_macros", []),
10     undef_macros=kwargs.get("undef_macros", []),
```

This class many helper functions for parsing and compiling test source files. Its child classes can override its `sources` data member to provide their own source files. This superclass will then compile the added source files upon object creation and their functions will be appended to `self.module` data member. Thus, the child classes will be able to access the fortran functions specified in source file by calling `self.module.[fortran_function_name]`.

New in version v2.0.0b1.

Each of the `f2py` tests should run without failure if no Fortran compilers are present on the host machine. To facilitate this, the `CompilerChecker` is used, essentially providing a `meson` dependent set of utilities namely `has_{c, f77, f90, fortran}_compiler()`.

For the CLI tests in `test_f2py2e`, flags which are expected to call `meson` or otherwise depend on a compiler need to call `compiler_check_f2pycli()` instead of `f2pycli()`.

Example

Consider the following subroutines, contained in a file named `add-test.f`

```
subroutine addb(k)
  real(8), intent(inout) :: k(:)
  k=k+1
endsubroutine

subroutine addc(w,k)
  real(8), intent(in) :: w(:)
  real(8), intent(out) :: k(size(w))
  k=w+1
endsubroutine
```

The first routine *addb* simply takes an array and increases its elements by 1. The second subroutine *addc* assigns a new array *k* with elements greater than the elements of the input array *w* by 1.

A test can be implemented as follows:

```
class TestAdd(util.F2PyTest):
    sources = [util.getpath("add-test.f")]

    def test_module(self):
        k = np.array([1, 2, 3], dtype=np.float64)
        w = np.array([1, 2, 3], dtype=np.float64)
        self.module.addb(k)
        assert np.allclose(k, w + 1)
        self.module.addc([w, k])
        assert np.allclose(k, w + 1)
```

We override the `sources` data member to provide the source file. The source files are compiled and subroutines are attached to module data member when the class object is created. The `test_module` function calls the subroutines and tests their results.

F2PY and Windows

Warning: F2PY support for Windows is not always at par with Linux support

Note: [SciPy's documentation](#) has some information on system-level dependencies which are well tested for Fortran as well.

Broadly speaking, there are two issues working with F2PY on Windows:

- the lack of actively developed FOSS Fortran compilers, and,
- the linking issues related to the C runtime library for building Python-C extensions.

The focus of this section is to establish a guideline for developing and extending Fortran modules for Python natively, via F2PY on Windows.

Currently supported toolchains are:

- Mingw-w64 C/C++/Fortran compilers
- Intel compilers

- Clang-cl + Flang
- MSVC + Flang

Overview

From a user perspective, the most UNIX compatible Windows development environment is through emulation, either via the Windows Subsystem on Linux, or facilitated by Docker. In a similar vein, traditional virtualization methods like VirtualBox are also reasonable methods to develop UNIX tools on Windows.

Native Windows support is typically stunted beyond the usage of commercial compilers. However, as of 2022, most commercial compilers have free plans which are sufficient for general use. Additionally, the Fortran language features supported by `f2py` (partial coverage of Fortran 2003), means that newer toolchains are often not required. Briefly, then, for an end user, in order of use:

Classic Intel Compilers (commercial)

These are maintained actively, though licensing restrictions may apply as further detailed in *F2PY and Windows Intel Fortran*.

Suitable for general use for those building native Windows programs by building off of MSVC.

MSYS2 (FOSS)

In conjunction with the `mingw-w64` project, `gfortran` and `gcc` toolchains can be used to natively build Windows programs.

Windows Subsystem for Linux

Assuming the usage of `gfortran`, this can be used for cross-compiling Windows applications, but is significantly more complicated.

Conda

Windows support for GNU compilers in `conda` is provided by `conda-forge` channel.

PGI Compilers (commercial)

Unmaintained but sufficient if an existing license is present. Works natively, but has been superseded by the Nvidia HPC SDK, with no `native Windows support`.

Cygwin (FOSS)

Can also be used for `gfortran`. However, the POSIX API compatibility layer provided by Cygwin is meant to compile UNIX software on Windows, instead of building native Windows programs. This means cross compilation is required.

Intel oneAPI

The newer Intel compilers (`ifx`, `icx`) are based on LLVM and can be used for native compilation. Licensing requirements can be onerous.

Classic Flang (FOSS)

The backbone of the PGI compilers were cannibalized to form the “classic” or `legacy version of Flang`. This may be compiled from source and used natively. `LLVM Flang` does not support Windows yet (30-01-2022).

LFortran (FOSS)

One of two LLVM based compilers. Not all of F2PY supported Fortran can be compiled yet (30-01-2022) but uses MSVC for native linking.

Baseline

For this document we will assume the following basic tools:

- The IDE being considered is the community supported [Microsoft Visual Studio Code](#)
- The terminal being used is the [Windows Terminal](#)
- The shell environment is assumed to be [Powershell 7.x](#)
- **Python 3.10 from the [Microsoft Store](#) and this can be tested with**
`Get-Command python.exe` resolving to `C:\Users\%USERNAME\AppData\Local\Microsoft\WindowsApps\python.exe`
- The Microsoft Visual C++ (MSVC) toolset

With this baseline configuration, we will further consider a configuration matrix as follows:

Table 5: Support matrix, exe implies a Windows installer

Fortran Compiler	C/C++ Compiler	Source
Intel Fortran	MSVC / ICC	exe
GFortran	MSVC	MSYS2/exe
GFortran	GCC	WSL
Classic Flang	MSVC	Source / Conda
Anaconda GFortran	Anaconda GCC	exe

For an understanding of the key issues motivating the need for such a matrix [Pauli Virtanen's in-depth post on wheels with Fortran for Windows](#) is an excellent resource. An entertaining explanation of an application binary interface (ABI) can be found in this post by [JeanHeyd Meneide](#).

PowerShell and MSVC

MSVC is installed either via the Visual Studio Bundle or the lighter (preferred) [Build Tools for Visual Studio](#) with the Desktop development with C++ setting.

Note: This can take a significant amount of time as it includes a download of around 2GB and requires a restart.

It is possible to use the resulting environment from a [standard command prompt](#). However, it is more pleasant to use a [developer powershell](#), with a [profile in Windows Terminal](#). This can be achieved by adding the following block to the `profiles->list` section of the JSON file used to configure Windows Terminal (see `Settings->Open JSON file`):

```
{
  "name": "Developer PowerShell for VS 2019",
  "commandline": "powershell.exe -noe -c \"%$vsPath = (Join-Path ${env:ProgramFiles(x86)} `
  ↪ -ChildPath 'Microsoft Visual Studio\\2019\\BuildTools'); Import-Module (Join-Path `
  ↪ $vsPath 'Common7\\Tools\\Microsoft.VisualStudio.DevShell.dll'); Enter-VsDevShell - `
  ↪ VsInstallPath $vsPath -SkipAutomaticLocation\"",
  "icon": "ms-appx:///ProfileIcons/{61c54bbd-c2c6-5271-96e7-009a87ff44bf}.png"
}
```

Now, testing the compiler toolchain could look like:

```
# New Windows Developer Powershell instance / tab
# or
$vsPath = (Join-Path ${env:ProgramFiles(x86)} -ChildPath 'Microsoft Visual Studio\
↪2019\BuildTools');
Import-Module (Join-Path $vsPath 'Common7\Tools\Microsoft.VisualStudio.DevShell.dll
↪');
Enter-VsDevShell -VsInstallPath $vsPath -SkipAutomaticLocation
*****
** Visual Studio 2019 Developer PowerShell v16.11.9
** Copyright (c) 2021 Microsoft Corporation
*****
cd $HOME
echo "#include<stdio.h>" > blah.cpp; echo 'int main(){printf("Hi");return 1;}' >>_
↪blah.cpp
cl blah.cpp
.\blah.exe
# Hi
rm blah.cpp
```

It is also possible to check that the environment has been updated correctly with `$ENV:PATH`.

Microsoft Store Python paths

The MS Windows version of Python discussed here installs to a non-deterministic path using a hash. This needs to be added to the `PATH` variable.

```
$Env:Path += ";$env:LOCALAPPDATA\packages\pythonsoftwarefoundation.python.3.10_
↪qbz5n2kfra8p0\localcache\local-packages\python310\scripts"
```

F2PY and Windows Intel Fortran

As of NumPy 1.23, only the classic Intel compilers (`ifort`) are supported.

Note: The licensing restrictions for beta software [have been relaxed](#) during the transition to the LLVM backed `ifx/icc` family of compilers. However this document does not endorse the usage of Intel in downstream projects due to the issues pertaining to [disassembly of components and liability](#).

Neither the Python Intel installation nor the *Classic Intel C/C++ Compiler* are required.

- The [Intel Fortran Compilers](#) come in a combined installer providing both Classic and Beta versions; these also take around a gigabyte and a half or so.

We will consider the classic example of the generation of Fibonacci numbers, `fib1.f`, given by:

```
C FILE: FIB1.F
      SUBROUTINE FIB(A,N)
C
C      CALCULATE FIRST N FIBONACCI NUMBERS
C
      INTEGER N
      REAL*8 A(N)
      DO I=1,N
        IF (I.EQ.1) THEN
```

(continues on next page)

(continued from previous page)

```

        A(I) = 0.0D0
    ELSEIF (I.EQ.2) THEN
        A(I) = 1.0D0
    ELSE
        A(I) = A(I-1) + A(I-2)
    ENDIF
ENDDO
END
C END FILE FIB1.F

```

For `cmd.exe` fans, using the Intel oneAPI command prompt is the easiest approach, as it loads the required environment for both `ifort` and `msvc`. Helper batch scripts are also provided.

```

# cmd.exe
"C:\Program Files (x86)\Intel\oneAPI\setvars.bat"
python -m numpy.f2py -c fib1.f -m fib1
python -c "import fib1; import numpy as np; a=np.zeros(8); fib1.fib(a); print(a)"

```

Powershell usage is a little less pleasant, and this configuration now works with MSVC as:

```

# Powershell
python -m numpy.f2py -c fib1.f -m fib1 --f77exec='C:\Program Files (x86)\Intel\oneAPI\
↪ compiler\latest\windows\bin\intel64\ifort.exe' --f90exec='C:\Program Files (x86)\
↪ Intel\oneAPI\compiler\latest\windows\bin\intel64\ifort.exe' -L'C:\Program Files.
↪ (x86)\Intel\oneAPI\compiler\latest\windows\compiler\lib\ia32'
python -c "import fib1; import numpy as np; a=np.zeros(8); fib1.fib(a); print(a)"
# Alternatively, set environment and reload Powershell in one line
cmd.exe /k "C:\Program Files (x86)\Intel\oneAPI\setvars.bat" && powershell'
python -m numpy.f2py -c fib1.f -m fib1
python -c "import fib1; import numpy as np; a=np.zeros(8); fib1.fib(a); print(a)"

```

Note that the actual path to your local installation of *ifort* may vary, and the command above will need to be updated accordingly.

F2PY and Windows with MSYS2

Follow the standard [installation instructions](#). Then, to grab the requisite Fortran compiler with MVSC:

```

# Assuming a fresh install
pacman -Syu # Restart the terminal
pacman -Su # Update packages
# Get the toolchains
pacman -S --needed base-devel gcc-fortran
pacman -S mingw-w64-x86_64-toolchain

```

F2PY and Conda on Windows

As a convenience measure, we will additionally assume the existence of `scoop`, which can be used to install tools without administrative access.

```
Invoke-Expression (New-Object System.Net.WebClient).DownloadString('https://get.scoop.  
↪sh')
```

Now we will setup a conda environment.

```
scoop install miniconda3  
# For conda activate / deactivate in powershell  
conda install -n root -c pscondaenvs pscondaenvs  
Powershell -c Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope CurrentUser  
conda init powershell  
# Open a new shell for the rest
```

conda pulls packages from `msys2`, however, the UX is sufficiently different enough to warrant a separate discussion.

F2PY and PGI Fortran on Windows

A variant of these are part of the so called “classic” Flang, however, as classic Flang requires a custom LLVM and compilation from sources.

Warning: Since the proprietary compilers are no longer available for usage they are not recommended and will not be ported to the new `f2py` CLI.

Note: As of November 2021

As of 29-01-2022, `PGI compiler toolchains` have been superseded by the Nvidia HPC SDK, with no `native Windows` support.

Masked array operations

Constants

<code>ma.MaskType</code>	alias of <code>bool</code>
--------------------------	----------------------------

`numpy.ma.MaskType`

alias of `bool`

Creation

From existing data

<code>ma.masked_array</code>	alias of <code>MaskedArray</code>
<code>ma.array(data[, dtype, copy, order, mask, ...])</code>	An array class with possibly masked values.
<code>ma.copy(a.copy)</code>	Return a copy of the array.
<code>ma.frombuffer(buffer[, dtype, count, ...])</code>	Interpret a buffer as a 1-dimensional array.
<code>ma.fromfunction(function, shape, *[dtype, ...])</code>	Construct an array by executing a function over each co-ordinate.
<code>ma.MaskedArray.copy([order])</code>	Return a copy of the array.
<code>ma.diagflat(v[, k])</code>	Create a two-dimensional array with the flattened input as a diagonal.

`numpy.ma.masked_array`

alias of `MaskedArray`

`ma.array` (*data*, *dtype=None*, *copy=False*, *order=None*, *mask=np.False_*, *fill_value=None*, *keep_mask=True*, *hard_mask=False*, *shrink=True*, *subok=True*, *ndmin=0*)

An array class with possibly masked values.

Masked values of True exclude the corresponding element from any computation.

Construction:

```
x = MaskedArray(data, mask=nomask, dtype=None, copy=False, subok=True,
                 ndmin=0, fill_value=None, keep_mask=True, hard_mask=None,
                 shrink=True, order=None)
```

Parameters

data

[array_like] Input data.

mask

[sequence, optional] Mask. Must be convertible to an array of booleans with the same shape as *data*. True indicates a masked (i.e. invalid) data.

dtype

[dtype, optional] Data type of the output. If *dtype* is None, the type of the data argument (*data.dtype*) is used. If *dtype* is not None and different from *data.dtype*, a copy is performed.

copy

[bool, optional] Whether to copy the input data (True), or to use a reference instead. Default is False.

subok

[bool, optional] Whether to return a subclass of `MaskedArray` if possible (True) or a plain `MaskedArray`. Default is True.

ndmin

[int, optional] Minimum number of dimensions. Default is 0.

fill_value

[scalar, optional] Value used to fill in the masked values when necessary. If None, a default based on the data-type is used.

keep_mask

[bool, optional] Whether to combine *mask* with the mask of the input data, if any (True), or to use only *mask* for the output (False). Default is True.

hard_mask

[bool, optional] Whether to use a hard mask or not. With a hard mask, masked values cannot be unmasked. Default is False.

shrink

[bool, optional] Whether to force compression of an empty mask. Default is True.

order

[{'C', 'F', 'A'}, optional] Specify the order of the array. If order is 'C', then the array will be in C-contiguous order (last-index varies the fastest). If order is 'F', then the returned array will be in Fortran-contiguous order (first-index varies the fastest). If order is 'A' (default), then the returned array may be in any order (either C-, Fortran-contiguous, or even discontinuous), unless a copy is required, in which case it will be C-contiguous.

Examples

```
>>> import numpy as np
```

The mask can be initialized with an array of boolean values with the same shape as `data`.

```
>>> data = np.arange(6).reshape((2, 3))
>>> np.ma.MaskedArray(data, mask=[[False, True, False],
...                               [False, False, True]])
masked_array(
  data=[[0, --, 2],
        [3, 4, --]],
  mask=[[False,  True, False],
        [False, False,  True]],
  fill_value=999999)
```

Alternatively, the mask can be initialized to homogeneous boolean array with the same shape as `data` by passing in a scalar boolean value:

```
>>> np.ma.MaskedArray(data, mask=False)
masked_array(
  data=[[0, 1, 2],
        [3, 4, 5]],
  mask=[[False, False, False],
        [False, False, False]],
  fill_value=999999)
```

```
>>> np.ma.MaskedArray(data, mask=True)
masked_array(
  data=[[--, --, --],
        [--, --, --]],
  mask=[[ True,  True,  True],
        [ True,  True,  True]],
  fill_value=999999,
  dtype=int64)
```

Note: The recommended practice for initializing mask with a scalar boolean value is to use `True/False` rather than `np.True_/np.False_`. The reason is *nomask* is represented internally as `np.False_`.

```
>>> np.False_ is np.ma.nomask
True
```

`ma.copy(self, *args, **params) a.copy(order='C')`

`ma.copy(order='C') → None`

Return a copy of the array.

Parameters

order

[['C', 'F', 'A', 'K'], optional] Controls the memory layout of the copy. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *a* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *a* as closely as possible. (Note that this function and [numpy.copy](#) are very similar but have different default values for their `order=` arguments, and this function always passes sub-classes through.)

See also:

[numpy.copy](#)

Similar function with different default behavior

[numpy.copyto](#)

Notes

This function is the preferred method for creating an array copy. The function [numpy.copy](#) is similar, but it defaults to using order 'K', and will not pass sub-classes through by default.

Examples

```
>>> import numpy as np
>>> x = np.array([[1,2,3],[4,5,6]], order='F')
```

```
>>> y = x.copy()
```

```
>>> x.fill(0)
```

```
>>> x
array([[0, 0, 0],
       [0, 0, 0]])
```

```
>>> y
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> y.flags['C_CONTIGUOUS']
True
```

For arrays containing Python objects (e.g. `dtype=np.object_`), the copy is a shallow one. The new array will contain the same object which may lead to surprises if that object can be modified (is mutable):

```
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> b = a.copy()
>>> b[2][0] = 10
>>> a
array([1, 'm', list([10, 3, 4])], dtype=object)
```

To ensure all elements within an object array are copied, use `copy.deepcopy`:

```
>>> import copy
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> c = copy.deepcopy(a)
>>> c[2][0] = 10
>>> c
array([1, 'm', list([10, 3, 4])], dtype=object)
>>> a
array([1, 'm', list([2, 3, 4])], dtype=object)
```

`ma.frombuffer` (*buffer*, *dtype=np.float64*, *count=-1*, *offset=0*, *, *like=None*)

Interpret a buffer as a 1-dimensional array.

Parameters

buffer

[*buffer_like*] An object that exposes the buffer interface.

dtype

[*data-type*, optional] Data-type of the returned array. Default is `numpy.float64`.

count

[*int*, optional] Number of items to read. -1 means all data in the buffer.

offset

[*int*, optional] Start reading the buffer from this offset (in bytes); default: 0.

like

[*array_like*, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out: `MaskedArray`

See also:

[`ndarray.tobytes`](#)

Inverse of this operation, construct Python bytes from the raw data bytes in the array.

Notes

If the buffer has data that is not in machine byte-order, this should be specified as part of the data-type, e.g.:

```
>>> dt = np.dtype(np.int_)
>>> dt = dt.newbyteorder('>')
>>> np.frombuffer(buf, dtype=dt)
```

The data of the resulting array will not be byteswapped, but will be interpreted correctly.

This function creates a view into the original object. This should be safe in general, but it may make sense to copy the result when the original object is mutable or untrusted.

Examples

```
>>> import numpy as np
>>> s = b'hello world'
>>> np.frombuffer(s, dtype='S1', count=5, offset=6)
array([b'w', b'o', b'r', b'l', b'd'], dtype='|S1')
```

```
>>> np.frombuffer(b'\x01\x02', dtype=np.uint8)
array([1, 2], dtype=uint8)
>>> np.frombuffer(b'\x01\x02\x03\x04\x05', dtype=np.uint8, count=3)
array([1, 2, 3], dtype=uint8)
```

ma.**fromfunction** (*function*, *shape*, *, *dtype*=<class 'float'>, *like*=None, ***kwargs*)

Construct an array by executing a function over each coordinate.

The resulting array therefore has a value $fn(x, y, z)$ at coordinate (x, y, z) .

Parameters

function

[callable] The function is called with N parameters, where N is the rank of *shape*. Each parameter represents the coordinates of the array varying along a specific axis. For example, if *shape* were $(2, 2)$, then the parameters would be `array([[0, 0], [1, 1]])` and `array([[0, 1], [0, 1]])`

shape

$(N,)$ tuple of ints] Shape of the output array, which also determines the shape of the coordinate arrays passed to *function*.

dtype

[data-type, optional] Data-type of the coordinate arrays passed to *function*. By default, *dtype* is float.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

fromfunction: MaskedArray

The result of the call to *function* is passed back directly. Therefore the shape of *fromfunction* is completely determined by *function*. If *function* returns a scalar value, the shape of *fromfunction* would not match the *shape* parameter.

See also:

[*indices, meshgrid*](#)

Notes

Keywords other than *dtype* and *like* are passed to *function*.

Examples

```
>>> import numpy as np
>>> np.fromfunction(lambda i, j: i, (2, 2), dtype=np.float64)
array([[0., 0.],
       [1., 1.]])
```

```
>>> np.fromfunction(lambda i, j: j, (2, 2), dtype=np.float64)
array([[0., 1.],
       [0., 1.]])
```

```
>>> np.fromfunction(lambda i, j: i == j, (3, 3), dtype=np.int_)
array([[ True, False, False],
       [False,  True, False],
       [False, False,  True]])
```

```
>>> np.fromfunction(lambda i, j: i + j, (3, 3), dtype=np.int_)
array([[0, 1, 2],
       [1, 2, 3],
       [2, 3, 4]])
```

method

`ma.MaskedArray.copy (order='C')`

Return a copy of the array.

Parameters**order**

[[‘C’, ‘F’, ‘A’, ‘K’], optional] Controls the memory layout of the copy. ‘C’ means C-order, ‘F’ means F-order, ‘A’ means ‘F’ if *a* is Fortran contiguous, ‘C’ otherwise. ‘K’ means match the layout of *a* as closely as possible. (Note that this function and [*numpy.copy*](#) are very similar but have different default values for their *order=* arguments, and this function always passes sub-classes through.)

See also:

[*numpy.copy*](#)

Similar function with different default behavior

[*numpy.copyto*](#)

Notes

This function is the preferred method for creating an array copy. The function `numpy.copy` is similar, but it defaults to using order 'K', and will not pass sub-classes through by default.

Examples

```
>>> import numpy as np
>>> x = np.array([[1,2,3],[4,5,6]], order='F')
```

```
>>> y = x.copy()
```

```
>>> x.fill(0)
```

```
>>> x
array([[0, 0, 0],
       [0, 0, 0]])
```

```
>>> y
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> y.flags['C_CONTIGUOUS']
True
```

For arrays containing Python objects (e.g. `dtype=np.object_`), the copy is a shallow one. The new array will contain the same object which may lead to surprises if that object can be modified (is mutable):

```
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> b = a.copy()
>>> b[2][0] = 10
>>> a
array([1, 'm', list([10, 3, 4])], dtype=object)
```

To ensure all elements within an object array are copied, use `copy.deepcopy`:

```
>>> import copy
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> c = copy.deepcopy(a)
>>> c[2][0] = 10
>>> c
array([1, 'm', list([10, 3, 4])], dtype=object)
>>> a
array([1, 'm', list([2, 3, 4])], dtype=object)
```

`ma.diagflat` (*v*, *k*=0)

Create a two-dimensional array with the flattened input as a diagonal.

Parameters

v

[array_like] Input data, which is flattened and set as the *k*-th diagonal of the output.

k

[int, optional] Diagonal to set; 0, the default, corresponds to the “main” diagonal, a positive (negative) *k* giving the number of the diagonal above (below) the main.

Returns**out**

[ndarray] The 2-D output array.

See also:*diag*

MATLAB work-alike for 1-D and 2-D arrays.

diagonal

Return specified diagonals.

trace

Sum along diagonals.

NotesThe function is applied to both the `_data` and the `_mask`, if any.**Examples**

```
>>> import numpy as np
>>> np.diagflat([[1,2], [3,4]])
array([[1, 0, 0, 0],
       [0, 2, 0, 0],
       [0, 0, 3, 0],
       [0, 0, 0, 4]])
```

```
>>> np.diagflat([1,2], 1)
array([[0, 1, 0],
       [0, 0, 2],
       [0, 0, 0]])
```

Ones and zeros

<code>ma.empty(shape[, dtype, order, device, like])</code>	Return a new array of given shape and type, without initializing entries.
<code>ma.empty_like(prototype, /[, dtype, order, ...])</code>	Return a new array with the same shape and type as a given array.
<code>ma.masked_all(shape[, dtype])</code>	Empty masked array with all elements masked.
<code>ma.masked_all_like(arr)</code>	Empty masked array with the properties of an existing array.
<code>ma.ones(shape[, dtype, order, device, like, ...])</code>	Return a new array of given shape and type, filled with ones.
<code>ma.ones_like(a[, dtype, order, subok, ...])</code>	Return an array of ones with the same shape and type as a given array.
<code>ma.zeros(shape[, dtype, order, device, like])</code>	Return a new array of given shape and type, filled with zeros.
<code>ma.zeros_like(a[, dtype, order, subok, ...])</code>	Return an array of zeros with the same shape and type as a given array.

`ma.empty(shape, dtype=None, order='C', *, device=None, like=None)`

Return a new array of given shape and type, without initializing entries.

Parameters

shape

[int or tuple of int] Shape of the empty array, e.g., (2, 3) or 2.

dtype

[data-type, optional] Desired output data-type for the array, e.g. `numpy.int8`. Default is `numpy.float64`.

order

[{'C', 'F'}, optional, default: 'C'] Whether to store multi-dimensional data in row-major (C-style) or column-major (Fortran-style) order in memory.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[MaskedArray] Array of uninitialized (arbitrary) data of the given shape, dtype, and order. Object arrays will be initialized to None.

See also:

`empty_like`

Return an empty array with shape and type of input.

`ones`

Return a new array setting values to one.

`zeros`

Return a new array setting values to zero.

`full`

Return a new array of given shape filled with value.

Notes

Unlike other array creation functions (e.g. `zeros`, `ones`, `full`), `empty` does not initialize the values of the array, and may therefore be marginally faster. However, the values stored in the newly allocated array are arbitrary. For reproducible behavior, be sure to set each element of the array before reading.

Examples

```
>>> import numpy as np
>>> np.empty([2, 2])
array([[ -9.74499359e+001,   6.69583040e-309],
       [  2.13182611e-314,   3.06959433e-309]])      #uninitialized
```

```
>>> np.empty([2, 2], dtype=np.int_)
array([[ -1073741821, -1067949133],
       [  496041986,   19249760]])      #uninitialized
```

`ma.empty_like` (*prototype*, /, *dtype=None*, *order='K'*, *subok=True*, *shape=None*, *, *device=None*)

Return a new array with the same shape and type as a given array.

Parameters

prototype

[array_like] The shape and data-type of *prototype* define these same attributes of the returned array.

dtype

[data-type, optional] Overrides the data type of the result.

order

['C', 'F', 'A', or 'K'], optional] Overrides the memory layout of the result. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *prototype* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *prototype* as closely as possible.

subok

[bool, optional.] If True, then the newly created array will use the sub-class type of *prototype*, otherwise it will be a base-class array. Defaults to True.

shape

[int or sequence of ints, optional.] Overrides the shape of the result. If order='K' and the number of dimensions is unchanged, will try to keep order, otherwise, order='C' is implied.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

Returns

out

[MaskedArray] Array of uninitialized (arbitrary) data with the same shape and type as *prototype*.

See also:

ones_like

Return an array of ones with shape and type of input.

zeros_like

Return an array of zeros with shape and type of input.

full_like

Return a new array with shape of input filled with value.

empty

Return a new uninitialized array.

Notes

Unlike other array creation functions (e.g. `zeros_like`, `ones_like`, `full_like`), `empty_like` does not initialize the values of the array, and may therefore be marginally faster. However, the values stored in the newly allocated array are arbitrary. For reproducible behavior, be sure to set each element of the array before reading.

Examples

```
>>> import numpy as np
>>> a = ([1,2,3], [4,5,6])           # a is array-like
>>> np.empty_like(a)
array([[ -1073741821, -1073741821,          3],      # uninitialized
       [          0,          0, -1073741821]])
>>> a = np.array([[1., 2., 3.], [4.,5.,6.]])
>>> np.empty_like(a)
array([[ -2.00000715e+000,  1.48219694e-323, -2.00000572e+000], # uninitialized
       [  4.38791518e-305, -2.00000715e+000,  4.17269252e-309]])
```

`ma.masked_all` (*shape*, *dtype*=<class 'float'>)

Empty masked array with all elements masked.

Return an empty masked array of the given shape and dtype, where all the data are masked.

Parameters

shape

[int or tuple of ints] Shape of the required MaskedArray, e.g., (2, 3) or 2.

dtype

[dtype, optional] Data type of the output.

Returns

a

[MaskedArray] A masked array with all data masked.

See also:

`masked_all_like`

Empty masked array modelled on an existing array.

Notes

Unlike other masked array creation functions (e.g. `numpy.ma.zeros`, `numpy.ma.ones`, `numpy.ma.full`), `masked_all` does not initialize the values of the array, and may therefore be marginally faster. However, the values stored in the newly allocated array are arbitrary. For reproducible behavior, be sure to set each element of the array before reading.

Examples

```
>>> import numpy as np
>>> np.ma.masked_all((3, 3))
masked_array(
  data=[[--, --, --],
        [--, --, --],
        [--, --, --]],
  mask=[[ True,  True,  True],
        [ True,  True,  True],
        [ True,  True,  True]],
  fill_value=1e+20,
  dtype=float64)
```

The `dtype` parameter defines the underlying data type.

```
>>> a = np.ma.masked_all((3, 3))
>>> a.dtype
dtype('float64')
>>> a = np.ma.masked_all((3, 3), dtype=np.int32)
>>> a.dtype
dtype('int32')
```

`ma.masked_all_like(arr)`

Empty masked array with the properties of an existing array.

Return an empty masked array of the same shape and dtype as the array *arr*, where all the data are masked.

Parameters

arr

[ndarray] An array describing the shape and dtype of the required MaskedArray.

Returns

a

[MaskedArray] A masked array with all data masked.

Raises

AttributeError

If *arr* doesn't have a shape attribute (i.e. not an ndarray)

See also:

[`masked\_all`](#)

Empty masked array with all elements masked.

Notes

Unlike other masked array creation functions (e.g. `numpy.ma.zeros_like`, `numpy.ma.ones_like`, `numpy.ma.full_like`), `masked_all_like` does not initialize the values of the array, and may therefore be marginally faster. However, the values stored in the newly allocated array are arbitrary. For reproducible behavior, be sure to set each element of the array before reading.

Examples

```
>>> import numpy as np
>>> arr = np.zeros((2, 3), dtype=np.float32)
>>> arr
array([[0., 0., 0.],
       [0., 0., 0.]], dtype=float32)
>>> np.ma.masked_all_like(arr)
masked_array(
  data=[--, --, --],
  [--, --, --]],
  mask=[ True,  True,  True],
        [ True,  True,  True]],
  fill_value=np.float64(1e+20),
  dtype=float32)
```

The dtype of the masked array matches the dtype of *arr*.

```
>>> arr.dtype
dtype('float32')
>>> np.ma.masked_all_like(arr).dtype
dtype('float32')
```

`ma.ones` (*shape*, *dtype=None*, *order='C'*, *, *device=None*, *like=None*, *fill_value=None*, *hardmask=False*)

Return a new array of given shape and type, filled with ones.

Parameters

shape

[int or sequence of ints] Shape of the new array, e.g., (2, 3) or 2.

dtype

[data-type, optional] The desired data-type for the array, e.g., `numpy.int8`. Default is `numpy.float64`.

order

[{'C', 'F'}, optional, default: C] Whether to store multi-dimensional data in row-major (C-style) or column-major (Fortran-style) order in memory.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[MaskedArray] Array of ones with the given shape, dtype, and order.

See also:

ones_like

Return an array of ones with shape and type of input.

empty

Return a new uninitialized array.

zeros

Return a new array setting values to zero.

full

Return a new array of given shape filled with value.

Examples

```
>>> import numpy as np
>>> np.ones(5)
array([1., 1., 1., 1., 1.])
```

```
>>> np.ones((5,), dtype=np.int_)
array([1, 1, 1, 1, 1])
```

```
>>> np.ones((2, 1))
array([[1.],
       [1.]])
```

```
>>> s = (2, 2)
>>> np.ones(s)
array([[1., 1.],
       [1., 1.]])
```

`ma.ones_like(a, dtype=None, order='K', subok=True, shape=None, *, device=None)`

Return an array of ones with the same shape and type as a given array.

Parameters**a**

[array_like] The shape and data-type of *a* define these same attributes of the returned array.

dtype

[data-type, optional] Overrides the data type of the result.

order

['C', 'F', 'A', or 'K'], optional] Overrides the memory layout of the result. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *a* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *a* as closely as possible.

subok

[bool, optional.] If True, then the newly created array will use the sub-class type of *a*, otherwise it will be a base-class array. Defaults to True.

shape

[int or sequence of ints, optional.] Overrides the shape of the result. If order='K' and the number of dimensions is unchanged, will try to keep order, otherwise, order='C' is implied.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

Returns

out

[MaskedArray] Array of ones with the same shape and type as *a*.

See also:

empty_like

Return an empty array with shape and type of input.

zeros_like

Return an array of zeros with shape and type of input.

full_like

Return a new array with shape of input filled with value.

ones

Return a new array setting values to one.

Examples

```
>>> import numpy as np
>>> x = np.arange(6)
>>> x = x.reshape((2, 3))
>>> x
array([[0, 1, 2],
       [3, 4, 5]])
>>> np.ones_like(x)
array([[1, 1, 1],
       [1, 1, 1]])
```

```
>>> y = np.arange(3, dtype=np.float64)
>>> y
array([0., 1., 2.])
>>> np.ones_like(y)
array([1., 1., 1.])
```

ma.zeros (*shape*, *dtype=None*, *order='C'*, ***, *device=None*, *like=None*)

Return a new array of given shape and type, filled with zeros.

Parameters

shape

[int or tuple of ints] Shape of the new array, e.g., (2, 3) or 2.

dtype

[data-type, optional] The desired data-type for the array, e.g., `numpy.int8`. Default is `numpy.float64`.

order

[{'C', 'F'}, optional, default: 'C'] Whether to store multi-dimensional data in row-major (C-style) or column-major (Fortran-style) order in memory.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns**out**

[MaskedArray] Array of zeros with the given shape, dtype, and order.

See also:**`zeros_like`**

Return an array of zeros with shape and type of input.

`empty`

Return a new uninitialized array.

`ones`

Return a new array setting values to one.

`full`

Return a new array of given shape filled with value.

Examples

```
>>> import numpy as np
>>> np.zeros(5)
array([ 0.,  0.,  0.,  0.,  0.]
```

```
>>> np.zeros((5,), dtype=np.int_)
array([0, 0, 0, 0, 0])
```

```
>>> np.zeros((2, 1))
array([[ 0.],
       [ 0.]])
```

```
>>> s = (2,2)
>>> np.zeros(s)
array([[ 0.,  0.],
       [ 0.,  0.]])
```

```
>>> np.zeros((2,), dtype=[('x', 'i4'), ('y', 'i4')]) # custom dtype
array([(0, 0), (0, 0)],
      dtype=[('x', '<i4'), ('y', '<i4')])
```

`ma.zeros_like(a, dtype=None, order='K', subok=True, shape=None, *, device=None)`

Return an array of zeros with the same shape and type as a given array.

Parameters**a**

[array_like] The shape and data-type of *a* define these same attributes of the returned array.

dtype

[data-type, optional] Overrides the data type of the result.

order

[{'C', 'F', 'A', or 'K'}, optional] Overrides the memory layout of the result. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *a* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *a* as closely as possible.

subok

[bool, optional.] If True, then the newly created array will use the sub-class type of *a*, otherwise it will be a base-class array. Defaults to True.

shape

[int or sequence of ints, optional.] Overrides the shape of the result. If order='K' and the number of dimensions is unchanged, will try to keep order, otherwise, order='C' is implied.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

Returns**out**

[MaskedArray] Array of zeros with the same shape and type as *a*.

See also:***empty_like***

Return an empty array with shape and type of input.

ones_like

Return an array of ones with shape and type of input.

full_like

Return a new array with shape of input filled with value.

zeros

Return a new array setting values to zero.

Examples

```
>>> import numpy as np
>>> x = np.arange(6)
>>> x = x.reshape((2, 3))
>>> x
array([[0, 1, 2],
       [3, 4, 5]])
>>> np.zeros_like(x)
array([[0, 0, 0],
       [0, 0, 0]])
```

```
>>> y = np.arange(3, dtype=np.float64)
>>> y
array([0., 1., 2.])
>>> np.zeros_like(y)
array([0., 0., 0.])
```

Inspecting the array

<code>ma.all(self[, axis, out, keepdims])</code>	Returns True if all elements evaluate to True.
<code>ma.any(self[, axis, out, keepdims])</code>	Returns True if any of the elements of <i>a</i> evaluate to True.
<code>ma.count(self[, axis, keepdims])</code>	Count the non-masked elements of the array along the given axis.
<code>ma.count_masked(arr[, axis])</code>	Count the number of masked elements along the given axis.
<code>ma.getmask(a)</code>	Return the mask of a masked array, or nomask.
<code>ma.getmaskarray(arr)</code>	Return the mask of a masked array, or full boolean array of False.
<code>ma.getdata(a[, subok])</code>	Return the data of a masked array as an ndarray.
<code>ma.nonzero(self)</code>	Return the indices of unmasked elements that are not zero.
<code>ma.shape(obj)</code>	Return the shape of an array.
<code>ma.size(obj[, axis])</code>	Return the number of elements along a given axis.
<code>ma.is_masked(x)</code>	Determine whether input has masked values.
<code>ma.is_mask(m)</code>	Return True if <i>m</i> is a valid, standard mask.
<code>ma.isMaskedArray(x)</code>	Test whether input is an instance of MaskedArray.
<code>ma.isMA(x)</code>	Test whether input is an instance of MaskedArray.
<code>ma.isarray(x)</code>	Test whether input is an instance of MaskedArray.
<code>ma.isin(element, test_elements[, ...])</code>	Calculates <i>element in test_elements</i> , broadcasting over <i>element</i> only.
<code>ma.in1d(ar1, ar2[, assume_unique, invert])</code>	Test whether each element of an array is also present in a second array.
<code>ma.unique(ar1[, return_index, return_inverse])</code>	Finds the unique elements of an array.
<code>ma.MaskedArray.all([axis, out, keepdims])</code>	Returns True if all elements evaluate to True.
<code>ma.MaskedArray.any([axis, out, keepdims])</code>	Returns True if any of the elements of <i>a</i> evaluate to True.
<code>ma.MaskedArray.count([axis, keepdims])</code>	Count the non-masked elements of the array along the given axis.
<code>ma.MaskedArray.nonzero()</code>	Return the indices of unmasked elements that are not zero.
<code>ma.shape(obj)</code>	Return the shape of an array.
<code>ma.size(obj[, axis])</code>	Return the number of elements along a given axis.

`ma.all(self, axis=None, out=None, keepdims=<no value>)`

Returns True if all elements evaluate to True.

The output array is masked where all the values along the given axis are masked: if the output would have been a scalar and that all the values are masked, then the output is *masked*.

Refer to [numpy.all](#) for full documentation.

See also:

[numpy.ndarray.all](#)

corresponding function for ndarrays

[numpy.all](#)

equivalent function

Examples

```
>>> import numpy as np
>>> np.ma.array([1,2,3]).all()
True
>>> a = np.ma.array([1,2,3], mask=True)
>>> (a.all() is np.ma.masked)
True
```

ma.any (*self*, *axis=None*, *out=None*, *keepdims=<no value>*)

Returns True if any of the elements of *a* evaluate to True.

Masked values are considered as False during computation.

Refer to [numpy.any](#) for full documentation.

See also:

[numpy.ndarray.any](#)

corresponding function for ndarrays

[numpy.any](#)

equivalent function

ma.count (*self*, *axis=None*, *keepdims=<no value>*)

Count the non-masked elements of the array along the given axis.

Parameters

axis

[None or int or tuple of ints, optional] Axis or axes along which the count is performed. The default, None, performs the count over all the dimensions of the input array. *axis* may be negative, in which case it counts from the last to the first axis. If this is a tuple of ints, the count is performed on multiple axes, instead of a single axis or all the axes as before.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the array.

Returns

result

[ndarray or scalar] An array with the same shape as the input array, with the specified axis removed. If the array is a 0-d array, or if *axis* is None, a scalar is returned.

See also:

[ma.count_masked](#)

Count masked elements in array or along a given axis.

Examples

```
>>> import numpy.ma as ma
>>> a = ma.arange(6).reshape((2, 3))
>>> a[1, :] = ma.masked
>>> a
masked_array(
  data=[[0, 1, 2],
        [--, --, --]],
  mask=[[False, False, False],
        [ True,  True,  True]],
  fill_value=999999)
>>> a.count()
3
```

When the *axis* keyword is specified an array of appropriate size is returned.

```
>>> a.count(axis=0)
array([1, 1, 1])
>>> a.count(axis=1)
array([3, 0])
```

`ma.count_masked(arr, axis=None)`

Count the number of masked elements along the given axis.

Parameters

arr

[array_like] An array with (possibly) masked elements.

axis

[int, optional] Axis along which to count. If None (default), a flattened version of the array is used.

Returns

count

[int, ndarray] The total number of masked elements (*axis=None*) or the number of masked elements along each slice of the given axis.

See also:

MaskedArray.count

Count non-masked elements.

Examples

```
>>> import numpy as np
>>> a = np.arange(9).reshape((3, 3))
>>> a = np.ma.array(a)
>>> a[1, 0] = np.ma.masked
>>> a[1, 2] = np.ma.masked
>>> a[2, 1] = np.ma.masked
>>> a
masked_array(
  data=[[0, 1, 2],
        [--, 4, --]],
```

(continues on next page)

(continued from previous page)

```

        [6, --, 8]],
    mask=[[False, False, False],
          [ True, False,  True],
          [False,  True, False]],
    fill_value=999999)
>>> np.ma.count_masked(a)
3

```

When the *axis* keyword is used an array is returned.

```

>>> np.ma.count_masked(a, axis=0)
array([1, 1, 1])
>>> np.ma.count_masked(a, axis=1)
array([0, 2, 1])

```

ma.getmask(a)

Return the mask of a masked array, or *nomask*.

Return the mask of *a* as an ndarray if *a* is a *MaskedArray* and the mask is not *nomask*, else return *nomask*. To guarantee a full array of booleans of the same shape as *a*, use *getmaskarray*.

Parameters

a

[array_like] Input *MaskedArray* for which the mask is required.

See also:

getdata

Return the data of a masked array as an ndarray.

getmaskarray

Return the mask of a masked array, or full array of False.

Examples

```

>>> import numpy as np
>>> import numpy.ma as ma
>>> a = ma.masked_equal([[1,2],[3,4]], 2)
>>> a
masked_array(
  data=[[1, --],
        [3, 4]],
  mask=[[False,  True],
        [False, False]],
  fill_value=2)
>>> ma.getmask(a)
array([[False,  True],
       [False, False]])

```

Equivalently use the *MaskedArray* *mask* attribute.

```

>>> a.mask
array([[False,  True],
       [False, False]])

```

Result when mask == *nomask*

```

>>> b = ma.masked_array([[1,2],[3,4]])
>>> b
masked_array(
  data=[[1, 2],
        [3, 4]],
  mask=False,
  fill_value=999999)
>>> ma.nomask
False
>>> ma.getmask(b) == ma.nomask
True
>>> b.mask == ma.nomask
True

```

`ma.getmaskarray(arr)`

Return the mask of a masked array, or full boolean array of False.

Return the mask of *arr* as an ndarray if *arr* is a *MaskedArray* and the mask is not *nomask*, else return a full boolean array of False of the same shape as *arr*.

Parameters

arr

[array_like] Input *MaskedArray* for which the mask is required.

See also:

getmask

Return the mask of a masked array, or nomask.

getdata

Return the data of a masked array as an ndarray.

Examples

```

>>> import numpy as np
>>> import numpy.ma as ma
>>> a = ma.masked_equal([[1,2],[3,4]], 2)
>>> a
masked_array(
  data=[[1, --],
        [3, 4]],
  mask=[[False,  True],
        [False, False]],
  fill_value=2)
>>> ma.getmaskarray(a)
array([[False,  True],
       [False, False]])

```

Result when mask == nomask

```

>>> b = ma.masked_array([[1,2],[3,4]])
>>> b
masked_array(
  data=[[1, 2],
        [3, 4]],
  mask=False,

```

(continues on next page)

(continued from previous page)

```

    fill_value=999999)
>>> ma.getmaskarray(b)
array([[False, False],
       [False, False]])

```

`ma.getdata(a, subok=True)`

Return the data of a masked array as an ndarray.

Return the data of *a* (if any) as an ndarray if *a* is a MaskedArray, else return *a* as an ndarray or subclass (depending on *subok*) if not.

Parameters

a

[array_like] Input MaskedArray, alternatively an ndarray or a subclass thereof.

subok

[bool] Whether to force the output to be a *pure* ndarray (False) or to return a subclass of ndarray if appropriate (True, default).

See also:

[*getmask*](#)

Return the mask of a masked array, or nomask.

[*getmaskarray*](#)

Return the mask of a masked array, or full array of False.

Examples

```

>>> import numpy as np
>>> import numpy.ma as ma
>>> a = ma.masked_equal([[1,2],[3,4]], 2)
>>> a
masked_array(
  data=[[1, --],
        [3, 4]],
  mask=[[False,  True],
        [False, False]],
  fill_value=2)
>>> ma.getdata(a)
array([[1, 2],
       [3, 4]])

```

Equivalently use the MaskedArray *data* attribute.

```

>>> a.data
array([[1, 2],
       [3, 4]])

```

`ma.nonzero(self)`

Return the indices of unmasked elements that are not zero.

Returns a tuple of arrays, one for each dimension, containing the indices of the non-zero elements in that dimension. The corresponding non-zero values can be obtained with:

```
a[a.nonzero()]
```

To group the indices by element, rather than dimension, use instead:

```
np.transpose(a.nonzero())
```

The result of this is always a 2d array, with a row for each non-zero element.

Parameters

None

Returns

tuple_of_arrays

[tuple] Indices of elements that are non-zero.

See also:

numpy.nonzero

Function operating on ndarrays.

flatnonzero

Return indices that are non-zero in the flattened version of the input array.

numpy.ndarray.nonzero

Equivalent ndarray method.

count_nonzero

Counts the number of non-zero elements in the input array.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = ma.array(np.eye(3))
>>> x
masked_array(
  data=[[1., 0., 0.],
        [0., 1., 0.],
        [0., 0., 1.]],
  mask=False,
  fill_value=1e+20)
>>> x.nonzero()
(array([0, 1, 2]), array([0, 1, 2]))
```

Masked elements are ignored.

```
>>> x[1, 1] = ma.masked
>>> x
masked_array(
  data=[[1.0, 0.0, 0.0],
        [0.0, --, 0.0],
        [0.0, 0.0, 1.0]],
  mask=[[False, False, False],
        [False, True, False],
        [False, False, False]],
  fill_value=1e+20)
```

(continues on next page)

(continued from previous page)

```
>>> x.nonzero()
(array([0, 2]), array([0, 2]))
```

Indices can also be grouped by element.

```
>>> np.transpose(x.nonzero())
array([[0, 0],
       [2, 2]])
```

A common use for `nonzero` is to find the indices of an array, where a condition is True. Given an array *a*, the condition *a* > 3 is a boolean array and since False is interpreted as 0, `ma.nonzero(a > 3)` yields the indices of the *a* where the condition is true.

```
>>> a = ma.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
>>> a > 3
masked_array(
  data=[[False, False, False],
        [ True,  True,  True],
        [ True,  True,  True]],
  mask=False,
  fill_value=True)
>>> ma.nonzero(a > 3)
(array([1, 1, 1, 2, 2, 2]), array([0, 1, 2, 0, 1, 2]))
```

The `nonzero` method of the condition array can also be called.

```
>>> (a > 3).nonzero()
(array([1, 1, 1, 2, 2, 2]), array([0, 1, 2, 0, 1, 2]))
```

ma.shape (*obj*)

Return the shape of an array.

Parameters

a
[array_like] Input array.

Returns

shape
[tuple of ints] The elements of the shape tuple give the lengths of the corresponding array dimensions.

See also:

len

`len(a)` is equivalent to `np.shape(a)[0]` for N-D arrays with $N \geq 1$.

ndarray.shape

Equivalent array method.

Examples

```
>>> import numpy as np
>>> np.shape(np.eye(3))
(3, 3)
>>> np.shape([[1, 3]])
(1, 2)
>>> np.shape([0])
(1,)
>>> np.shape(0)
()
```

```
>>> a = np.array([(1, 2), (3, 4), (5, 6)],
...               dtype=[('x', 'i4'), ('y', 'i4')])
>>> np.shape(a)
(3,)
>>> a.shape
(3,)
```

`ma.size(obj, axis=None)`

Return the number of elements along a given axis.

Parameters

a

[array_like] Input data.

axis

[None or int or tuple of ints, optional] Axis or axes along which the elements are counted. By default, give the total number of elements.

Changed in version 2.4: Extended to accept multiple axes.

Returns

element_count

[int] Number of elements along the specified axis.

See also:

[shape](#)

dimensions of array

[ndarray.shape](#)

dimensions of array

[ndarray.size](#)

number of elements in array

Examples

```
>>> import numpy as np
>>> a = np.array([[1,2,3],[4,5,6]])
>>> np.size(a)
6
>>> np.size(a,axis=1)
3
>>> np.size(a,axis=0)
2
>>> np.size(a,axis=(0,1))
6
```

`ma.is_masked(x)`

Determine whether input has masked values.

Accepts any object as input, but always returns False unless the input is a MaskedArray containing masked values.

Parameters

x

[array_like] Array to check for masked values.

Returns

result

[bool] True if *x* is a MaskedArray with masked values, False otherwise.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = ma.masked_equal([0, 1, 0, 2, 3], 0)
>>> x
masked_array(data=[--, 1, --, 2, 3],
             mask=[ True, False,  True, False, False],
             fill_value=0)
>>> ma.is_masked(x)
True
>>> x = ma.masked_equal([0, 1, 0, 2, 3], 42)
>>> x
masked_array(data=[0, 1, 0, 2, 3],
             mask=False,
             fill_value=42)
>>> ma.is_masked(x)
False
```

Always returns False if *x* isn't a MaskedArray.

```
>>> x = [False, True, False]
>>> ma.is_masked(x)
False
>>> x = 'a string'
>>> ma.is_masked(x)
False
```

`ma.is_mask(m)`

Return True if *m* is a valid, standard mask.

This function does not check the contents of the input, only that the type is `MaskType`. In particular, this function returns False if the mask has a flexible dtype.

Parameters

m

[array_like] Array to test.

Returns

result

[bool] True if *m.dtype.type* is `MaskType`, False otherwise.

See also:

[`ma.isMaskedArray`](#)

Test whether input is an instance of `MaskedArray`.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> m = ma.masked_equal([0, 1, 0, 2, 3], 0)
>>> m
masked_array(data=[--, 1, --, 2, 3],
             mask=[ True, False,  True, False, False],
             fill_value=0)
>>> ma.is_mask(m)
False
>>> ma.is_mask(m.mask)
True
```

Input must be an ndarray (or have similar attributes) for it to be considered a valid mask.

```
>>> m = [False, True, False]
>>> ma.is_mask(m)
False
>>> m = np.array([False, True, False])
>>> m
array([False,  True, False])
>>> ma.is_mask(m)
True
```

Arrays with complex dtypes don't return True.

```
>>> dtype = np.dtype({'names': ['monty', 'python'],
...                   'formats': [bool, bool]})
>>> dtype
dtype([('monty', '<b1'), ('python', '<b1')])
>>> m = np.array([(True, False), (False, True), (True, False)],
...             dtype=dtype)
>>> m
array([( True, False), (False,  True), ( True, False)],
      dtype=[('monty', '?'), ('python', '?')])
```

(continues on next page)

(continued from previous page)

```
>>> ma.is_mask(m)
False
```

`ma.isMaskedArray(x)`

Test whether input is an instance of MaskedArray.

This function returns True if *x* is an instance of MaskedArray and returns False otherwise. Any object is accepted as input.

Parameters

x
[object] Object to test.

Returns

result
[bool] True if *x* is a MaskedArray.

See also:

[*isMA*](#)

Alias to isMaskedArray.

[*isarray*](#)

Alias to isMaskedArray.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.eye(3, 3)
>>> a
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
>>> m = ma.masked_values(a, 0)
>>> m
masked_array(
  data=[[1.0, --, --],
        [--, 1.0, --],
        [--, --, 1.0]],
  mask=[[False,  True,  True],
        [ True, False,  True],
        [ True,  True, False]],
  fill_value=0.0)
>>> ma.isMaskedArray(a)
False
>>> ma.isMaskedArray(m)
True
>>> ma.isMaskedArray([0, 1, 2])
False
```

`ma.isMA(x)`

Test whether input is an instance of MaskedArray.

This function returns True if *x* is an instance of MaskedArray and returns False otherwise. Any object is accepted as input.

Parameters

x
[object] Object to test.

Returns

result
[bool] True if *x* is a MaskedArray.

See also:*isMA*

Alias to isMaskedArray.

isarray

Alias to isMaskedArray.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.eye(3, 3)
>>> a
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
>>> m = ma.masked_values(a, 0)
>>> m
masked_array(
  data=[[1.0, --, --],
        [--, 1.0, --],
        [--, --, 1.0]],
  mask=[[False,  True,  True],
        [ True, False,  True],
        [ True,  True, False]],
  fill_value=0.0)
>>> ma.isMaskedArray(a)
False
>>> ma.isMaskedArray(m)
True
>>> ma.isMaskedArray([0, 1, 2])
False
```

`ma.isarray(x)`

Test whether input is an instance of MaskedArray.

This function returns True if *x* is an instance of MaskedArray and returns False otherwise. Any object is accepted as input.

Parameters

x
[object] Object to test.

Returns

result

[bool] True if *x* is a MaskedArray.

See also:***isMA***

Alias to `isMaskedArray`.

isarray

Alias to `isMaskedArray`.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.eye(3, 3)
>>> a
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
>>> m = ma.masked_values(a, 0)
>>> m
masked_array(
  data=[[1.0, --, --],
        [--, 1.0, --],
        [--, --, 1.0]],
  mask=[[False,  True,  True],
        [ True, False,  True],
        [ True,  True, False]],
  fill_value=0.0)
>>> ma.isMaskedArray(a)
False
>>> ma.isMaskedArray(m)
True
>>> ma.isMaskedArray([0, 1, 2])
False
```

`ma.isin` (*element*, *test_elements*, *assume_unique=False*, *invert=False*)

Calculates *element* in *test_elements*, broadcasting over *element* only.

The output is always a masked array of the same shape as *element*. See [numpy.isin](#) for more details.

See also:***in1d***

Flattened version of this function.

numpy.isin

Equivalent function for ndarrays.

Examples

```
>>> import numpy as np
>>> element = np.ma.array([1, 2, 3, 4, 5, 6])
>>> test_elements = [0, 2]
>>> np.ma.isin(element, test_elements)
masked_array(data=[False,  True, False, False, False, False],
             mask=False,
             fill_value=True)
```

`ma.in1d` (*ar1*, *ar2*, *assume_unique=False*, *invert=False*)

Test whether each element of an array is also present in a second array.

The output is always a masked array.

We recommend using `isin` instead of `in1d` for new code.

See also:

`isin`

Version of this function that preserves the shape of *ar1*.

Examples

```
>>> import numpy as np
>>> ar1 = np.ma.array([0, 1, 2, 5, 0])
>>> ar2 = [0, 2]
>>> np.ma.in1d(ar1, ar2)
masked_array(data=[ True, False,  True, False,  True],
             mask=False,
             fill_value=True)
```

`ma.unique` (*ar1*, *return_index=False*, *return_inverse=False*)

Finds the unique elements of an array.

Masked values are considered the same element (masked). The output array is always a masked array. See `numpy.unique` for more details.

See also:

`numpy.unique`

Equivalent function for ndarrays.

Examples

```
>>> import numpy as np
>>> a = [1, 2, 1000, 2, 3]
>>> mask = [0, 0, 1, 0, 0]
>>> masked_a = np.ma.masked_array(a, mask)
>>> masked_a
masked_array(data=[1, 2, --, 2, 3],
             mask=[False, False,  True, False, False],
             fill_value=999999)
>>> np.ma.unique(masked_a)
masked_array(data=[1, 2, 3, --],
```

(continues on next page)

(continued from previous page)

```

        mask=[False, False, False,  True],
        fill_value=999999)
>>> np.ma.unique(masked_a, return_index=True)
(masked_array(data=[1, 2, 3,  --],
               mask=[False, False, False,  True],
               fill_value=999999), array([0, 1, 4, 2]))
>>> np.ma.unique(masked_a, return_inverse=True)
(masked_array(data=[1, 2, 3,  --],
               mask=[False, False, False,  True],
               fill_value=999999), array([0, 1, 3, 1, 2]))
>>> np.ma.unique(masked_a, return_index=True, return_inverse=True)
(masked_array(data=[1, 2, 3,  --],
               mask=[False, False, False,  True],
               fill_value=999999), array([0, 1, 4, 2]), array([0, 1, 3, 1, 2]))

```

method

`ma.MaskedArray.all` (*axis=None, out=None, keepdims=<no value>*)

Returns True if all elements evaluate to True.

The output array is masked where all the values along the given axis are masked: if the output would have been a scalar and that all the values are masked, then the output is *masked*.

Refer to [numpy.all](#) for full documentation.

See also:

[numpy.ndarray.all](#)

corresponding function for ndarrays

[numpy.all](#)

equivalent function

Examples

```

>>> import numpy as np
>>> np.ma.array([1,2,3]).all()
True
>>> a = np.ma.array([1,2,3], mask=True)
>>> (a.all() is np.ma.masked)
True

```

method

`ma.MaskedArray.any` (*axis=None, out=None, keepdims=<no value>*)

Returns True if any of the elements of *a* evaluate to True.

Masked values are considered as False during computation.

Refer to [numpy.any](#) for full documentation.

See also:

[numpy.ndarray.any](#)

corresponding function for ndarrays

[numpy.any](#)

equivalent function

method

`ma.MaskedArray.count` (*axis=None*, *keepdims=<no value>*)

Count the non-masked elements of the array along the given axis.

Parameters

axis

[None or int or tuple of ints, optional] Axis or axes along which the count is performed. The default, None, performs the count over all the dimensions of the input array. *axis* may be negative, in which case it counts from the last to the first axis. If this is a tuple of ints, the count is performed on multiple axes, instead of a single axis or all the axes as before.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the array.

Returns

result

[ndarray or scalar] An array with the same shape as the input array, with the specified axis removed. If the array is a 0-d array, or if *axis* is None, a scalar is returned.

See also:

[*ma.count_masked*](#)

Count masked elements in array or along a given axis.

Examples

```
>>> import numpy.ma as ma
>>> a = ma.arange(6).reshape((2, 3))
>>> a[1, :] = ma.masked
>>> a
masked_array(
  data=[[0, 1, 2],
        [--, --, --]],
  mask=[[False, False, False],
        [ True,  True,  True]],
  fill_value=999999)
>>> a.count()
3
```

When the *axis* keyword is specified an array of appropriate size is returned.

```
>>> a.count(axis=0)
array([1, 1, 1])
>>> a.count(axis=1)
array([3, 0])
```

method

`ma.MaskedArray.nonzero` ()

Return the indices of unmasked elements that are not zero.

Returns a tuple of arrays, one for each dimension, containing the indices of the non-zero elements in that dimension. The corresponding non-zero values can be obtained with:

```
a[a.nonzero()]
```

To group the indices by element, rather than dimension, use instead:

```
np.transpose(a.nonzero())
```

The result of this is always a 2d array, with a row for each non-zero element.

Parameters

None

Returns

tuple_of_arrays

[tuple] Indices of elements that are non-zero.

See also:

numpy.nonzero

Function operating on ndarrays.

flatnonzero

Return indices that are non-zero in the flattened version of the input array.

numpy.ndarray.nonzero

Equivalent ndarray method.

count_nonzero

Counts the number of non-zero elements in the input array.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = ma.array(np.eye(3))
>>> x
masked_array(
  data=[[1., 0., 0.],
        [0., 1., 0.],
        [0., 0., 1.]],
  mask=False,
  fill_value=1e+20)
>>> x.nonzero()
(array([0, 1, 2]), array([0, 1, 2]))
```

Masked elements are ignored.

```
>>> x[1, 1] = ma.masked
>>> x
masked_array(
  data=[[1.0, 0.0, 0.0],
        [0.0, --, 0.0],
        [0.0, 0.0, 1.0]],
  mask=[[False, False, False],
        [False, True, False],
        [False, False, False]],
  fill_value=1e+20)
```

(continues on next page)

(continued from previous page)

```
>>> x.nonzero()
(array([0, 2]), array([0, 2]))
```

Indices can also be grouped by element.

```
>>> np.transpose(x.nonzero())
array([[0, 0],
       [2, 2]])
```

A common use for `nonzero` is to find the indices of an array, where a condition is `True`. Given an array *a*, the condition *a* > 3 is a boolean array and since `False` is interpreted as 0, `ma.nonzero(a > 3)` yields the indices of the *a* where the condition is true.

```
>>> a = ma.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
>>> a > 3
masked_array(
  data=[[False, False, False],
        [ True,  True,  True],
        [ True,  True,  True]],
  mask=False,
  fill_value=True)
>>> ma.nonzero(a > 3)
(array([1, 1, 1, 2, 2, 2]), array([0, 1, 2, 0, 1, 2]))
```

The `nonzero` method of the condition array can also be called.

```
>>> (a > 3).nonzero()
(array([1, 1, 1, 2, 2, 2]), array([0, 1, 2, 0, 1, 2]))
```

<code>ma.MaskedArray.data</code>	Returns the underlying data, as a view of the masked array.
<code>ma.MaskedArray.mask</code>	Current mask.
<code>ma.MaskedArray.recordmask</code>	Get or set the mask of the array if it has no named fields.

Manipulating a MaskedArray

Changing the shape

<code>ma.ravel(self[, order])</code>	Returns a 1D version of self, as a view.
<code>ma.reshape(a, new_shape[, order])</code>	Returns an array containing the same data with a new shape.
<code>ma.resize(x, new_shape)</code>	Return a new masked array with the specified size and shape.
<code>ma.MaskedArray.flatten([order])</code>	Return a copy of the array collapsed into one dimension.
<code>ma.MaskedArray.ravel([order])</code>	Returns a 1D version of self, as a view.
<code>ma.MaskedArray.reshape(*s, **kwargs)</code>	Returns a reshaped masked array without changing its data.
<code>ma.MaskedArray.resize(newshape[, refcheck, ...])</code>	

`ma.ravel (self, order='C')`

Returns a 1D version of self, as a view.

Parameters

order

[{'C', 'F', 'A', 'K'}, optional] The elements of *a* are read using this index order. 'C' means to index the elements in C-like order, with the last axis index changing fastest, back to the first axis index changing slowest. 'F' means to index the elements in Fortran-like index order, with the first index changing fastest, and the last index changing slowest. Note that the 'C' and 'F' options take no account of the memory layout of the underlying array, and only refer to the order of axis indexing. 'A' means to read the elements in Fortran-like index order if *m* is Fortran *contiguous* in memory, C-like order otherwise. 'K' means to read the elements in the order they occur in memory, except for reversing the data when strides are negative. By default, 'C' index order is used. (Masked arrays currently use 'A' on the data when 'K' is passed.)

Returns

MaskedArray

Output view is of shape `(self.size,)` (or `(np.ma.product(self.shape),)`).

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[1,2,3],[4,5,6],[7,8,9]], mask=[0] + [1,0]*4)
>>> x
masked_array(
  data=[[1, --, 3],
        [--, 5, --],
        [7, --, 9]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=999999)
>>> x.ravel()
masked_array(data=[1, --, 3, --, 5, --, 7, --, 9],
             mask=[False,  True, False,  True, False,  True, False,  True,
                   False],
             fill_value=999999)
```

`ma.reshape (a, new_shape, order='C')`

Returns an array containing the same data with a new shape.

Refer to [MaskedArray.reshape](#) for full documentation.

See also:

[MaskedArray.reshape](#)

equivalent function

Examples

Reshaping a 1-D array:

```
>>> a = np.ma.array([1, 2, 3, 4])
>>> np.ma.reshape(a, (2, 2))
masked_array(
  data=[[1, 2],
        [3, 4]],
  mask=False,
  fill_value=999999)
```

Reshaping a 2-D array:

```
>>> b = np.ma.array([[1, 2], [3, 4]])
>>> np.ma.reshape(b, (1, 4))
masked_array(data=[[1, 2, 3, 4]],
             mask=False,
             fill_value=999999)
```

Reshaping a 1-D array with a mask:

```
>>> c = np.ma.array([1, 2, 3, 4], mask=[False, True, False, False])
>>> np.ma.reshape(c, (2, 2))
masked_array(
  data=[[1, --],
        [3, 4]],
  mask=[[False,  True],
        [False, False]],
  fill_value=999999)
```

`ma.resize(x, new_shape)`

Return a new masked array with the specified size and shape.

This is the masked equivalent of the `numpy.resize` function. The new array is filled with repeated copies of *x* (in the order that the data are stored in memory). If *x* is masked, the new array will be masked, and the new mask will be a repetition of the old one.

See also:

`numpy.resize`

Equivalent function in the top level NumPy module.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = ma.array([[1, 2], [3, 4]])
>>> a[0, 1] = ma.masked
>>> a
masked_array(
  data=[[1, --],
        [3, 4]],
  mask=[[False,  True],
        [False, False]],
  fill_value=999999)
```

(continues on next page)

(continued from previous page)

```
>>> np.resize(a, (3, 3))
masked_array(
  data=[[1, 2, 3],
        [4, 1, 2],
        [3, 4, 1]],
  mask=False,
  fill_value=999999)
>>> ma.resize(a, (3, 3))
masked_array(
  data=[[1, --, 3],
        [4, 1, --],
        [3, 4, 1]],
  mask=[[False,  True, False],
        [False, False,  True],
        [False, False, False]],
  fill_value=999999)
```

A MaskedArray is always returned, regardless of the input type.

```
>>> a = np.array([[1, 2], [3, 4]])
>>> ma.resize(a, (3, 3))
masked_array(
  data=[[1, 2, 3],
        [4, 1, 2],
        [3, 4, 1]],
  mask=False,
  fill_value=999999)
```

method

`ma.MaskedArray.flatten (order='C')`

Return a copy of the array collapsed into one dimension.

Parameters

order

[{'C', 'F', 'A', 'K'}, optional] 'C' means to flatten in row-major (C-style) order. 'F' means to flatten in column-major (Fortran- style) order. 'A' means to flatten in column-major order if *a* is Fortran *contiguous* in memory, row-major order otherwise. 'K' means to flatten *a* in the order the elements occur in memory. The default is 'C'.

Returns

y

[ndarray] A copy of the input array, flattened to one dimension.

See also:

[*ravel*](#)

Return a flattened array.

[*flat*](#)

A 1-D flat iterator over the array.

Examples

```
>>> import numpy as np
>>> a = np.array([[1,2], [3,4]])
>>> a.flatten()
array([1, 2, 3, 4])
>>> a.flatten('F')
array([1, 3, 2, 4])
```

method

`ma.MaskedArray.ravel (order='C')`

Returns a 1D version of self, as a view.

Parameters

order

[{'C', 'F', 'A', 'K'}, optional] The elements of *a* are read using this index order. 'C' means to index the elements in C-like order, with the last axis index changing fastest, back to the first axis index changing slowest. 'F' means to index the elements in Fortran-like index order, with the first index changing fastest, and the last index changing slowest. Note that the 'C' and 'F' options take no account of the memory layout of the underlying array, and only refer to the order of axis indexing. 'A' means to read the elements in Fortran-like index order if *m* is Fortran *contiguous* in memory, C-like order otherwise. 'K' means to read the elements in the order they occur in memory, except for reversing the data when strides are negative. By default, 'C' index order is used. (Masked arrays currently use 'A' on the data when 'K' is passed.)

Returns

MaskedArray

Output view is of shape `(self.size,)` (or `(np.ma.product(self.shape),)`).

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[1,2,3],[4,5,6],[7,8,9]], mask=[0] + [1,0]*4)
>>> x
masked_array(
  data=[[1, --, 3],
        [--, 5, --],
        [7, --, 9]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=999999)
>>> x.ravel()
masked_array(data=[1, --, 3, --, 5, --, 7, --, 9],
             mask=[False,  True, False,  True, False,  True, False,  True,
                   False],
             fill_value=999999)
```

method

`ma.MaskedArray.reshape (*s, **kwargs)`

Returns a reshaped masked array without changing its data.

Returns a masked array containing the same data, but with a new shape. The result is a view on the original array; if this is not possible, a `ValueError` is raised.

Parameters**shape**

[int or tuple of ints] The new shape should be compatible with the original shape. If an integer is supplied, then the result will be a 1-D array of that length.

order

['C', 'F'], optional] Determines whether the array data should be viewed as in C (row-major) or FORTRAN (column-major) order.

Returns**reshaped_array**

[array] A new view on the array.

See also:*reshape*

Equivalent function in the masked array module.

numpy.ndarray.reshape

Equivalent method on ndarray object.

numpy.reshape

Equivalent function in the NumPy module.

Notes

By default, the reshaping operation will make a copy if a view with different strides is not possible. To ensure a view, pass `copy=False`.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[1,2], [3,4]], mask=[1,0,0,1])
>>> x
masked_array(
  data=[--, 2],
        [3, --]],
  mask=[[ True, False],
        [False, True]],
  fill_value=999999)
>>> x = x.reshape((4,1))
>>> x
masked_array(
  data=[--,
        2],
        [3],
        [--]],
  mask=[[ True],
        [False],
        [False],
        [ True]],
  fill_value=999999)
```

method

`ma.MaskedArray.resize` (*newshape*, *refcheck=True*, *order=False*)

Warning: This method does nothing, except raise a `ValueError` exception. A masked array does not own its data and therefore cannot safely be resized in place. Use the `numpy.ma.resize` function instead.

This method is difficult to implement safely and may be deprecated in future releases of NumPy.

Modifying axes

<code>ma.swapaxes(a.swapaxes)</code>	Return a view of the array with <i>axis1</i> and <i>axis2</i> interchanged.
<code>ma.transpose(a[, axes])</code>	Permute the dimensions of an array.
<code>ma.MaskedArray.swapaxes(axis1, axis2, /)</code>	Return a view of the array with <i>axis1</i> and <i>axis2</i> interchanged.
<code>ma.MaskedArray.transpose(*axes)</code>	Returns a view of the array with axes transposed.

`ma.swapaxes` (*self*, **args*, ***params*) *a.swapaxes(axis1, axis2, /)*

`ma.swapaxes` (*axis1*, *axis2*, /) → `None`

Return a view of the array with *axis1* and *axis2* interchanged.

Refer to `numpy.swapaxes` for full documentation.

See also:

`numpy.swapaxes`
equivalent function

`ma.transpose` (*a*, *axes=None*)

Permute the dimensions of an array.

This function is exactly equivalent to `numpy.transpose`.

See also:

`numpy.transpose`
Equivalent function in top-level NumPy module.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = ma.arange(4).reshape((2,2))
>>> x[1, 1] = ma.masked
>>> x
masked_array(
  data=[[0, 1],
        [2, --]],
  mask=[[False, False],
        [False,  True]],
  fill_value=999999)
```

```
>>> ma.transpose(x)
masked_array(
  data=[[0, 2],
        [1, --]],
  mask=[[False, False],
        [False,  True]],
  fill_value=999999)
```

method

`ma.MaskedArray.swapaxes` (*axis1*, *axis2*, /)

Return a view of the array with *axis1* and *axis2* interchanged.

Refer to [`numpy.swapaxes`](#) for full documentation.

See also:

[`numpy.swapaxes`](#)
equivalent function

method

`ma.MaskedArray.transpose` (**axes*)

Returns a view of the array with axes transposed.

Refer to [`numpy.transpose`](#) for full documentation.

Parameters

axes

[None, tuple of ints, or *n* ints]

- None or no argument: reverses the order of the axes.
- tuple of ints: *i* in the *j*-th place in the tuple means that the array's *i*-th axis becomes the transposed array's *j*-th axis.
- *n* ints: same as an *n*-tuple of the same ints (this form is intended simply as a “convenience” alternative to the tuple form).

Returns

P

[ndarray] View of the array with its axes suitably permuted.

See also:

[`transpose`](#)
Equivalent function.

[`ndarray.T`](#)
Array property returning the array transposed.

[`ndarray.reshape`](#)
Return a reshaped ndarray without changing data.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> a
array([[1, 2],
       [3, 4]])
>>> a.transpose()
array([[1, 3],
       [2, 4]])
>>> a.transpose((1, 0))
array([[1, 3],
       [2, 4]])
>>> a.transpose(1, 0)
array([[1, 3],
       [2, 4]])
```

```
>>> a = np.array([1, 2, 3, 4])
>>> a
array([1, 2, 3, 4])
>>> a.transpose()
array([1, 2, 3, 4])
```

Changing the number of dimensions

<code>ma.atleast_1d(*arys)</code>	Convert inputs to arrays with at least one dimension.
<code>ma.atleast_2d(*arys)</code>	View inputs as arrays with at least two dimensions.
<code>ma.atleast_3d(*arys)</code>	View inputs as arrays with at least three dimensions.
<code>ma.expand_dims(a, axis)</code>	Expand the shape of an array.
<code>ma.squeeze(a[, axis, fill_value, hardmask])</code>	Remove axes of length one from <i>a</i> .
<code>ma.MaskedArray.squeeze([axis])</code>	Remove axes of length one from <i>a</i> .
<code>ma.stack(arrays[, axis, out, dtype, casting])</code>	Join a sequence of arrays along a new axis.
<code>ma.column_stack(tup)</code>	Stack 1-D arrays as columns into a 2-D array.
<code>ma.concatenate(arrays[, axis])</code>	Concatenate a sequence of arrays along the given axis.
<code>ma.dstack(tup)</code>	Stack arrays in sequence depth wise (along third axis).
<code>ma.hstack(tup, *[, dtype, casting])</code>	Stack arrays in sequence horizontally (column wise).
<code>ma.hsplit(ary, indices_or_sections)</code>	Split an array into multiple sub-arrays horizontally (column-wise).
<code>ma.mr_</code>	Translate slice objects to concatenation along the first axis.
<code>ma.vstack(tup, *[, dtype, casting])</code>	Stack arrays in sequence vertically (row wise).

`ma.atleast_1d(*arys)`

Convert inputs to arrays with at least one dimension.

Scalar inputs are converted to 1-dimensional arrays, whilst higher-dimensional inputs are preserved.

Parameters

arys1, arys2, ...

[array_like] One or more input arrays.

Returns

ret

[ndarray] An array, or tuple of arrays, each with `a.ndim >= 1`. Copies are made only if necessary.

See also:*[atleast_2d](#)*, *[atleast_3d](#)***Notes**

The function is applied to both the `_data` and the `_mask`, if any.

Examples

```
>>> import numpy as np
>>> np.atleast_1d(1.0)
array([1.])
```

```
>>> x = np.arange(9.0).reshape(3,3)
>>> np.atleast_1d(x)
array([[0., 1., 2.],
       [3., 4., 5.],
       [6., 7., 8.]])
>>> np.atleast_1d(x) is x
True
```

```
>>> np.atleast_1d(1, [3, 4])
(array([1]), array([3, 4]))
```

ma.atleast_2d(**arys*)

View inputs as arrays with at least two dimensions.

Parameters**arys1, arys2, ...**

[array_like] One or more array-like sequences. Non-array inputs are converted to arrays. Arrays that already have two or more dimensions are preserved.

Returns**res, res2, ...**

[ndarray] An array, or tuple of arrays, each with `a.ndim >= 2`. Copies are avoided where possible, and views with two or more dimensions are returned.

See also:*[atleast_1d](#)*, *[atleast_3d](#)*

Notes

The function is applied to both the `_data` and the `_mask`, if any.

Examples

```
>>> import numpy as np
>>> np.atleast_2d(3.0)
array([[3.]])
```

```
>>> x = np.arange(3.0)
>>> np.atleast_2d(x)
array([[0., 1., 2.]])
>>> np.atleast_2d(x).base is x
True
```

```
>>> np.atleast_2d(1, [1, 2], [[1, 2]])
(array([[1]]), array([[1, 2]]), array([[1, 2]]))
```

`ma.atleast_3d(*arys)`

View inputs as arrays with at least three dimensions.

Parameters

arys1, arys2, ...

[array_like] One or more array-like sequences. Non-array inputs are converted to arrays. Arrays that already have three or more dimensions are preserved.

Returns

res1, res2, ...

[ndarray] An array, or tuple of arrays, each with `a.ndim >= 3`. Copies are avoided where possible, and views with three or more dimensions are returned. For example, a 1-D array of shape `(N,)` becomes a view of shape `(1, N, 1)`, and a 2-D array of shape `(M, N)` becomes a view of shape `(M, N, 1)`.

See also:

[`atleast\_1d`](#), [`atleast\_2d`](#)

Notes

The function is applied to both the `_data` and the `_mask`, if any.

Examples

```
>>> import numpy as np
>>> np.atleast_3d(3.0)
array([[[[3.]]]])
```

```
>>> x = np.arange(3.0)
>>> np.atleast_3d(x).shape
(1, 3, 1)
```

```
>>> x = np.arange(12.0).reshape(4,3)
>>> np.atleast_3d(x).shape
(4, 3, 1)
>>> np.atleast_3d(x).base is x.base # x is a reshape, so not base itself
True
```

```
>>> for arr in np.atleast_3d([1, 2], [[1, 2]], [[[1, 2]]]):
...     print(arr, arr.shape)
...
[[[1]
 [2]]] (1, 2, 1)
[[[1]
 [2]]] (1, 2, 1)
[[[1 2]]] (1, 1, 2)
```

ma.**expand_dims** (*a*, *axis*)

Expand the shape of an array.

Insert a new axis that will appear at the *axis* position in the expanded array shape.

Parameters

a

[array_like] Input array.

axis

[int or tuple of ints] Position in the expanded axes where the new axis (or axes) is placed.

Deprecated since version 1.13.0: Passing an axis where `axis > a.ndim` will be treated as `axis == a.ndim`, and passing `axis < -a.ndim - 1` will be treated as `axis == 0`. This behavior is deprecated.

Returns

result

[ndarray] View of *a* with the number of dimensions increased.

See also:

[*squeeze*](#)

The inverse operation, removing singleton dimensions

[*reshape*](#)

Insert, remove, and combine dimensions, and resize existing ones

[*atleast_1d*](#), [*atleast_2d*](#), [*atleast_3d*](#)

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2])
>>> x.shape
(2,)
```

The following is equivalent to `x[np.newaxis, :]` or `x[np.newaxis]`:

```
>>> y = np.expand_dims(x, axis=0)
>>> y
array([[1, 2]])
>>> y.shape
(1, 2)
```

The following is equivalent to `x[:, np.newaxis]`:

```
>>> y = np.expand_dims(x, axis=1)
>>> y
array([[1],
       [2]])
>>> y.shape
(2, 1)
```

`axis` may also be a tuple:

```
>>> y = np.expand_dims(x, axis=(0, 1))
>>> y
array([[[1, 2]]])
```

```
>>> y = np.expand_dims(x, axis=(2, 0))
>>> y
array([[[1],
       [2]]])
```

Note that some examples may use `None` instead of `np.newaxis`. These are the same objects:

```
>>> np.newaxis is None
True
```

ma.squeeze (*a*, *axis=None*, *, *fill_value=None*, *hardmask=False*)

Remove axes of length one from *a*.

Parameters

a

[array_like] Input data.

axis

[None or int or tuple of ints, optional] Selects a subset of the entries of length one in the shape. If an axis is selected with shape entry greater than one, an error is raised.

Returns

squeezed

[MaskedArray] The input array, but with all or a subset of the dimensions of length 1 removed. This is always *a* itself or a view into *a*. Note that if all axes are squeezed, the result is a 0d array and not a scalar.

Raises

ValueError

If *axis* is not `None`, and an axis being squeezed is not of length 1

See also:

[*expand_dims*](#)

The inverse operation, adding entries of length one

reshape

Insert, remove, and combine dimensions, and resize existing ones

Examples

```
>>> import numpy as np
>>> x = np.array([[[0], [1], [2]]])
>>> x.shape
(1, 3, 1)
>>> np.squeeze(x).shape
(3,)
>>> np.squeeze(x, axis=0).shape
(3, 1)
>>> np.squeeze(x, axis=1).shape
Traceback (most recent call last):
...
ValueError: cannot select an axis to squeeze out which has size
not equal to one
>>> np.squeeze(x, axis=2).shape
(1, 3)
>>> x = np.array([[1234]])
>>> x.shape
(1, 1)
>>> np.squeeze(x)
array(1234) # 0d array
>>> np.squeeze(x).shape
()
>>> np.squeeze(x) [()]
1234
```

method

`ma.MaskedArray.squeeze(axis=None)`

Remove axes of length one from *a*.

Refer to [numpy.squeeze](#) for full documentation.

See also:

[numpy.squeeze](#)

equivalent function

`ma.stack(arrays, axis=0, out=None, *, dtype=None, casting='same_kind')`

Join a sequence of arrays along a new axis.

The `axis` parameter specifies the index of the new axis in the dimensions of the result. For example, if `axis=0` it will be the first dimension and if `axis=-1` it will be the last dimension.

Parameters**arrays**

[sequence of ndarrays] Each array must have the same shape. In the case of a single ndarray array_like input, it will be treated as a sequence of arrays; i.e., each element along the zeroth axis is treated as a separate array.

axis

[int, optional] The axis in the result array along which the input arrays are stacked.

out

[ndarray, optional] If provided, the destination to place the result. The shape must be correct, matching that of what stack would have returned if no out argument were specified.

dtype

[str or dtype] If provided, the destination array will have this dtype. Cannot be provided together with *out*.

New in version 1.24.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'same_kind'.

New in version 1.24.

Returns**stacked**

[ndarray] The stacked array has one more dimension than the input arrays.

See also:***concatenate***

Join a sequence of arrays along an existing axis.

block

Assemble an nd-array from nested lists of blocks.

split

Split array into a list of multiple sub-arrays of equal size.

unstack

Split an array into a tuple of sub-arrays along an axis.

Notes

The function is applied to both the `_data` and the `_mask`, if any.

Examples

```
>>> import numpy as np
>>> rng = np.random.default_rng()
>>> arrays = [rng.normal(size=(3,4)) for _ in range(10)]
>>> np.stack(arrays, axis=0).shape
(10, 3, 4)
```

```
>>> np.stack(arrays, axis=1).shape
(3, 10, 4)
```

```
>>> np.stack(arrays, axis=2).shape
(3, 4, 10)
```

```
>>> a = np.array([1, 2, 3])
>>> b = np.array([4, 5, 6])
>>> np.stack((a, b))
```

(continues on next page)

(continued from previous page)

```
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> np.stack((a, b), axis=-1)
array([[1, 4],
       [2, 5],
       [3, 6]])
```

`ma.column_stack(tup)`

Stack 1-D arrays as columns into a 2-D array.

Take a sequence of 1-D arrays and stack them as columns to make a single 2-D array. 2-D arrays are stacked as-is, just like with *hstack*. 1-D arrays are turned into 2-D columns first.

Parameters

tup

[sequence of 1-D or 2-D arrays.] Arrays to stack. All of them must have the same first dimension.

Returns

stacked

[2-D array] The array formed by stacking the given arrays.

See also:

stack, *hstack*, *vstack*, *concatenate*

Notes

The function is applied to both the `_data` and the `_mask`, if any.

Examples

```
>>> import numpy as np
>>> a = np.array((1,2,3))
>>> b = np.array((4,5,6))
>>> np.column_stack((a,b))
array([[1, 4],
       [2, 5],
       [3, 6]])
```

`ma.concatenate(arrays, axis=0)`

Concatenate a sequence of arrays along the given axis.

Parameters

arrays

[sequence of array_like] The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).

axis

[int, optional] The axis along which the arrays will be joined. Default is 0.

Returns

result

[MaskedArray] The concatenated array with any masked entries preserved.

See also:

[*numpy.concatenate*](#)

Equivalent function in the top-level NumPy module.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = ma.arange(3)
>>> a[1] = ma.masked
>>> b = ma.arange(2, 5)
>>> a
masked_array(data=[0, --, 2],
             mask=[False,  True,  False],
             fill_value=999999)
>>> b
masked_array(data=[2, 3, 4],
             mask=False,
             fill_value=999999)
>>> ma.concatenate([a, b])
masked_array(data=[0, --, 2, 2, 3, 4],
             mask=[False,  True,  False,  False,  False,  False],
             fill_value=999999)
```

ma.dstack (*tup*)

Stack arrays in sequence depth wise (along third axis).

This is equivalent to concatenation along the third axis after 2-D arrays of shape (M,N) have been reshaped to $(M,N,1)$ and 1-D arrays of shape $(N,)$ have been reshaped to $(1,N,1)$. Rebuilds arrays divided by [*dsplit*](#).

This function makes most sense for arrays with up to 3 dimensions. For instance, for pixel-data with a height (first axis), width (second axis), and r/g/b channels (third axis). The functions [*concatenate*](#), [*stack*](#) and [*block*](#) provide more general stacking and concatenation operations.

Parameters

tup

[sequence of arrays] The arrays must have the same shape along all but the third axis. 1-D or 2-D arrays must have the same shape.

Returns

stacked

[ndarray] The array formed by stacking the given arrays, will be at least 3-D.

See also:

[*concatenate*](#)

Join a sequence of arrays along an existing axis.

[*stack*](#)

Join a sequence of arrays along a new axis.

[*block*](#)

Assemble an nd-array from nested lists of blocks.

vstack

Stack arrays in sequence vertically (row wise).

hstack

Stack arrays in sequence horizontally (column wise).

column_stack

Stack 1-D arrays as columns into a 2-D array.

dsplit

Split array along third axis.

Notes

The function is applied to both the `_data` and the `_mask`, if any.

Examples

```
>>> import numpy as np
>>> a = np.array((1,2,3))
>>> b = np.array((4,5,6))
>>> np.dstack((a,b))
array([[1, 4],
       [2, 5],
       [3, 6]])
```

```
>>> a = np.array([[1],[2],[3]])
>>> b = np.array([[4],[5],[6]])
>>> np.dstack((a,b))
array([[1, 4],
       [2, 5],
       [3, 6]])
```

ma.**hstack** (*tup*, *, *dtype=None*, *casting='same_kind'*)

Stack arrays in sequence horizontally (column wise).

This is equivalent to concatenation along the second axis, except for 1-D arrays where it concatenates along the first axis. Rebuilds arrays divided by *hsplit*.

This function makes most sense for arrays with up to 3 dimensions. For instance, for pixel-data with a height (first axis), width (second axis), and r/g/b channels (third axis). The functions *concatenate*, *stack* and *block* provide more general stacking and concatenation operations.

Parameters**tup**

[sequence of ndarrays] The arrays must have the same shape along all but the second axis, except 1-D arrays which can be any length. In the case of a single array_like input, it will be treated as a sequence of arrays; i.e., each element along the zeroth axis is treated as a separate array.

dtype

[str or dtype] If provided, the destination array will have this dtype. Cannot be provided together with *out*.

New in version 1.24.

casting

['no', 'equiv', 'safe', 'same_kind', 'unsafe'], optional] Controls what kind of data casting may occur. Defaults to 'same_kind'.

New in version 1.24.

Returns**stacked**

[ndarray] The array formed by stacking the given arrays.

See also:*concatenate*

Join a sequence of arrays along an existing axis.

stack

Join a sequence of arrays along a new axis.

block

Assemble an nd-array from nested lists of blocks.

vstack

Stack arrays in sequence vertically (row wise).

dstack

Stack arrays in sequence depth wise (along third axis).

column_stack

Stack 1-D arrays as columns into a 2-D array.

hsplit

Split an array into multiple sub-arrays horizontally (column-wise).

unstack

Split an array into a tuple of sub-arrays along an axis.

Notes

The function is applied to both the `_data` and the `_mask`, if any.

Examples

```
>>> import numpy as np
>>> a = np.array((1,2,3))
>>> b = np.array((4,5,6))
>>> np.hstack((a,b))
array([1, 2, 3, 4, 5, 6])
>>> a = np.array([[1],[2],[3]])
>>> b = np.array([[4],[5],[6]])
>>> np.hstack((a,b))
array([[1, 4],
       [2, 5],
       [3, 6]])
```

`ma.hsplitlet (ary, indices_or_sections)`

Split an array into multiple sub-arrays horizontally (column-wise).

Please refer to the [split](#) documentation. *hsplitlet* is equivalent to *split* with `axis=1`, the array is always split along the second axis except for 1-D arrays, where it is split at `axis=0`.

See also:

[split](#)

Split an array into multiple sub-arrays of equal size.

Notes

The function is applied to both the `_data` and the `_mask`, if any.

Examples

```
>>> import numpy as np
>>> x = np.arange(16.0).reshape(4, 4)
>>> x
array([[ 0.,  1.,  2.,  3.],
       [ 4.,  5.,  6.,  7.],
       [ 8.,  9., 10., 11.],
       [12., 13., 14., 15.]])
>>> np.hsplitlet(x, 2)
[array([[ 0.,  1.],
       [ 4.,  5.],
       [ 8.,  9.],
       [12., 13.]])],
      array([[ 2.,  3.],
       [ 6.,  7.],
       [10., 11.],
       [14., 15.]])]
>>> np.hsplitlet(x, np.array([3, 6]))
[array([[ 0.,  1.,  2.],
       [ 4.,  5.,  6.],
       [ 8.,  9., 10.],
       [12., 13., 14.]])],
      array([[ 3.],
       [ 7.],
       [11.],
       [15.]])],
      array([], shape=(4, 0), dtype=float64)]
```

With a higher dimensional array the split is still along the second axis.

```
>>> x = np.arange(8.0).reshape(2, 2, 2)
>>> x
array([[[0.,  1.],
       [2.,  3.]],
      [[4.,  5.],
       [6.,  7.]])])
>>> np.hsplitlet(x, 2)
[array([[[0.,  1.]],
       [[4.,  5.]]])],
```

(continues on next page)

(continued from previous page)

```
array([[[2.,  3.]],
       [[6.,  7.]])])
```

With a 1-D array, the split is along axis 0.

```
>>> x = np.array([0, 1, 2, 3, 4, 5])
>>> np.hsplit(x, 2)
[array([0, 1, 2]), array([3, 4, 5])]
```

`ma.mr_ = <numpy.ma.extras.mr_class object>`

Translate slice objects to concatenation along the first axis.

This is the masked array version of `r_`.

See also:

`r_`

Examples

```
>>> import numpy as np
>>> np.ma.mr_[np.ma.array([1,2,3]), 0, 0, np.ma.array([4,5,6])]
masked_array(data=[1, 2, 3, ..., 4, 5, 6],
              mask=False,
              fill_value=999999)
```

`ma.vstack(tup, *, dtype=None, casting='same_kind')`

Stack arrays in sequence vertically (row wise).

This is equivalent to concatenation along the first axis after 1-D arrays of shape $(N,)$ have been reshaped to $(1,N)$. Rebuilds arrays divided by `vsplit`.

This function makes most sense for arrays with up to 3 dimensions. For instance, for pixel-data with a height (first axis), width (second axis), and r/g/b channels (third axis). The functions `concatenate`, `stack` and `block` provide more general stacking and concatenation operations.

Parameters

`tup`

[sequence of ndarrays] The arrays must have the same shape along all but the first axis. 1-D arrays must have the same length. In the case of a single array_like input, it will be treated as a sequence of arrays; i.e., each element along the zeroth axis is treated as a separate array.

`dtype`

[str or dtype] If provided, the destination array will have this dtype. Cannot be provided together with `out`.

New in version 1.24.

`casting`

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'same_kind'.

New in version 1.24.

Returns

stacked

[ndarray] The array formed by stacking the given arrays, will be at least 2-D.

See also:*concatenate*

Join a sequence of arrays along an existing axis.

stack

Join a sequence of arrays along a new axis.

block

Assemble an nd-array from nested lists of blocks.

hstack

Stack arrays in sequence horizontally (column wise).

dstack

Stack arrays in sequence depth wise (along third axis).

column_stack

Stack 1-D arrays as columns into a 2-D array.

vsplit

Split an array into multiple sub-arrays vertically (row-wise).

unstack

Split an array into a tuple of sub-arrays along an axis.

Notes

The function is applied to both the `_data` and the `_mask`, if any.

Examples

```
>>> import numpy as np
>>> a = np.array([1, 2, 3])
>>> b = np.array([4, 5, 6])
>>> np.vstack((a,b))
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> a = np.array([[1], [2], [3]])
>>> b = np.array([[4], [5], [6]])
>>> np.vstack((a,b))
array([[1],
       [2],
       [3],
       [4],
       [5],
       [6]])
```

Joining arrays

<code>ma.concatenate(arrays[, axis])</code>	Concatenate a sequence of arrays along the given axis.
<code>ma.stack(arrays[, axis, out, dtype, casting])</code>	Join a sequence of arrays along a new axis.
<code>ma.vstack(tup, *[, dtype, casting])</code>	Stack arrays in sequence vertically (row wise).
<code>ma.hstack(tup, *[, dtype, casting])</code>	Stack arrays in sequence horizontally (column wise).
<code>ma.dstack(tup)</code>	Stack arrays in sequence depth wise (along third axis).
<code>ma.column_stack(tup)</code>	Stack 1-D arrays as columns into a 2-D array.
<code>ma.append(a, b[, axis])</code>	Append values to the end of an array.

`ma.append(a, b, axis=None)`

Append values to the end of an array.

Parameters

a

[array_like] Values are appended to a copy of this array.

b

[array_like] These values are appended to a copy of *a*. It must be of the correct shape (the same shape as *a*, excluding *axis*). If *axis* is not specified, *b* can be any shape and will be flattened before use.

axis

[int, optional] The axis along which *v* are appended. If *axis* is not given, both *a* and *b* are flattened before use.

Returns

append

[MaskedArray] A copy of *a* with *b* appended to *axis*. Note that *append* does not occur in-place: a new array is allocated and filled. If *axis* is None, the result is a flattened array.

See also:

numpy.append

Equivalent function in the top-level NumPy module.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = ma.masked_values([1, 2, 3], 2)
>>> b = ma.masked_values([[4, 5, 6], [7, 8, 9]], 7)
>>> ma.append(a, b)
masked_array(data=[1, --, 3, 4, 5, 6, --, 8, 9],
             mask=[False,  True, False, False, False, False,  True, False,
                   False],
             fill_value=999999)
```

Operations on masks

Creating a mask

<code>ma.make_mask(m[, copy, shrink, dtype])</code>	Create a boolean mask from an array.
<code>ma.make_mask_none(newshape[, dtype])</code>	Return a boolean mask of the given shape, filled with False.
<code>ma.mask_or(m1, m2[, copy, shrink])</code>	Combine two masks with the <code>logical_or</code> operator.
<code>ma.make_mask_descr(ndtype)</code>	Construct a dtype description list from a given dtype.

`ma.make_mask` (*m*, *copy*=False, *shrink*=True, *dtype*=<class 'numpy.bool'>)

Create a boolean mask from an array.

Return *m* as a boolean mask, creating a copy if necessary or requested. The function can accept any sequence that is convertible to integers, or `nomask`. Does not require that contents must be 0s and 1s, values of 0 are interpreted as False, everything else as True.

Parameters

m

[array_like] Potential mask.

copy

[bool, optional] Whether to return a copy of *m* (True) or *m* itself (False).

shrink

[bool, optional] Whether to shrink *m* to `nomask` if all its values are False.

dtype

[dtype, optional] Data-type of the output mask. By default, the output mask has a dtype of `MaskType (bool)`. If the dtype is flexible, each field has a boolean dtype. This is ignored when *m* is `nomask`, in which case `nomask` is always returned.

Returns

result

[ndarray] A boolean mask derived from *m*.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> m = [True, False, True, True]
>>> ma.make_mask(m)
array([ True, False,  True,  True])
>>> m = [1, 0, 1, 1]
>>> ma.make_mask(m)
array([ True, False,  True,  True])
>>> m = [1, 0, 2, -3]
>>> ma.make_mask(m)
array([ True, False,  True,  True])
```

Effect of the *shrink* parameter.

```
>>> m = np.zeros(4)
>>> m
array([0., 0., 0., 0.])
>>> ma.make_mask(m)
False
>>> ma.make_mask(m, shrink=False)
array([False, False, False, False])
```

Using a flexible *dtype*.

```
>>> m = [1, 0, 1, 1]
>>> n = [0, 1, 0, 0]
>>> arr = []
>>> for man, mouse in zip(m, n):
...     arr.append((man, mouse))
>>> arr
[(1, 0), (0, 1), (1, 0), (1, 0)]
>>> dtype = np.dtype({'names': ['man', 'mouse'],
...                   'formats': [np.int64, np.int64]})
>>> arr = np.array(arr, dtype=dtype)
>>> arr
array([(1, 0), (0, 1), (1, 0), (1, 0)],
      dtype=[('man', '<i8'), ('mouse', '<i8')])
>>> ma.make_mask(arr, dtype=dtype)
array([(True, False), (False, True), (True, False), (True, False)],
      dtype=[('man', '|b1'), ('mouse', '|b1')])
```

`ma.make_mask_none` (*newshape*, *dtype=None*)

Return a boolean mask of the given shape, filled with False.

This function returns a boolean ndarray with all entries False, that can be used in common mask manipulations. If a complex dtype is specified, the type of each field is converted to a boolean type.

Parameters

newshape

[tuple] A tuple indicating the shape of the mask.

dtype

[{None, dtype}, optional] If None, use a MaskType instance. Otherwise, use a new datatype with the same fields as *dtype*, converted to boolean types.

Returns

result

[ndarray] An ndarray of appropriate shape and dtype, filled with False.

See also:

make_mask

Create a boolean mask from an array.

make_mask_descr

Construct a dtype description list from a given dtype.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> ma.make_mask_none((3,))
array([False, False, False])
```

Defining a more complex dtype.

```
>>> dtype = np.dtype({'names': ['foo', 'bar'],
...                     'formats': [np.float32, np.int64]})
>>> dtype
dtype([('foo', '<f4'), ('bar', '<i8')])
>>> ma.make_mask_none((3,), dtype=dtype)
array([(False, False), (False, False), (False, False)],
      dtype=[('foo', '<b1'), ('bar', '<b1')])
```

`ma.mask_or` (*m1*, *m2*, *copy=False*, *shrink=True*)

Combine two masks with the `logical_or` operator.

The result may be a view on *m1* or *m2* if the other is *nomask* (i.e. `False`).

Parameters

m1, m2

[array_like] Input masks.

copy

[bool, optional] If `copy` is `False` and one of the inputs is *nomask*, return a view of the other input mask. Defaults to `False`.

shrink

[bool, optional] Whether to shrink the output to *nomask* if all its values are `False`. Defaults to `True`.

Returns

mask

[output mask] The result masks values that are masked in either *m1* or *m2*.

Raises

ValueError

If *m1* and *m2* have different flexible dtypes.

Examples

```
>>> import numpy as np
>>> m1 = np.ma.make_mask([0, 1, 1, 0])
>>> m2 = np.ma.make_mask([1, 0, 0, 0])
>>> np.ma.mask_or(m1, m2)
array([ True,  True,  True, False])
```

`ma.make_mask_descr` (*ndtype*)

Construct a dtype description list from a given dtype.

Returns a new dtype object, with the type of all fields in *ndtype* to a boolean type. Field names are not altered.

Parameters

ndtype

[dtype] The dtype to convert.

Returns**result**[dtype] A dtype that looks like *ndtype*, the type of all fields is boolean.**Examples**

```

>>> import numpy as np
>>> import numpy.ma as ma
>>> dtype = np.dtype({'names': ['foo', 'bar'],
...                   'formats': [np.float32, np.int64]})
>>> dtype
dtype([('foo', '<f4'), ('bar', '<i8')])
>>> ma.make_mask_descr(dtype)
dtype([('foo', '|b1'), ('bar', '|b1')])
>>> ma.make_mask_descr(np.float32)
dtype('bool')

```

Accessing a mask

<code>ma.getmask(a)</code>	Return the mask of a masked array, or nomask.
<code>ma.getmaskarray(arr)</code>	Return the mask of a masked array, or full boolean array of False.
<code>ma.masked_array.mask</code>	Current mask.

property

property `ma.masked_array.mask`

Current mask.

Finding masked data

<code>ma.ndenumerate(a[, compressed])</code>	Multidimensional index iterator.
<code>ma.flatnotmasked_contiguous(a)</code>	Find contiguous unmasked data in a masked array.
<code>ma.flatnotmasked_edges(a)</code>	Find the indices of the first and last unmasked values.
<code>ma.notmasked_contiguous(a[, axis])</code>	Find contiguous unmasked data in a masked array along the given axis.
<code>ma.notmasked_edges(a[, axis])</code>	Find the indices of the first and last unmasked values along an axis.
<code>ma.clump_masked(a)</code>	Returns a list of slices corresponding to the masked clumps of a 1-D array.
<code>ma.clump_unmasked(a)</code>	Return list of slices corresponding to the unmasked clumps of a 1-D array.

`ma.ndenumerate(a, compressed=True)`

Multidimensional index iterator.

Return an iterator yielding pairs of array coordinates and values, skipping elements that are masked. With *compressed=False*, `ma.masked` is yielded as the value of masked elements. This behavior differs from that of `numpy.ndenumerate`, which yields the value of the underlying data array.

Parameters

a

[array_like] An array with (possibly) masked elements.

compressed

[bool, optional] If True (default), masked elements are skipped.

See also:

[`numpy.ndenumerate`](#)

Equivalent function ignoring any mask.

Notes

New in version 1.23.0.

Examples

```
>>> import numpy as np
>>> a = np.ma.arange(9).reshape((3, 3))
>>> a[1, 0] = np.ma.masked
>>> a[1, 2] = np.ma.masked
>>> a[2, 1] = np.ma.masked
>>> a
masked_array(
  data=[[0, 1, 2],
        [--, 4, --],
        [6, --, 8]],
  mask=[[False, False, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=999999)
>>> for index, x in np.ma.ndenumerate(a):
...     print(index, x)
(0, 0) 0
(0, 1) 1
(0, 2) 2
(1, 1) 4
(2, 0) 6
(2, 2) 8
```

```
>>> for index, x in np.ma.ndenumerate(a, compressed=False):
...     print(index, x)
(0, 0) 0
(0, 1) 1
(0, 2) 2
(1, 0) --
(1, 1) 4
```

(continues on next page)

(continued from previous page)

```
(1, 2) --
(2, 0) 6
(2, 1) --
(2, 2) 8
```

`ma.flatnotmasked_contiguous(a)`

Find contiguous unmasked data in a masked array.

Parameters

a
[array_like] The input array.

Returns

slice_list
[list] A sorted sequence of *slice* objects (start index, end index).

See also:

flatnotmasked_edges, *notmasked_contiguous*, *notmasked_edges*
clump_masked, *clump_unmasked*

Notes

Only accepts 2-D arrays at most.

Examples

```
>>> import numpy as np
>>> a = np.ma.arange(10)
>>> np.ma.flatnotmasked_contiguous(a)
[slice(0, 10, None)]
```

```
>>> mask = (a < 3) | (a > 8) | (a == 5)
>>> a[mask] = np.ma.masked
>>> np.array(a[~a.mask])
array([3, 4, 6, 7, 8])
```

```
>>> np.ma.flatnotmasked_contiguous(a)
[slice(3, 5, None), slice(6, 9, None)]
>>> a[:] = np.ma.masked
>>> np.ma.flatnotmasked_contiguous(a)
[]
```

`ma.flatnotmasked_edges(a)`

Find the indices of the first and last unmasked values.

Expects a 1-D *MaskedArray*, returns None if all values are masked.

Parameters

a
[array_like] Input 1-D *MaskedArray*

Returns

edges

[ndarray or None] The indices of first and last non-masked value in the array. Returns None if all values are masked.

See also:

flatnotmasked_contiguous, notmasked_contiguous, notmasked_edges
clump_masked, clump_unmasked

Notes

Only accepts 1-D arrays.

Examples

```
>>> import numpy as np
>>> a = np.ma.arange(10)
>>> np.ma.flatnotmasked_edges(a)
array([0, 9])
```

```
>>> mask = (a < 3) | (a > 8) | (a == 5)
>>> a[mask] = np.ma.masked
>>> np.array(a[~a.mask])
array([3, 4, 6, 7, 8])
```

```
>>> np.ma.flatnotmasked_edges(a)
array([3, 8])
```

```
>>> a[:] = np.ma.masked
>>> print(np.ma.flatnotmasked_edges(a))
None
```

`ma.notmasked_contiguous(a, axis=None)`

Find contiguous unmasked data in a masked array along the given axis.

Parameters

a

[array_like] The input array.

axis

[int, optional] Axis along which to perform the operation. If None (default), applies to a flattened version of the array, and this is the same as *flatnotmasked_contiguous*.

Returns

endpoints

[list] A list of slices (start and end indexes) of unmasked indexes in the array.

If the input is 2d and axis is specified, the result is a list of lists.

See also:

flatnotmasked_edges, flatnotmasked_contiguous, notmasked_edges
clump_masked, clump_unmasked

Notes

Only accepts 2-D arrays at most.

Examples

```
>>> import numpy as np
>>> a = np.arange(12).reshape((3, 4))
>>> mask = np.zeros_like(a)
>>> mask[1:, :-1] = 1; mask[0, 1] = 1; mask[-1, 0] = 0
>>> ma = np.ma.array(a, mask=mask)
>>> ma
masked_array(
  data=[[0, --, 2, 3],
        [--, --, --, 7],
        [8, --, --, 11]],
  mask=[[False,  True, False, False],
        [ True,  True,  True, False],
        [False,  True,  True, False]],
  fill_value=999999)
>>> np.array(ma[~ma.mask])
array([ 0,  2,  3,  7,  8, 11])
```

```
>>> np.ma.notmasked_contiguous(ma)
[slice(0, 1, None), slice(2, 4, None), slice(7, 9, None), slice(11, 12, None)]
```

```
>>> np.ma.notmasked_contiguous(ma, axis=0)
[[slice(0, 1, None), slice(2, 3, None)], [], [slice(0, 1, None)], [slice(0, 3, ↵
↵None)]]
```

```
>>> np.ma.notmasked_contiguous(ma, axis=1)
[[slice(0, 1, None), slice(2, 4, None)], [slice(3, 4, None)], [slice(0, 1, None), ↵
↵slice(3, 4, None)]]
```

`ma.notmasked_edges(a, axis=None)`

Find the indices of the first and last unmasked values along an axis.

If all values are masked, return None. Otherwise, return a list of two tuples, corresponding to the indices of the first and last unmasked values respectively.

Parameters

a

[array_like] The input array.

axis

[int, optional] Axis along which to perform the operation. If None (default), applies to a flattened version of the array.

Returns

edges

[ndarray or list] An array of start and end indexes if there are any masked data in the array. If there are no masked data in the array, *edges* is a list of the first and last index.

See also:

*flatnotmasked_contiguous, flatnotmasked_edges, notmasked_contiguous
clump_masked, clump_unmasked*

Examples

```
>>> import numpy as np
>>> a = np.arange(9).reshape((3, 3))
>>> m = np.zeros_like(a)
>>> m[1:, 1:] = 1
```

```
>>> am = np.ma.array(a, mask=m)
>>> np.array(am[~am.mask])
array([0, 1, 2, 3, 6])
```

```
>>> np.ma.notmasked_edges(am)
array([0, 6])
```

`ma.clump_masked(a)`

Returns a list of slices corresponding to the masked clumps of a 1-D array. (A “clump” is defined as a contiguous region of the array).

Parameters

a
[ndarray] A one-dimensional masked array.

Returns

slices
[list of slice] The list of slices, one for each continuous region of masked elements in *a*.

See also:

*flatnotmasked_edges, flatnotmasked_contiguous, notmasked_edges
notmasked_contiguous, clump_unmasked*

Examples

```
>>> import numpy as np
>>> a = np.ma.masked_array(np.arange(10))
>>> a[[0, 1, 2, 6, 8, 9]] = np.ma.masked
>>> np.ma.clump_masked(a)
[slice(0, 3, None), slice(6, 7, None), slice(8, 10, None)]
```

`ma.clump_unmasked(a)`

Return list of slices corresponding to the unmasked clumps of a 1-D array. (A “clump” is defined as a contiguous region of the array).

Parameters

a
[ndarray] A one-dimensional masked array.

Returns

slices

[list of slice] The list of slices, one for each continuous region of unmasked elements in *a*.

See also:

flatnotmasked_edges, *flatnotmasked_contiguous*, *notmasked_edges*
notmasked_contiguous, *clump_masked*

Examples

```
>>> import numpy as np
>>> a = np.ma.masked_array(np.arange(10))
>>> a[[0, 1, 2, 6, 8, 9]] = np.ma.masked
>>> np.ma.clump_unmasked(a)
[slice(3, 6, None), slice(7, 8, None)]
```

Modifying a mask

<code>ma.mask_cols(a[, axis])</code>	Mask columns of a 2D array that contain masked values.
<code>ma.mask_or(m1, m2[, copy, shrink])</code>	Combine two masks with the <code>logical_or</code> operator.
<code>ma.mask_rowcols(a[, axis])</code>	Mask rows and/or columns of a 2D array that contain masked values.
<code>ma.mask_rows(a[, axis])</code>	Mask rows of a 2D array that contain masked values.
<code>ma.harden_mask(self)</code>	Force the mask to hard, preventing unmasking by assignment.
<code>ma.soften_mask(self)</code>	Force the mask to soft (default), allowing unmasking by assignment.
<code>ma.MaskedArray.harden_mask()</code>	Force the mask to hard, preventing unmasking by assignment.
<code>ma.MaskedArray.soften_mask()</code>	Force the mask to soft (default), allowing unmasking by assignment.
<code>ma.MaskedArray.shrink_mask()</code>	Reduce a mask to nomask when possible.
<code>ma.MaskedArray.unshare_mask()</code>	Copy the mask and set the <i>sharedmask</i> flag to <code>False</code> .

`ma.mask_cols(a, axis=<no value>)`

Mask columns of a 2D array that contain masked values.

This function is a shortcut to `mask_rowcols` with *axis* equal to 1.

See also:

mask_rowcols

Mask rows and/or columns of a 2D array.

masked_where

Mask where a condition is met.

Examples

```
>>> import numpy as np
>>> a = np.zeros((3, 3), dtype=np.int_)
>>> a[1, 1] = 1
>>> a
array([[0, 0, 0],
       [0, 1, 0],
       [0, 0, 0]])
>>> a = np.ma.masked_equal(a, 1)
>>> a
masked_array(
  data=[[0, 0, 0],
        [0, --, 0],
        [0, 0, 0]],
  mask=[[False, False, False],
        [False, True, False],
        [False, False, False]],
  fill_value=1)
>>> np.ma.mask_cols(a)
masked_array(
  data=[[0, --, 0],
        [0, --, 0],
        [0, --, 0]],
  mask=[[False, True, False],
        [False, True, False],
        [False, True, False]],
  fill_value=1)
```

`ma.mask_rowcols(a, axis=None)`

Mask rows and/or columns of a 2D array that contain masked values.

Mask whole rows and/or columns of a 2D array that contain masked values. The masking behavior is selected using the *axis* parameter.

- If *axis* is `None`, rows *and* columns are masked.
- If *axis* is `0`, only rows are masked.
- If *axis* is `1` or `-1`, only columns are masked.

Parameters

a

[array_like, MaskedArray] The array to mask. If not a MaskedArray instance (or if no array elements are masked), the result is a MaskedArray with *mask* set to *nomask* (False). Must be a 2D array.

axis

[int, optional] Axis along which to perform the operation. If `None`, applies to a flattened version of the array.

Returns

a

[MaskedArray] A modified version of the input array, masked depending on the value of the *axis* parameter.

Raises

NotImplementedError

If input array *a* is not 2D.

See also:

mask_rows

Mask rows of a 2D array that contain masked values.

mask_cols

Mask cols of a 2D array that contain masked values.

masked_where

Mask where a condition is met.

Notes

The input array's mask is modified by this function.

Examples

```
>>> import numpy as np
>>> a = np.zeros((3, 3), dtype=np.int_)
>>> a[1, 1] = 1
>>> a
array([[0, 0, 0],
       [0, 1, 0],
       [0, 0, 0]])
>>> a = np.ma.masked_equal(a, 1)
>>> a
masked_array(
  data=[[0, 0, 0],
        [0, --, 0],
        [0, 0, 0]],
  mask=[[False, False, False],
        [False,  True, False],
        [False, False, False]],
  fill_value=1)
>>> np.ma.mask_rowcols(a)
masked_array(
  data=[[0, --, 0],
        [--, --, --],
        [0, --, 0]],
  mask=[[False,  True, False],
        [ True,  True,  True],
        [False,  True, False]],
  fill_value=1)
```

`ma.mask_rows` (*a*, *axis*=<no value>)

Mask rows of a 2D array that contain masked values.

This function is a shortcut to `mask_rowcols` with *axis* equal to 0.

See also:

mask_rowcols

Mask rows and/or columns of a 2D array.

masked_where

Mask where a condition is met.

Examples

```
>>> import numpy as np
>>> a = np.zeros((3, 3), dtype=np.int_)
>>> a[1, 1] = 1
>>> a
array([[0, 0, 0],
       [0, 1, 0],
       [0, 0, 0]])
>>> a = np.ma.masked_equal(a, 1)
>>> a
masked_array(
  data=[[0, 0, 0],
        [0, --, 0],
        [0, 0, 0]],
  mask=[[False, False, False],
        [False,  True, False],
        [False, False, False]],
  fill_value=1)
```

```
>>> np.ma.mask_rows(a)
masked_array(
  data=[[0, 0, 0],
        [--, --, --],
        [0, 0, 0]],
  mask=[[False, False, False],
        [ True,  True,  True],
        [False, False, False]],
  fill_value=1)
```

ma.harden_mask (*self*)

Force the mask to hard, preventing unmasking by assignment.

Whether the mask of a masked array is hard or soft is determined by its *hardmask* property. *harden_mask* sets *hardmask* to True (and returns the modified self).

See also:

ma.MaskedArray.hardmask

ma.MaskedArray.soften_mask

ma.soften_mask (*self*)

Force the mask to soft (default), allowing unmasking by assignment.

Whether the mask of a masked array is hard or soft is determined by its *hardmask* property. *soften_mask* sets *hardmask* to False (and returns the modified self).

See also:

ma.MaskedArray.hardmask

ma.MaskedArray.harden_mask

method

`ma.MaskedArray.harden_mask()`

Force the mask to hard, preventing unmasking by assignment.

Whether the mask of a masked array is hard or soft is determined by its *hardmask* property. *harden_mask* sets *hardmask* to True (and returns the modified self).

See also:

ma.MaskedArray.hardmask

ma.MaskedArray.soften_mask

method

`ma.MaskedArray.soften_mask()`

Force the mask to soft (default), allowing unmasking by assignment.

Whether the mask of a masked array is hard or soft is determined by its *hardmask* property. *soften_mask* sets *hardmask* to False (and returns the modified self).

See also:

ma.MaskedArray.hardmask

ma.MaskedArray.harden_mask

method

`ma.MaskedArray.shrink_mask()`

Reduce a mask to nomask when possible.

Parameters

None

Returns

result

[MaskedArray] A *MaskedArray* object.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[1, 2], [3, 4]], mask=[0]*4)
>>> x.mask
array([[False, False],
       [False, False]])
>>> x.shrink_mask()
masked_array(
  data=[[1, 2],
        [3, 4]],
  mask=False,
  fill_value=999999)
>>> x.mask
False
```

method

`ma.MaskedArray.unshare_mask()`

Copy the mask and set the `sharedmask` flag to `False`.

Whether the mask is shared between masked arrays can be seen from the `sharedmask` property. `unshare_mask` ensures the mask is not shared. A copy of the mask is only made if it was shared.

See also:

`sharedmask`

Conversion operations

> to a masked array

<code>ma.asarray(a[, dtype, order])</code>	Convert the input to a masked array of the given data-type.
<code>ma.asanyarray(a[, dtype, order])</code>	Convert the input to a masked array, conserving sub-classes.
<code>ma.fix_invalid(a[, mask, copy, fill_value])</code>	Return input with invalid data masked and replaced by a fill value.
<code>ma.masked_equal(x, value[, copy])</code>	Mask an array where equal to a given value.
<code>ma.masked_greater(x, value[, copy])</code>	Mask an array where greater than a given value.
<code>ma.masked_greater_equal(x, value[, copy])</code>	Mask an array where greater than or equal to a given value.
<code>ma.masked_inside(x, v1, v2[, copy])</code>	Mask an array inside a given interval.
<code>ma.masked_invalid(a[, copy])</code>	Mask an array where invalid values occur (NaNs or infs).
<code>ma.masked_less(x, value[, copy])</code>	Mask an array where less than a given value.
<code>ma.masked_less_equal(x, value[, copy])</code>	Mask an array where less than or equal to a given value.
<code>ma.masked_not_equal(x, value[, copy])</code>	Mask an array where <i>not</i> equal to a given value.
<code>ma.masked_object(x, value[, copy, shrink])</code>	Mask the array <i>x</i> where the data are exactly equal to value.
<code>ma.masked_outside(x, v1, v2[, copy])</code>	Mask an array outside a given interval.
<code>ma.masked_values(x, value[, rtol, atol, ...])</code>	Mask using floating point equality.
<code>ma.masked_where(condition, a[, copy])</code>	Mask an array where a condition is met.

`ma.asarray(a, dtype=None, order=None)`

Convert the input to a masked array of the given data-type.

No copy is performed if the input is already an `ndarray`. If *a* is a subclass of `MaskedArray`, a base class `MaskedArray` is returned.

Parameters

a

[array_like] Input data, in any form that can be converted to a masked array. This includes lists, lists of tuples, tuples, tuples of tuples, tuples of lists, ndarrays and masked arrays.

dtype

[dtype, optional] By default, the data-type is inferred from the input data.

order

['C', 'F', optional] Whether to use row-major ('C') or column-major ('FORTRAN') memory representation. Default is 'C'.

Returns

out
[MaskedArray] Masked array interpretation of *a*.

See also:

asanyarray

Similar to *asarray*, but conserves subclasses.

Examples

```
>>> import numpy as np
>>> x = np.arange(10.).reshape(2, 5)
>>> x
array([[0., 1., 2., 3., 4.],
       [5., 6., 7., 8., 9.]])
>>> np.ma.asarray(x)
masked_array(
  data=[[0., 1., 2., 3., 4.],
        [5., 6., 7., 8., 9.]],
  mask=False,
  fill_value=1e+20)
>>> type(np.ma.asarray(x))
<class 'numpy.ma.MaskedArray'>
```

`ma.asanyarray` (*a*, *dtype=None*, *order=None*)

Convert the input to a masked array, conserving subclasses.

If *a* is a subclass of *MaskedArray*, its class is conserved. No copy is performed if the input is already an *ndarray*.

Parameters

a
[array_like] Input data, in any form that can be converted to an array.

dtype
[dtype, optional] By default, the data-type is inferred from the input data.

order
[{'C', 'F', 'A', 'K'}, optional] Memory layout. 'A' and 'K' depend on the order of input array
a. 'C' row-major (C-style), 'F' column-major (Fortran-style) memory representation. 'A' (any)
means 'F' if a is Fortran contiguous, 'C' otherwise 'K' (keep) preserve input order Defaults to
'K'.

Returns

out
[MaskedArray] MaskedArray interpretation of *a*.

See also:

asarray

Similar to *asanyarray*, but does not conserve subclass.

Examples

```
>>> import numpy as np
>>> x = np.arange(10.).reshape(2, 5)
>>> x
array([[0., 1., 2., 3., 4.],
       [5., 6., 7., 8., 9.]])
>>> np.ma.asanyarray(x)
masked_array(
  data=[[0., 1., 2., 3., 4.],
        [5., 6., 7., 8., 9.]],
  mask=False,
  fill_value=1e+20)
>>> type(np.ma.asanyarray(x))
<class 'numpy.ma.MaskedArray'>
```

`ma.fix_invalid(a, mask=np.False_, copy=True, fill_value=None)`

Return input with invalid data masked and replaced by a fill value.

Invalid data means values of `nan`, `inf`, etc.

Parameters

a

[array_like] Input array, a (subclass of) ndarray.

mask

[sequence, optional] Mask. Must be convertible to an array of booleans with the same shape as *data*. True indicates a masked (i.e. invalid) data.

copy

[bool, optional] Whether to use a copy of *a* (True) or to fix *a* in place (False). Default is True.

fill_value

[scalar, optional] Value used for fixing invalid data. Default is None, in which case the *a.fill_value* is used.

Returns

b

[MaskedArray] The input array with invalid entries fixed.

Notes

A copy is performed by default.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([1., -1, np.nan, np.inf], mask=[1] + [0]*3)
>>> x
masked_array(data=[--, -1.0, nan, inf],
             mask=[ True, False, False, False],
             fill_value=1e+20)
>>> np.ma.fix_invalid(x)
masked_array(data=[--, -1.0, --, --],
```

(continues on next page)

(continued from previous page)

```
mask=[ True, False,  True,  True],
fill_value=1e+20)
```

```
>>> fixed = np.ma.fix_invalid(x)
>>> fixed.data
array([ 1.e+00, -1.e+00,  1.e+20,  1.e+20])
>>> x.data
array([ 1., -1., nan, inf])
```

`ma.masked_equal` (*x*, *value*, *copy=True*)

Mask an array where equal to a given value.

Return a MaskedArray, masked where the data in array *x* are equal to *value*. The *fill_value* of the returned MaskedArray is set to *value*.

For floating point arrays, consider using `masked_values` (*x*, *value*).

See also:

[`masked\_where`](#)

Mask where a condition is met.

[`masked\_values`](#)

Mask using floating point equality.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.arange(4)
>>> a
array([0, 1, 2, 3])
>>> ma.masked_equal(a, 2)
masked_array(data=[0, 1, --, 3],
             mask=[False, False,  True, False],
             fill_value=2)
```

`ma.masked_greater` (*x*, *value*, *copy=True*)

Mask an array where greater than a given value.

This function is a shortcut to `masked_where`, with *condition* = (*x* > *value*).

See also:

[`masked\_where`](#)

Mask where a condition is met.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.arange(4)
>>> a
array([0, 1, 2, 3])
>>> ma.masked_greater(a, 2)
masked_array(data=[0, 1, 2, --],
             mask=[False, False, False,  True],
             fill_value=999999)
```

`ma.masked_greater_equal(x, value, copy=True)`

Mask an array where greater than or equal to a given value.

This function is a shortcut to `masked_where`, with *condition* = $(x \geq \text{value})$.

See also:

[*masked_where*](#)

Mask where a condition is met.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.arange(4)
>>> a
array([0, 1, 2, 3])
>>> ma.masked_greater_equal(a, 2)
masked_array(data=[0, 1, --, --],
             mask=[False, False,  True,  True],
             fill_value=999999)
```

`ma.masked_inside(x, v1, v2, copy=True)`

Mask an array inside a given interval.

Shortcut to `masked_where`, where *condition* is True for x inside the interval $[v1, v2]$ ($v1 \leq x \leq v2$). The boundaries $v1$ and $v2$ can be given in either order.

See also:

[*masked_where*](#)

Mask where a condition is met.

Notes

The array x is prefilled with its filling value.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = [0.31, 1.2, 0.01, 0.2, -0.4, -1.1]
>>> ma.masked_inside(x, -0.3, 0.3)
masked_array(data=[0.31, 1.2, --, --, -0.4, -1.1],
             mask=[False, False,  True,  True, False, False],
             fill_value=1e+20)
```

The order of *v1* and *v2* doesn't matter.

```
>>> ma.masked_inside(x, 0.3, -0.3)
masked_array(data=[0.31, 1.2, --, --, -0.4, -1.1],
             mask=[False, False,  True,  True, False, False],
             fill_value=1e+20)
```

`ma.masked_invalid(a, copy=True)`

Mask an array where invalid values occur (NaNs or infs).

This function is a shortcut to `masked_where`, with *condition* = `~(np.isfinite(a))`. Any pre-existing mask is conserved. Only applies to arrays with a dtype where NaNs or infs make sense (i.e. floating point types), but accepts any array_like object.

See also:

[*masked_where*](#)

Mask where a condition is met.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.arange(5, dtype=np.float64)
>>> a[2] = np.nan
>>> a[3] = np.inf
>>> a
array([ 0.,  1., nan, inf,  4.])
>>> ma.masked_invalid(a)
masked_array(data=[0.0, 1.0, --, --, 4.0],
             mask=[False, False,  True,  True, False],
             fill_value=1e+20)
```

`ma.masked_less(x, value, copy=True)`

Mask an array where less than a given value.

This function is a shortcut to `masked_where`, with *condition* = `(x < value)`.

See also:

[*masked_where*](#)

Mask where a condition is met.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.arange(4)
>>> a
array([0, 1, 2, 3])
>>> ma.masked_less(a, 2)
masked_array(data=[--, --, 2, 3],
             mask=[ True,  True, False, False],
             fill_value=999999)
```

`ma.masked_less_equal(x, value, copy=True)`

Mask an array where less than or equal to a given value.

This function is a shortcut to `masked_where`, with *condition* = (x <= value).

See also:

[*masked_where*](#)

Mask where a condition is met.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.arange(4)
>>> a
array([0, 1, 2, 3])
>>> ma.masked_less_equal(a, 2)
masked_array(data=[--, --, --, 3],
             mask=[ True,  True,  True, False],
             fill_value=999999)
```

`ma.masked_not_equal(x, value, copy=True)`

Mask an array where *not* equal to a given value.

This function is a shortcut to `masked_where`, with *condition* = (x != value).

See also:

[*masked_where*](#)

Mask where a condition is met.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.arange(4)
>>> a
array([0, 1, 2, 3])
>>> ma.masked_not_equal(a, 2)
masked_array(data=[--, --, 2, --],
             mask=[ True,  True, False,  True],
             fill_value=999999)
```

`ma.masked_object` (*x*, *value*, *copy=True*, *shrink=True*)

Mask the array *x* where the data are exactly equal to *value*.

This function is similar to `masked_values`, but only suitable for object arrays: for floating point, use `masked_values` instead.

Parameters

x

[array_like] Array to mask

value

[object] Comparison value

copy

[{True, False}, optional] Whether to return a copy of *x*.

shrink

[{True, False}, optional] Whether to collapse a mask full of False to nomask

Returns

result

[MaskedArray] The result of masking *x* where equal to *value*.

See also:

`masked_where`

Mask where a condition is met.

`masked_equal`

Mask where equal to a given value (integers).

`masked_values`

Mask using floating point equality.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> food = np.array(['green_eggs', 'ham'], dtype=np.object_)
>>> # don't eat spoiled food
>>> eat = ma.masked_object(food, 'green_eggs')
>>> eat
masked_array(data=[--, 'ham'],
              mask=[ True, False],
              fill_value='green_eggs',
              dtype=object)
>>> # plain ol' ham is boring
>>> fresh_food = np.array(['cheese', 'ham', 'pineapple'], dtype=np.object_)
>>> eat = ma.masked_object(fresh_food, 'green_eggs')
>>> eat
masked_array(data=['cheese', 'ham', 'pineapple'],
              mask=False,
              fill_value='green_eggs',
              dtype=object)
```

Note that *mask* is set to nomask if possible.

```
>>> eat
masked_array(data=['cheese', 'ham', 'pineapple'],
             mask=False,
             fill_value='green_eggs',
             dtype=object)
```

`ma.masked_outside(x, v1, v2, copy=True)`

Mask an array outside a given interval.

Shortcut to `masked_where`, where *condition* is True for *x* outside the interval [*v1*,*v2*] ($x < v1$)($x > v2$). The boundaries *v1* and *v2* can be given in either order.

See also:

[*masked_where*](#)

Mask where a condition is met.

Notes

The array *x* is prefilled with its filling value.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = [0.31, 1.2, 0.01, 0.2, -0.4, -1.1]
>>> ma.masked_outside(x, -0.3, 0.3)
masked_array(data=[--, --, 0.01, 0.2, --, --],
             mask=[ True,  True, False, False,  True,  True],
             fill_value=1e+20)
```

The order of *v1* and *v2* doesn't matter.

```
>>> ma.masked_outside(x, 0.3, -0.3)
masked_array(data=[--, --, 0.01, 0.2, --, --],
             mask=[ True,  True, False, False,  True,  True],
             fill_value=1e+20)
```

`ma.masked_values(x, value, rtol=1e-05, atol=1e-08, copy=True, shrink=True)`

Mask using floating point equality.

Return a MaskedArray, masked where the data in array *x* are approximately equal to *value*, determined using [*isclose*](#). The default tolerances for [*masked_values*](#) are the same as those for [*isclose*](#).

For integer types, exact equality is used, in the same way as [*masked_equal*](#).

The *fill_value* is set to *value* and the mask is set to *nomask* if possible.

Parameters

x
[array_like] Array to mask.

value
[float] Masking value.

rtol, atol

[float, optional] Tolerance parameters passed on to *isclose*

copy

[bool, optional] Whether to return a copy of *x*.

shrink

[bool, optional] Whether to collapse a mask full of False to *nomask*.

Returns**result**

[MaskedArray] The result of masking *x* where approximately equal to *value*.

See also:*masked_where*

Mask where a condition is met.

masked_equal

Mask where equal to a given value (integers).

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = np.array([1, 1.1, 2, 1.1, 3])
>>> ma.masked_values(x, 1.1)
masked_array(data=[1.0, --, 2.0, --, 3.0],
             mask=[False,  True, False,  True, False],
             fill_value=1.1)
```

Note that *mask* is set to *nomask* if possible.

```
>>> ma.masked_values(x, 2.1)
masked_array(data=[1. , 1.1, 2. , 1.1, 3. ],
             mask=False,
             fill_value=2.1)
```

Unlike *masked_equal*, *masked_values* can perform approximate equalities.

```
>>> ma.masked_values(x, 2.1, atol=1e-1)
masked_array(data=[1.0, 1.1, --, 1.1, 3.0],
             mask=[False, False,  True, False, False],
             fill_value=2.1)
```

`ma.masked_where` (*condition*, *a*, *copy=True*)

Mask an array where a condition is met.

Return *a* as an array masked where *condition* is True. Any masked values of *a* or *condition* are also masked in the output.

Parameters**condition**

[array_like] Masking condition. When *condition* tests floating point values for equality, consider using *masked_values* instead.

a
[array_like] Array to mask.

copy
[bool] If True (default) make a copy of *a* in the result. If False modify *a* in place and return a view.

Returns

result
[MaskedArray] The result of masking *a* where *condition* is True.

See also:

masked_values

Mask using floating point equality.

masked_equal

Mask where equal to a given value.

masked_not_equal

Mask where *not* equal to a given value.

masked_less_equal

Mask where less than or equal to a given value.

masked_greater_equal

Mask where greater than or equal to a given value.

masked_less

Mask where less than a given value.

masked_greater

Mask where greater than a given value.

masked_inside

Mask inside a given interval.

masked_outside

Mask outside a given interval.

masked_invalid

Mask invalid values (NaNs or infs).

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.arange(4)
>>> a
array([0, 1, 2, 3])
>>> ma.masked_where(a <= 2, a)
masked_array(data=[--, --, --, 3],
             mask=[ True,  True,  True, False],
             fill_value=999999)
```

Mask array *b* conditional on *a*.

```
>>> b = ['a', 'b', 'c', 'd']
>>> ma.masked_where(a == 2, b)
masked_array(data=['a', 'b', '--, 'd'],
             mask=[False, False,  True, False],
             fill_value='N/A',
             dtype='<U1')
```

Effect of the `copy` argument.

```
>>> c = ma.masked_where(a <= 2, a)
>>> c
masked_array(data=[--, --, --, 3],
             mask=[ True,  True,  True, False],
             fill_value=999999)
>>> c[0] = 99
>>> c
masked_array(data=[99, --, --, 3],
             mask=[False,  True,  True, False],
             fill_value=999999)
>>> a
array([0, 1, 2, 3])
>>> c = ma.masked_where(a <= 2, a, copy=False)
>>> c[0] = 99
>>> c
masked_array(data=[99, --, --, 3],
             mask=[False,  True,  True, False],
             fill_value=999999)
>>> a
array([99,  1,  2,  3])
```

When *condition* or *a* contain masked values.

```
>>> a = np.arange(4)
>>> a = ma.masked_where(a == 2, a)
>>> a
masked_array(data=[0, 1, --, 3],
             mask=[False, False,  True, False],
             fill_value=999999)
>>> b = np.arange(4)
>>> b = ma.masked_where(b == 0, b)
>>> b
masked_array(data=[--, 1, 2, 3],
             mask=[ True, False, False, False],
             fill_value=999999)
>>> ma.masked_where(a == 3, b)
masked_array(data=[--, 1, --, --],
             mask=[ True, False,  True,  True],
             fill_value=999999)
```

> to an ndarray

<code>ma.compress_cols(a)</code>	Suppress whole columns of a 2-D array that contain masked values.
<code>ma.compress_rowcols(x[, axis])</code>	Suppress the rows and/or columns of a 2-D array that contain masked values.
<code>ma.compress_rows(a)</code>	Suppress whole rows of a 2-D array that contain masked values.
<code>ma.compressed(x)</code>	Return all the non-masked data as a 1-D array.
<code>ma.filled(a[, fill_value])</code>	Return input as an <i>ndarray</i> , with masked values replaced by <i>fill_value</i> .
<code>ma.MaskedArray.compressed()</code>	Return all the non-masked data as a 1-D array.
<code>ma.MaskedArray.filled([fill_value])</code>	Return a copy of self, with masked values filled with a given value.

`ma.compress_cols(a)`

Suppress whole columns of a 2-D array that contain masked values.

This is equivalent to `np.ma.compress_rowcols(a, 1)`, see *compress_rowcols* for details.

Parameters

x

[array_like, MaskedArray] The array to operate on. If not a MaskedArray instance (or if no array elements are masked), *x* is interpreted as a MaskedArray with *mask* set to *nomask*. Must be a 2D array.

Returns

compressed_array

[ndarray] The compressed array.

See also:

compress_rowcols

Examples

```
>>> import numpy as np
>>> a = np.ma.array(np.arange(9).reshape(3, 3), mask=[[1, 0, 0],
...                                                  [1, 0, 0],
...                                                  [0, 0, 0]])
>>> np.ma.compress_cols(a)
array([[1, 2],
       [4, 5],
       [7, 8]])
```

`ma.compress_rowcols(x, axis=None)`

Suppress the rows and/or columns of a 2-D array that contain masked values.

The suppression behavior is selected with the *axis* parameter.

- If *axis* is None, both rows and columns are suppressed.
- If *axis* is 0, only rows are suppressed.

- If axis is 1 or -1, only columns are suppressed.

Parameters**x**

[array_like, MaskedArray] The array to operate on. If not a MaskedArray instance (or if no array elements are masked), *x* is interpreted as a MaskedArray with *mask* set to *nomask*. Must be a 2D array.

axis

[int, optional] Axis along which to perform the operation. Default is None.

Returns**compressed_array**

[ndarray] The compressed array.

Examples

```
>>> import numpy as np
>>> x = np.ma.array(np.arange(9).reshape(3, 3), mask=[[1, 0, 0],
...                                                  [1, 0, 0],
...                                                  [0, 0, 0]])
>>> x
masked_array(
  data=[[-, 1, 2],
        [-, 4, 5],
        [6, 7, 8]],
  mask=[[ True, False, False],
        [ True, False, False],
        [False, False, False]],
  fill_value=999999)
```

```
>>> np.ma.compress_rowcols(x)
array([[7, 8]])
>>> np.ma.compress_rowcols(x, 0)
array([[6, 7, 8]])
>>> np.ma.compress_rowcols(x, 1)
array([[1, 2],
       [4, 5],
       [7, 8]])
```

`ma.compress_rows(a)`

Suppress whole rows of a 2-D array that contain masked values.

This is equivalent to `np.ma.compress_rowcols(a, 0)`, see [compress_rowcols](#) for details.

Parameters**x**

[array_like, MaskedArray] The array to operate on. If not a MaskedArray instance (or if no array elements are masked), *x* is interpreted as a MaskedArray with *mask* set to *nomask*. Must be a 2D array.

Returns**compressed_array**

[ndarray] The compressed array.

See also:

[`compress\_rowcols`](#)

Examples

```
>>> import numpy as np
>>> a = np.ma.array(np.arange(9).reshape(3, 3), mask=[[1, 0, 0],
...                                                  [1, 0, 0],
...                                                  [0, 0, 0]])
>>> np.ma.compress_rows(a)
array([[6, 7, 8]])
```

`ma.compressed(x)`

Return all the non-masked data as a 1-D array.

This function is equivalent to calling the “compressed” method of a [`ma.MaskedArray`](#), see [`ma.MaskedArray.compressed`](#) for details.

See also:

[`ma.MaskedArray.compressed`](#)

Equivalent method.

Examples

```
>>> import numpy as np
```

Create an array with negative values masked:

```
>>> import numpy as np
>>> x = np.array([[1, -1, 0], [2, -1, 3], [7, 4, -1]])
>>> masked_x = np.ma.masked_array(x, mask=x < 0)
>>> masked_x
masked_array(
  data=[[1, --, 0],
        [2, --, 3],
        [7, 4, --]],
  mask=[[False,  True, False],
        [False,  True, False],
        [False, False,  True]],
  fill_value=999999)
```

Compress the masked array into a 1-D array of non-masked values:

```
>>> np.ma.compressed(masked_x)
array([1, 0, 2, 3, 7, 4])
```

`ma.filled(a, fill_value=None)`

Return input as an [`ndarray`](#), with masked values replaced by `fill_value`.

If `a` is not a [`MaskedArray`](#), `a` itself is returned. If `a` is a [`MaskedArray`](#) with no masked values, then `a.data` is returned. If `a` is a [`MaskedArray`](#) and `fill_value` is `None`, `fill_value` is set to `a.fill_value`.

Parameters

a
[MaskedArray or array_like] An input object.

fill_value
[array_like, optional.] Can be scalar or non-scalar. If non-scalar, the resulting filled array should be broadcastable over input array. Default is None.

Returns

a
[ndarray] The filled array.

See also:

compressed

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = ma.array(np.arange(9).reshape(3, 3), mask=[[1, 0, 0],
...                                               [1, 0, 0],
...                                               [0, 0, 0]])
>>> x.filled()
array([[999999,      1,      2],
       [999999,      4,      5],
       [      6,      7,      8]])
>>> x.filled(fill_value=333)
array([[333,      1,      2],
       [333,      4,      5],
       [   6,      7,      8]])
>>> x.filled(fill_value=np.arange(3))
array([[0, 1, 2],
       [0, 4, 5],
       [6, 7, 8]])
```

method

`ma.MaskedArray.compressed()`

Return all the non-masked data as a 1-D array.

Returns

data
[ndarray] A new *ndarray* holding the non-masked data is returned.

Notes

The result is **not** a MaskedArray!

Examples

```
>>> import numpy as np
>>> x = np.ma.array(np.arange(5), mask=[0]*2 + [1]*3)
>>> x.compressed()
array([0, 1])
>>> type(x.compressed())
<class 'numpy.ndarray'>
```

N-D arrays are compressed to 1-D.

```
>>> arr = [[1, 2], [3, 4]]
>>> mask = [[1, 0], [0, 1]]
>>> x = np.ma.array(arr, mask=mask)
>>> x.compressed()
array([2, 3])
```

method

`ma.MaskedArray.filled(fill_value=None)`

Return a copy of self, with masked values filled with a given value. **However**, if there are no masked values to fill, self will be returned instead as an ndarray.

Parameters

`fill_value`

[array_like, optional] The value to use for invalid entries. Can be scalar or non-scalar. If non-scalar, the resulting ndarray must be broadcastable over input array. Default is None, in which case, the `fill_value` attribute of the array is used instead.

Returns

`filled_array`

[ndarray] A copy of self with invalid entries replaced by `fill_value` (be it the function argument or the attribute of self), or self itself as an ndarray if there are no invalid entries to be replaced.

Notes

The result is **not** a MaskedArray!

Examples

```
>>> import numpy as np
>>> x = np.ma.array([1,2,3,4,5], mask=[0,0,1,0,1], fill_value=-999)
>>> x.filled()
array([ 1,  2, -999,  4, -999])
>>> x.filled(fill_value=1000)
array([ 1,  2, 1000,  4, 1000])
>>> type(x.filled())
<class 'numpy.ndarray'>
```

Subclassing is preserved. This means that if, e.g., the data part of the masked array is a recarray, `filled` returns a recarray:

```
>>> x = np.array([(-1, 2), (-3, 4)], dtype='i8,i8').view(np.recarray)
>>> m = np.ma.array(x, mask=[(True, False), (False, True)])
>>> m.filled()
rec.array([(9999999,      2), (      -3, 9999999)],
          dtype=[('f0', '<i8'), ('f1', '<i8')])
```

> to another object

<code>ma.MaskedArray.tofile(fid[, sep, format])</code>	Save a masked array to a file in binary format.
<code>ma.MaskedArray.tolist([fill_value])</code>	Return the data portion of the masked array as a hierarchical Python list.
<code>ma.MaskedArray.torecords()</code>	Transforms a masked array into a flexible-type array.
<code>ma.MaskedArray.tobytes([fill_value, order])</code>	Return the array data as a string containing the raw bytes in the array.

method

`ma.MaskedArray.tofile (fid, sep="", format='%s')`

Save a masked array to a file in binary format.

Warning: This function is not implemented yet.

Raises

NotImplementedError

When `tofile` is called.

method

`ma.MaskedArray.tolist (fill_value=None)`

Return the data portion of the masked array as a hierarchical Python list.

Data items are converted to the nearest compatible Python type. Masked values are converted to `fill_value`. If `fill_value` is `None`, the corresponding entries in the output list will be `None`.

Parameters

fill_value

[scalar, optional] The value to use for invalid entries. Default is `None`.

Returns

result

[list] The Python list representation of the masked array.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[1,2,3], [4,5,6], [7,8,9]], mask=[0] + [1,0]*4)
>>> x.tolist()
[[1, None, 3], [None, 5, None], [7, None, 9]]
>>> x.tolist(-999)
[[1, -999, 3], [-999, 5, -999], [7, -999, 9]]
```

method

`ma.MaskedArray.torecords()`

Transforms a masked array into a flexible-type array.

The flexible type array that is returned will have two fields:

- the `_data` field stores the `_data` part of the array.
- the `_mask` field stores the `_mask` part of the array.

Parameters

None

Returns

record

[ndarray] A new flexible-type `ndarray` with two fields: the first element containing a value, the second element containing the corresponding mask boolean. The returned record shape matches `self.shape`.

Notes

A side-effect of transforming a masked array into a flexible `ndarray` is that meta information (`fill_value`, ...) will be lost.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[1,2,3], [4,5,6], [7,8,9]], mask=[0] + [1,0]*4)
>>> x
masked_array(
  data=[[1, --, 3],
        [--, 5, --],
        [7, --, 9]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=999999)
>>> x.toflex()
array([(1, False), (2,  True), (3, False)],
      [(4,  True), (5, False), (6,  True)],
      [(7, False), (8,  True), (9, False)]],
      dtype=[('_data', '<i8'), ('_mask', '?')])
```

method

`ma.MaskedArray.tobytes` (*fill_value=None, order='C'*)

Return the array data as a string containing the raw bytes in the array.

The array is filled with a fill value before the string conversion.

Parameters

fill_value

[scalar, optional] Value used to fill in the masked values. Default is None, in which case `MaskedArray.fill_value` is used.

order

[{'C','F','A'}, optional] Order of the data item in the copy. Default is 'C'.

- 'C' – C order (row major).
- 'F' – Fortran order (column major).
- 'A' – Any, current order of array.
- None – Same as 'A'.

See also:

`numpy.ndarray.tobytes`
`tolist, tofile`

Notes

As for `ndarray.tobytes`, information about the shape, dtype, etc., but also about `fill_value`, will be lost.

Examples

```
>>> import numpy as np
>>> x = np.ma.array(np.array([[1, 2], [3, 4]]), mask=[[0, 1], [1, 0]])
>>> x.tobytes()
b'\x01\x00\x00\x00\x00\x00\x00\x00?B\x0f\x00\x00\x00\x00\x00?B\x0f\x00\x00\x00\x00\x00\x04\x00\x00\x00\x00\x00\x00'
```

Filling a masked array

<code>ma.common_fill_value(a, b)</code>	Return the common filling value of two masked arrays, if any.
<code>ma.default_fill_value(obj)</code>	Return the default fill value for the argument object.
<code>ma.maximum_fill_value(obj)</code>	Return the minimum value that can be represented by the dtype of an object.
<code>ma.minimum_fill_value(obj)</code>	Return the maximum value that can be represented by the dtype of an object.
<code>ma.set_fill_value(a, fill_value)</code>	Set the filling value of a, if a is a masked array.
<code>ma.MaskedArray.get_fill_value()</code>	The filling value of the masked array is a scalar.
<code>ma.MaskedArray.set_fill_value([value])</code>	

`ma.common_fill_value(a, b)`

Return the common filling value of two masked arrays, if any.

If `a.fill_value == b.fill_value`, return the fill value, otherwise return `None`.

Parameters

a, b

[MaskedArray] The masked arrays for which to compare fill values.

Returns

fill_value

[scalar or None] The common fill value, or `None`.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([0, 1.], fill_value=3)
>>> y = np.ma.array([0, 1.], fill_value=3)
>>> np.ma.common_fill_value(x, y)
3.0
```

`ma.default_fill_value(obj)`

Return the default fill value for the argument object.

The default filling value depends on the datatype of the input array or the type of the input scalar:

datatype	default
bool	True
int	999999
float	1.e20
complex	1.e20+0j
object	'?'
string	'N/A'
StringDType	'N/A'

For structured types, a structured scalar is returned, with each field the default fill value for its type.

For subarray types, the fill value is an array of the same size containing the default scalar fill value.

Parameters

obj

[ndarray, dtype or scalar] The array data-type or scalar for which the default fill value is returned.

Returns

fill_value

[scalar] The default fill value.

Examples

```
>>> import numpy as np
>>> np.ma.default_fill_value(1)
999999
>>> np.ma.default_fill_value(np.array([1.1, 2., np.pi]))
1e+20
>>> np.ma.default_fill_value(np.dtype(complex))
(1e+20+0j)
```

`ma.maximum_fill_value(obj)`

Return the minimum value that can be represented by the dtype of an object.

This function is useful for calculating a fill value suitable for taking the maximum of an array with a given dtype.

Parameters

obj

[ndarray, dtype or scalar] An object that can be queried for its numeric type.

Returns

val

[scalar] The minimum representable value.

Raises

TypeError

If *obj* isn't a suitable numeric type.

See also:

minimum_fill_value

The inverse function.

set_fill_value

Set the filling value of a masked array.

MaskedArray.fill_value

Return current fill value.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.int8()
>>> ma.maximum_fill_value(a)
-128
>>> a = np.int32()
>>> ma.maximum_fill_value(a)
-2147483648
```

An array of numeric data can also be passed.

```
>>> a = np.array([1, 2, 3], dtype=np.int8)
>>> ma.maximum_fill_value(a)
-128
>>> a = np.array([1, 2, 3], dtype=np.float32)
```

(continues on next page)

(continued from previous page)

```
>>> ma.minimum_fill_value(a)
-inf
```

`ma.minimum_fill_value(obj)`

Return the maximum value that can be represented by the dtype of an object.

This function is useful for calculating a fill value suitable for taking the minimum of an array with a given dtype.

Parameters

obj

[ndarray, dtype or scalar] An object that can be queried for its numeric type.

Returns

val

[scalar] The maximum representable value.

Raises

TypeError

If *obj* isn't a suitable numeric type.

See also:

[`maximum\_fill\_value`](#)

The inverse function.

[`set\_fill\_value`](#)

Set the filling value of a masked array.

[`MaskedArray.fill\_value`](#)

Return current fill value.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.int8()
>>> ma.minimum_fill_value(a)
127
>>> a = np.int32()
>>> ma.minimum_fill_value(a)
2147483647
```

An array of numeric data can also be passed.

```
>>> a = np.array([1, 2, 3], dtype=np.int8)
>>> ma.minimum_fill_value(a)
127
>>> a = np.array([1, 2, 3], dtype=np.float32)
>>> ma.minimum_fill_value(a)
inf
```

`ma.set_fill_value(a, fill_value)`

Set the filling value of a, if a is a masked array.

This function changes the fill value of the masked array *a* in place. If *a* is not a masked array, the function returns silently, without doing anything.

Parameters

- a**
[array_like] Input array.
- fill_value**
[dtype] Filling value. A consistency test is performed to make sure the value is compatible with the dtype of *a*.

Returns

- None**
Nothing returned by this function.

See also:***maximum_fill_value***

Return the default fill value for a dtype.

MaskedArray.fill_value

Return current fill value.

MaskedArray.set_fill_value

Equivalent method.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> a = np.arange(5)
>>> a
array([0, 1, 2, 3, 4])
>>> a = ma.masked_where(a < 3, a)
>>> a
masked_array(data=[--, --, --, 3, 4],
             mask=[ True,  True,  True, False, False],
             fill_value=999999)
>>> ma.set_fill_value(a, -999)
>>> a
masked_array(data=[--, --, --, 3, 4],
             mask=[ True,  True,  True, False, False],
             fill_value=-999)
```

Nothing happens if *a* is not a masked array.

```
>>> a = list(range(5))
>>> a
[0, 1, 2, 3, 4]
>>> ma.set_fill_value(a, 100)
>>> a
[0, 1, 2, 3, 4]
>>> a = np.arange(5)
>>> a
array([0, 1, 2, 3, 4])
>>> ma.set_fill_value(a, 100)
```

(continues on next page)

(continued from previous page)

```
>>> a
array([0, 1, 2, 3, 4])
```

method

`ma.MaskedArray.get_fill_value()`

The filling value of the masked array is a scalar. When setting, None will set to a default based on the data type.

Examples

```
>>> import numpy as np
>>> for dt in [np.int32, np.int64, np.float64, np.complex128]:
...     np.ma.array([0, 1], dtype=dt).get_fill_value()
...
np.int64(9999999)
np.int64(9999999)
np.float64(1e+20)
np.complex128(1e+20+0j)
```

```
>>> x = np.ma.array([0, 1.], fill_value=-np.inf)
>>> x.fill_value
np.float64(-inf)
>>> x.fill_value = np.pi
>>> x.fill_value
np.float64(3.1415926535897931)
```

Reset to default:

```
>>> x.fill_value = None
>>> x.fill_value
np.float64(1e+20)
```

method

`ma.MaskedArray.set_fill_value(value=None)`

ma.MaskedArray.fill_value

The filling value of the masked array is a scalar.

Masked arrays arithmetic

Arithmetic

<code>ma.anom(self[, axis, dtype])</code>	Compute the anomalies (deviations from the arithmetic mean) along the given axis.
<code>ma.anomalies(self[, axis, dtype])</code>	Compute the anomalies (deviations from the arithmetic mean) along the given axis.
<code>ma.average(a[, axis, weights, returned, ...])</code>	Return the weighted average of array over the given axis.
<code>ma.conjugate(x, /[, out, where, casting, ...])</code>	Return the complex conjugate, element-wise.
<code>ma.corrcoef(x[, y, rowvar, allow_masked])</code>	Return Pearson product-moment correlation coefficients.
<code>ma.cov(x[, y, rowvar, bias, allow_masked, ddof])</code>	Estimate the covariance matrix.
<code>ma.cumsum(self[, axis, dtype, out])</code>	Return the cumulative sum of the array elements over the given axis.
<code>ma.cumprod(self[, axis, dtype, out])</code>	Return the cumulative product of the array elements over the given axis.
<code>ma.mean(self[, axis, dtype, out, keepdims])</code>	Returns the average of the array elements along given axis.
<code>ma.median(a[, axis, out, overwrite_input, ...])</code>	Compute the median along the specified axis.
<code>ma.power(a, b[, third])</code>	Returns element-wise base array raised to power from second array.
<code>ma.prod(self[, axis, dtype, out, keepdims])</code>	Return the product of the array elements over the given axis.
<code>ma.std(self[, axis, dtype, out, ddof, ...])</code>	Returns the standard deviation of the array elements along given axis.
<code>ma.sum(self[, axis, dtype, out, keepdims])</code>	Return the sum of the array elements over the given axis.
<code>ma.var(self[, axis, dtype, out, ddof, ...])</code>	Compute the variance along the specified axis.
<code>ma.MaskedArray.anom([axis, dtype])</code>	Compute the anomalies (deviations from the arithmetic mean) along the given axis.
<code>ma.MaskedArray.cumprod([axis, dtype, out])</code>	Return the cumulative product of the array elements over the given axis.
<code>ma.MaskedArray.cumsum([axis, dtype, out])</code>	Return the cumulative sum of the array elements over the given axis.
<code>ma.MaskedArray.mean([axis, dtype, out, keepdims])</code>	Returns the average of the array elements along given axis.
<code>ma.MaskedArray.prod([axis, dtype, out, keepdims])</code>	Return the product of the array elements over the given axis.
<code>ma.MaskedArray.std([axis, dtype, out, ddof, ...])</code>	Returns the standard deviation of the array elements along given axis.
<code>ma.MaskedArray.sum([axis, dtype, out, keepdims])</code>	Return the sum of the array elements over the given axis.
<code>ma.MaskedArray.var([axis, dtype, out, ddof, ...])</code>	Compute the variance along the specified axis.

`ma.anom(self, axis=None, dtype=None)`

Compute the anomalies (deviations from the arithmetic mean) along the given axis.

Returns an array of anomalies, with the same shape as the input and where the arithmetic mean is computed along the given axis.

Parameters**axis**

[int, optional] Axis over which the anomalies are taken. The default is to use the mean of the flattened array as reference.

dtype

[dtype, optional] Type to use in computing the variance. For arrays of integer type the default is float32; for arrays of float types it is the same as the array type.

See also:

[*mean*](#)

Compute the mean of the array.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([1,2,3])
>>> a.anom()
masked_array(data=[-1.,  0.,  1.],
              mask=False,
              fill_value=1e+20)
```

ma.anomalies (*self*, *axis=None*, *dtype=None*)

Compute the anomalies (deviations from the arithmetic mean) along the given axis.

Returns an array of anomalies, with the same shape as the input and where the arithmetic mean is computed along the given axis.

Parameters

axis

[int, optional] Axis over which the anomalies are taken. The default is to use the mean of the flattened array as reference.

dtype

[dtype, optional] Type to use in computing the variance. For arrays of integer type the default is float32; for arrays of float types it is the same as the array type.

See also:

[*mean*](#)

Compute the mean of the array.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([1,2,3])
>>> a.anom()
masked_array(data=[-1.,  0.,  1.],
              mask=False,
              fill_value=1e+20)
```

ma.average (*a*, *axis=None*, *weights=None*, *returned=False*, *, *keepdims=<no value>*)

Return the weighted average of array over the given axis.

Parameters

a

[array_like] Data to be averaged. Masked entries are not taken into account in the computation.

axis

[None or int or tuple of ints, optional] Axis or axes along which to average *a*. The default, *axis=None*, will average over all of the elements of the input array. If *axis* is a tuple of ints, averaging is performed on all of the axes specified in the tuple instead of a single axis or all the axes as before.

weights

[array_like, optional] An array of weights associated with the values in *a*. Each value in *a* contributes to the average according to its associated weight. The array of weights must be the same shape as *a* if no axis is specified, otherwise the weights must have dimensions and shape consistent with *a* along the specified axis. If *weights=None*, then all data in *a* are assumed to have a weight equal to one. The calculation is:

```
avg = sum(a * weights) / sum(weights)
```

where the sum is over all included elements. The only constraint on the values of *weights* is that *sum(weights)* must not be 0.

returned

[bool, optional] Flag indicating whether a tuple (*result*, *sum of weights*) should be returned as output (True), or just the result (False). Default is False.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *a*. *Note: keepdims* will not work with instances of *numpy.matrix* or other classes whose methods do not support *keepdims*.

New in version 1.23.0.

Returns**average, [sum_of_weights]**

[(tuple of) scalar or MaskedArray] The average along the specified axis. When returned is *True*, return a tuple with the average as the first element and the sum of the weights as the second element. The return type is *np.float64* if *a* is of integer type and floats smaller than *float64*, or the input data-type, otherwise. If returned, *sum_of_weights* is always *float64*.

Raises**ZeroDivisionError**

When all weights along axis are zero. See *numpy.ma.average* for a version robust to this type of error.

TypeError

When *weights* does not have the same shape as *a*, and *axis=None*.

ValueError

When *weights* does not have dimensions and shape consistent with *a* along specified *axis*.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([1., 2., 3., 4.], mask=[False, False, True, True])
>>> np.ma.average(a, weights=[3, 1, 0, 0])
1.25
```

```
>>> x = np.ma.arange(6.).reshape(3, 2)
>>> x
masked_array(
  data=[[0., 1.],
        [2., 3.]
```

(continues on next page)

(continued from previous page)

```

    [4., 5.]],
    mask=False,
    fill_value=1e+20)
>>> data = np.arange(8).reshape((2, 2, 2))
>>> data
array([[[0, 1],
        [2, 3]],
       [[4, 5],
        [6, 7]]])
>>> np.ma.average(data, axis=(0, 1), weights=[[1./4, 3./4], [1., 1./2]])
masked_array(data=[3.4, 4.4],
             mask=[False, False],
             fill_value=1e+20)
>>> np.ma.average(data, axis=0, weights=[[1./4, 3./4], [1., 1./2]])
Traceback (most recent call last):
...
ValueError: Shape of weights must be consistent
with shape of a along specified axis.

```

```

>>> avg, sumweights = np.ma.average(x, axis=0, weights=[1, 2, 3],
...                               returned=True)
>>> avg
masked_array(data=[2.6666666666666665, 3.6666666666666665],
             mask=[False, False],
             fill_value=1e+20)

```

With `keepdims=True`, the following result has shape (3, 1).

```

>>> np.ma.average(x, axis=1, keepdims=True)
masked_array(
  data=[[0.5],
        [2.5],
        [4.5]],
  mask=False,
  fill_value=1e+20)

```

ma.conjugate (*x*, /, *out=None*, *, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True* [, *signature*]) = <numpy.ma.core._MaskedUnaryOperation object>

Return the complex conjugate, element-wise.

The complex conjugate of a complex number is obtained by changing the sign of its imaginary part.

Parameters

x

[array_like] Input value.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**For other keyword-only arguments, see the [ufunc docs](#).**Returns****y**[ndarray] The complex conjugate of *x*, with same dtype as *y*. This is a scalar if *x* is a scalar.**Notes***conj* is an alias for *conjugate*:

```
>>> np.conj is np.conjugate
True
```

Examples

```
>>> import numpy as np
>>> np.conjugate(1+2j)
(1-2j)
```

```
>>> x = np.eye(2) + 1j * np.eye(2)
>>> np.conjugate(x)
array([[ 1.-1.j,   0.-0.j],
       [ 0.-0.j,   1.-1.j]])
```

ma.corrcoef (*x*, *y=None*, *rowvar=True*, *allow_masked=True*)

Return Pearson product-moment correlation coefficients.

Except for the handling of missing data this function does the same as [numpy.corrcoef](#). For more details and examples, see [numpy.corrcoef](#).**Parameters****x**[array_like] A 1-D or 2-D array containing multiple variables and observations. Each row of *x* represents a variable, and each column a single observation of all those variables. Also see *rowvar* below.**y**[array_like, optional] An additional set of variables and observations. *y* has the same shape as *x*.**rowvar**[bool, optional] If *rowvar* is True (default), then each row represents a variable, with observations in the columns. Otherwise, the relationship is transposed: each column represents a variable, while the rows contain observations.**allow_masked**[bool, optional] If True, masked values are propagated pair-wise: if a value is masked in *x*, the corresponding value is masked in *y*. If False, raises an exception. Because *bias* is deprecated, this argument needs to be treated as keyword only to avoid a warning.**See also:**[numpy.corrcoef](#)

Equivalent function in top-level NumPy module.

cov

Estimate the covariance matrix.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[0, 1], [1, 1]], mask=[0, 1, 0, 1])
>>> np.ma.corrcoef(x)
masked_array(
  data=[--, --],
  [--, --]],
  mask=[[ True,  True],
        [ True,  True]],
  fill_value=1e+20,
  dtype=float64)
```

`ma.cov(x, y=None, rowvar=True, bias=False, allow_masked=True, ddof=None)`

Estimate the covariance matrix.

Except for the handling of missing data this function does the same as `numpy.cov`. For more details and examples, see `numpy.cov`.

By default, masked values are recognized as such. If *x* and *y* have the same shape, a common mask is allocated: if *x*[*i*, *j*] is masked, then *y*[*i*, *j*] will also be masked. Setting *allow_masked* to False will raise an exception if values are missing in either of the input arrays.

Parameters**x**

[array_like] A 1-D or 2-D array containing multiple variables and observations. Each row of *x* represents a variable, and each column a single observation of all those variables. Also see *rowvar* below.

y

[array_like, optional] An additional set of variables and observations. *y* has the same shape as *x*.

rowvar

[bool, optional] If *rowvar* is True (default), then each row represents a variable, with observations in the columns. Otherwise, the relationship is transposed: each column represents a variable, while the rows contain observations.

bias

[bool, optional] Default normalization (False) is by $(N-1)$, where *N* is the number of observations given (unbiased estimate). If *bias* is True, then normalization is by *N*. This keyword can be overridden by the keyword *ddof* in numpy versions ≥ 1.5 .

allow_masked

[bool, optional] If True, masked values are propagated pair-wise: if a value is masked in *x*, the corresponding value is masked in *y*. If False, raises a *ValueError* exception when some values are missing.

ddof

[{None, int}, optional] If not None normalization is by $(N - \text{ddof})$, where *N* is the number of observations; this overrides the value implied by *bias*. The default value is None.

Raises

ValueError

Raised if some values are missing and *allow_masked* is False.

See also:

[*numpy.cov*](#)

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[0, 1], [1, 1]], mask=[0, 1, 0, 1])
>>> y = np.ma.array([[1, 0], [0, 1]], mask=[0, 0, 1, 1])
>>> np.ma.cov(x, y)
masked_array(
  data=[ [--, --, --, --],
         [--, --, --, --],
         [--, --, --, --],
         [--, --, --, --]],
  mask=[[ True,  True,  True,  True],
        [ True,  True,  True,  True],
        [ True,  True,  True,  True],
        [ True,  True,  True,  True]],
  fill_value=1e+20,
  dtype=float64)
```

`ma.cumsum` (*self*, *axis=None*, *dtype=None*, *out=None*)

Return the cumulative sum of the array elements over the given axis.

Masked values are set to 0 internally during the computation. However, their position is saved, and the result will be masked at the same locations.

Refer to [*numpy.cumsum*](#) for full documentation.

See also:

[*numpy.ndarray.cumsum*](#)

corresponding function for ndarrays

[*numpy.cumsum*](#)

equivalent function

Notes

The mask is lost if *out* is not a valid [*ma.MaskedArray*](#) !

Arithmetic is modular when using integer types, and no error is raised on overflow.

Examples

```
>>> import numpy as np
>>> marr = np.ma.array(np.arange(10), mask=[0,0,0,1,1,1,0,0,0,0])
>>> marr.cumsum()
masked_array(data=[0, 1, 3, --, --, --, 9, 16, 24, 33],
              mask=[False, False, False,  True,  True,  True, False, False,
                    False, False],
              fill_value=999999)
```

`ma.cumprod` (*self*, *axis=None*, *dtype=None*, *out=None*)

Return the cumulative product of the array elements over the given axis.

Masked values are set to 1 internally during the computation. However, their position is saved, and the result will be masked at the same locations.

Refer to `numpy.cumprod` for full documentation.

See also:

`numpy.ndarray.cumprod`

corresponding function for ndarrays

`numpy.cumprod`

equivalent function

Notes

The mask is lost if *out* is not a valid MaskedArray !

Arithmetic is modular when using integer types, and no error is raised on overflow.

`ma.mean` (*self*, *axis=None*, *dtype=None*, *out=None*, *keepdims=<no value>*)

Returns the average of the array elements along given axis.

Masked entries are ignored, and result elements which are not finite will be masked.

Refer to `numpy.mean` for full documentation.

See also:

`numpy.ndarray.mean`

corresponding function for ndarrays

`numpy.mean`

Equivalent function

`numpy.ma.average`

Weighted average.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([1,2,3], mask=[False, False, True])
>>> a
masked_array(data=[1, 2, --],
             mask=[False, False,  True],
             fill_value=999999)
>>> a.mean()
1.5
```

`ma.median` (*a*, *axis=None*, *out=None*, *overwrite_input=False*, *keepdims=False*)

Compute the median along the specified axis.

Returns the median of the array elements.

Parameters

a

[array_like] Input array or object that can be converted to an array.

axis

[int, optional] Axis along which the medians are computed. The default (None) is to compute the median along a flattened version of the array.

out

[ndarray, optional] Alternative output array in which to place the result. It must have the same shape and buffer length as the expected output but the type will be cast if necessary.

overwrite_input

[bool, optional] If True, then allow use of memory of input array (*a*) for calculations. The input array will be modified by the call to `median`. This will save memory when you do not need to preserve the contents of the input array. Treat the input as undefined, but it will probably be fully or partially sorted. Default is False. Note that, if *overwrite_input* is True, and the input is not already an *ndarray*, an error will be raised.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.

Returns

median

[ndarray] A new array holding the result is returned unless *out* is specified, in which case a reference to *out* is returned. Return data-type is *float64* for integers and floats smaller than *float64*, or the input data-type, otherwise.

See also:

mean

Notes

Given a vector V with N non masked values, the median of V is the middle value of a sorted copy of V (V_s) - i.e. $V_s[(N-1)/2]$, when N is odd, or $\{V_s[N/2 - 1] + V_s[N/2]\}/2$ when N is even.

Examples

```
>>> import numpy as np
>>> x = np.ma.array(np.arange(8), mask=[0]*4 + [1]*4)
>>> np.ma.median(x)
1.5
```

```
>>> x = np.ma.array(np.arange(10).reshape(2, 5), mask=[0]*6 + [1]*4)
>>> np.ma.median(x)
2.5
>>> np.ma.median(x, axis=-1, overwrite_input=True)
masked_array(data=[2.0, 5.0],
              mask=[False, False],
              fill_value=1e+20)
```

`ma.power(a, b, third=None)`

Returns element-wise base array raised to power from second array.

This is the masked array version of [`numpy.power`](#). For details see [`numpy.power`](#).

See also:

[`numpy.power`](#)

Notes

The *out* argument to [`numpy.power`](#) is not supported, *third* has to be None.

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = [11.2, -3.973, 0.801, -1.41]
>>> mask = [0, 0, 0, 1]
>>> masked_x = ma.masked_array(x, mask)
>>> masked_x
masked_array(data=[11.2, -3.973, 0.801, --],
             mask=[False, False, False,  True],
             fill_value=1e+20)
>>> ma.power(masked_x, 2)
masked_array(data=[125.43999999999998, 15.784728999999999,
                  0.6416010000000001, --],
             mask=[False, False, False,  True],
             fill_value=1e+20)
>>> y = [-0.5, 2, 0, 17]
>>> masked_y = ma.masked_array(y, mask)
>>> masked_y
masked_array(data=[-0.5, 2.0, 0.0, --],
```

(continues on next page)

(continued from previous page)

```
        mask=[False, False, False,  True],
        fill_value=1e+20)
>>> ma.power(masked_x, masked_y)
masked_array(data=[0.2988071523335984, 15.784728999999999, 1.0,  --],
             mask=[False, False, False,  True],
             fill_value=1e+20)
```

ma.prod (*self*, *axis=None*, *dtype=None*, *out=None*, *keepdims=<no value>*)

Return the product of the array elements over the given axis.

Masked elements are set to 1 internally for computation.

Refer to [*numpy.prod*](#) for full documentation.

See also:

[*numpy.ndarray.prod*](#)

corresponding function for ndarrays

[*numpy.prod*](#)

equivalent function

Notes

Arithmetic is modular when using integer types, and no error is raised on overflow.

ma.std (*self*, *axis=None*, *dtype=None*, *out=None*, *ddof=0*, *keepdims=<no value>*, *mean=<no value>*)

Returns the standard deviation of the array elements along given axis.

Masked entries are ignored.

Refer to [*numpy.std*](#) for full documentation.

See also:

[*numpy.ndarray.std*](#)

corresponding function for ndarrays

[*numpy.std*](#)

Equivalent function

ma.sum (*self*, *axis=None*, *dtype=None*, *out=None*, *keepdims=<no value>*)

Return the sum of the array elements over the given axis.

Masked elements are set to 0 internally.

Refer to [*numpy.sum*](#) for full documentation.

See also:

[*numpy.ndarray.sum*](#)

corresponding function for ndarrays

[*numpy.sum*](#)

equivalent function

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[1,2,3],[4,5,6],[7,8,9]], mask=[0] + [1,0]*4)
>>> x
masked_array(
  data=[[1, --, 3],
        [--, 5, --],
        [7, --, 9]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=999999)
>>> x.sum()
25
>>> x.sum(axis=1)
masked_array(data=[4, 5, 16],
             mask=[False, False, False],
             fill_value=999999)
>>> x.sum(axis=0)
masked_array(data=[8, 5, 12],
             mask=[False, False, False],
             fill_value=999999)
>>> print(type(x.sum(axis=0, dtype=np.int64)[0]))
<class 'numpy.int64'>
```

`ma.var` (*self*, *axis=None*, *dtype=None*, *out=None*, *ddof=0*, *keepdims=<no value>*, *mean=<no value>*)

Compute the variance along the specified axis.

Returns the variance of the array elements, a measure of the spread of a distribution. The variance is computed for the flattened array by default, otherwise over the specified axis.

Parameters

a

[array_like] Array containing numbers whose variance is desired. If *a* is not an array, a conversion is attempted.

axis

[None or int or tuple of ints, optional] Axis or axes along which the variance is computed. The default is to compute the variance of the flattened array. If this is a tuple of ints, a variance is performed over multiple axes, instead of a single axis or all the axes as before.

dtype

[data-type, optional] Type to use in computing the variance. For arrays of integer type the default is `float64`; for arrays of float types it is the same as the array type.

out

[ndarray, optional] Alternate output array in which to place the result. It must have the same shape as the expected output, but the type is cast if necessary.

ddof

[{int, float}, optional] “Delta Degrees of Freedom”: the divisor used in the calculation is $N - \text{ddof}$, where N represents the number of elements. By default *ddof* is zero. See notes for details about use of *ddof*.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input

array.

If the default value is passed, then *keepdims* will not be passed through to the *var* method of sub-classes of *ndarray*, however any non-default value will be. If the sub-class' method does not implement *keepdims* any exceptions will be raised.

where

[array_like of bool, optional] Elements to include in the variance. See *reduce* for details.

New in version 1.20.0.

mean

[array like, optional] Provide the mean to prevent its recalculation. The mean should have a shape as if it was calculated with *keepdims=True*. The axis for the calculation of the mean should be the same as used in the call to this var function.

New in version 2.0.0.

correction

[{int, float}, optional] Array API compatible name for the *ddof* parameter. Only one of them can be provided at the same time.

New in version 2.0.0.

Returns**variance**

[ndarray, see dtype parameter above] If *out=None*, returns a new array containing the variance; otherwise, a reference to the output array is returned.

See also:

std, *mean*, *nanmean*, *nanstd*, *nanvar*
ufuncs-output-type

Notes

There are several common variants of the array variance calculation. Assuming the input *a* is a one-dimensional NumPy array and *mean* is either provided as an argument or computed as *a.mean()*, NumPy computes the variance of an array as:

```
N = len(a)
d2 = abs(a - mean)**2 # abs is for complex `a`
var = d2.sum() / (N - ddof) # note use of `ddof`
```

Different values of the argument *ddof* are useful in different contexts. NumPy's default *ddof=0* corresponds with the expression:

$$\frac{\sum_i |a_i - \bar{a}|^2}{N}$$

which is sometimes called the “population variance” in the field of statistics because it applies the definition of variance to *a* as if *a* were a complete population of possible observations.

Many other libraries define the variance of an array differently, e.g.:

$$\frac{\sum_i |a_i - \bar{a}|^2}{N - 1}$$

In statistics, the resulting quantity is sometimes called the “sample variance” because if *a* is a random sample from a larger population, this calculation provides an unbiased estimate of the variance of the population. The use of

$N - 1$ in the denominator is often called “Bessel’s correction” because it corrects for bias (toward lower values) in the variance estimate introduced when the sample mean of a is used in place of the true mean of the population. For this quantity, use `ddof=1`.

Note that for complex numbers, the absolute value is taken before squaring, so that the result is always real and nonnegative.

For floating-point input, the variance is computed using the same precision the input has. Depending on the input data, this can cause the results to be inaccurate, especially for `float32` (see example below). Specifying a higher-accuracy accumulator using the `dtype` keyword can alleviate this issue.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> np.var(a)
1.25
>>> np.var(a, axis=0)
array([1., 1.])
>>> np.var(a, axis=1)
array([0.25, 0.25])
```

In single precision, `var()` can be inaccurate:

```
>>> a = np.zeros((2, 512*512), dtype=np.float32)
>>> a[0, :] = 1.0
>>> a[1, :] = 0.1
>>> np.var(a)
np.float32(0.20250003)
```

Computing the variance in `float64` is more accurate:

```
>>> np.var(a, dtype=np.float64)
0.20249999932944759 # may vary
>>> ((1-0.55)**2 + (0.1-0.55)**2)/2
0.2025
```

Specifying a `where` argument:

```
>>> a = np.array([[14, 8, 11, 10], [7, 9, 10, 11], [10, 15, 5, 10]])
>>> np.var(a)
6.833333333333333 # may vary
>>> np.var(a, where=[[True], [True], [False]])
4.0
```

Using the `mean` keyword to save computation time:

```
>>> import numpy as np
>>> from timeit import timeit
>>>
>>> a = np.array([[14, 8, 11, 10], [7, 9, 10, 11], [10, 15, 5, 10]])
>>> mean = np.mean(a, axis=1, keepdims=True)
>>>
>>> g = globals()
>>> n = 10000
>>> t1 = timeit("var = np.var(a, axis=1, mean=mean)", globals=g, number=n)
>>> t2 = timeit("var = np.var(a, axis=1)", globals=g, number=n)
```

(continues on next page)

(continued from previous page)

```
>>> print(f'Percentage execution time saved {100*(t2-t1)/t2:.0f}%')
Percentage execution time saved 32%
```

method

`ma.MaskedArray.anom` (*axis=None, dtype=None*)

Compute the anomalies (deviations from the arithmetic mean) along the given axis.

Returns an array of anomalies, with the same shape as the input and where the arithmetic mean is computed along the given axis.

Parameters

axis

[int, optional] Axis over which the anomalies are taken. The default is to use the mean of the flattened array as reference.

dtype

[dtype, optional] Type to use in computing the variance. For arrays of integer type the default is float32; for arrays of float types it is the same as the array type.

See also:

[`mean`](#)

Compute the mean of the array.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([1,2,3])
>>> a.anom()
masked_array(data=[-1.,  0.,  1.],
             mask=False,
             fill_value=1e+20)
```

method

`ma.MaskedArray.cumprod` (*axis=None, dtype=None, out=None*)

Return the cumulative product of the array elements over the given axis.

Masked values are set to 1 internally during the computation. However, their position is saved, and the result will be masked at the same locations.

Refer to [`numpy.cumprod`](#) for full documentation.

See also:

[`numpy.ndarray.cumprod`](#)

corresponding function for ndarrays

[`numpy.cumprod`](#)

equivalent function

Notes

The mask is lost if *out* is not a valid `MaskedArray` !

Arithmetic is modular when using integer types, and no error is raised on overflow.

method

`ma.MaskedArray.cumsum` (*axis=None, dtype=None, out=None*)

Return the cumulative sum of the array elements over the given axis.

Masked values are set to 0 internally during the computation. However, their position is saved, and the result will be masked at the same locations.

Refer to `numpy.cumsum` for full documentation.

See also:

`numpy.ndarray.cumsum`

corresponding function for ndarrays

`numpy.cumsum`

equivalent function

Notes

The mask is lost if *out* is not a valid `ma.MaskedArray` !

Arithmetic is modular when using integer types, and no error is raised on overflow.

Examples

```
>>> import numpy as np
>>> marr = np.ma.array(np.arange(10), mask=[0,0,0,1,1,1,0,0,0,0])
>>> marr.cumsum()
masked_array(data=[0, 1, 3, --, --, --, 9, 16, 24, 33],
              mask=[False, False, False,  True,  True,  True, False, False,
                    False, False],
              fill_value=999999)
```

method

`ma.MaskedArray.mean` (*axis=None, dtype=None, out=None, keepdims=<no value>*)

Returns the average of the array elements along given axis.

Masked entries are ignored, and result elements which are not finite will be masked.

Refer to `numpy.mean` for full documentation.

See also:

`numpy.ndarray.mean`

corresponding function for ndarrays

`numpy.mean`

Equivalent function

`numpy.ma.average`

Weighted average.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([1,2,3], mask=[False, False, True])
>>> a
masked_array(data=[1, 2, --],
             mask=[False, False,  True],
             fill_value=999999)
>>> a.mean()
1.5
```

method

`ma.MaskedArray.prod` (*axis=None, dtype=None, out=None, keepdims=<no value>*)

Return the product of the array elements over the given axis.

Masked elements are set to 1 internally for computation.

Refer to [`numpy.prod`](#) for full documentation.

See also:

[`numpy.ndarray.prod`](#)

corresponding function for ndarrays

[`numpy.prod`](#)

equivalent function

Notes

Arithmetic is modular when using integer types, and no error is raised on overflow.

method

`ma.MaskedArray.std` (*axis=None, dtype=None, out=None, ddof=0, keepdims=<no value>, mean=<no value>*)

Returns the standard deviation of the array elements along given axis.

Masked entries are ignored.

Refer to [`numpy.std`](#) for full documentation.

See also:

[`numpy.ndarray.std`](#)

corresponding function for ndarrays

[`numpy.std`](#)

Equivalent function

method

`ma.MaskedArray.sum` (*axis=None, dtype=None, out=None, keepdims=<no value>*)

Return the sum of the array elements over the given axis.

Masked elements are set to 0 internally.

Refer to [`numpy.sum`](#) for full documentation.

See also:

`numpy.ndarray.sum`

corresponding function for ndarrays

`numpy.sum`

equivalent function

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[1,2,3],[4,5,6],[7,8,9]], mask=[0] + [1,0]*4)
>>> x
masked_array(
  data=[[1, --, 3],
        [--, 5, --],
        [7, --, 9]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=999999)
>>> x.sum()
25
>>> x.sum(axis=1)
masked_array(data=[4, 5, 16],
             mask=[False, False, False],
             fill_value=999999)
>>> x.sum(axis=0)
masked_array(data=[8, 5, 12],
             mask=[False, False, False],
             fill_value=999999)
>>> print(type(x.sum(axis=0, dtype=np.int64)[0]))
<class 'numpy.int64'>
```

method

`ma.MaskedArray.var` (*axis=None, dtype=None, out=None, ddof=0, keepdims=<no value>, mean=<no value>*)

Compute the variance along the specified axis.

Returns the variance of the array elements, a measure of the spread of a distribution. The variance is computed for the flattened array by default, otherwise over the specified axis.

Parameters

a

[array_like] Array containing numbers whose variance is desired. If *a* is not an array, a conversion is attempted.

axis

[None or int or tuple of ints, optional] Axis or axes along which the variance is computed. The default is to compute the variance of the flattened array. If this is a tuple of ints, a variance is performed over multiple axes, instead of a single axis or all the axes as before.

dtype

[data-type, optional] Type to use in computing the variance. For arrays of integer type the default is `float64`; for arrays of float types it is the same as the array type.

out

[ndarray, optional] Alternate output array in which to place the result. It must have the same shape as the expected output, but the type is cast if necessary.

ddof

[{int, float}, optional] “Delta Degrees of Freedom”: the divisor used in the calculation is $N - \text{ddof}$, where N represents the number of elements. By default *ddof* is zero. See notes for details about use of *ddof*.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.

If the default value is passed, then *keepdims* will not be passed through to the *var* method of sub-classes of *ndarray*, however any non-default value will be. If the sub-class’ method does not implement *keepdims* any exceptions will be raised.

where

[array_like of bool, optional] Elements to include in the variance. See *reduce* for details.

New in version 1.20.0.

mean

[array like, optional] Provide the mean to prevent its recalculation. The mean should have a shape as if it was calculated with *keepdims*=True. The axis for the calculation of the mean should be the same as used in the call to this var function.

New in version 2.0.0.

correction

[{int, float}, optional] Array API compatible name for the *ddof* parameter. Only one of them can be provided at the same time.

New in version 2.0.0.

Returns**variance**

[ndarray, see dtype parameter above] If *out*=None, returns a new array containing the variance; otherwise, a reference to the output array is returned.

See also:

std, *mean*, *nanmean*, *nanstd*, *nanvar*
ufuncs-output-type

Notes

There are several common variants of the array variance calculation. Assuming the input *a* is a one-dimensional NumPy array and *mean* is either provided as an argument or computed as *a.mean()*, NumPy computes the variance of an array as:

```
N = len(a)
d2 = abs(a - mean)**2 # abs is for complex `a`
var = d2.sum() / (N - ddof) # note use of `ddof`
```

Different values of the argument *ddof* are useful in different contexts. NumPy’s default *ddof*=0 corresponds with the expression:

$$\frac{\sum_i |a_i - \bar{a}|^2}{N}$$

which is sometimes called the “population variance” in the field of statistics because it applies the definition of variance to a as if a were a complete population of possible observations.

Many other libraries define the variance of an array differently, e.g.:

$$\frac{\sum_i |a_i - \bar{a}|^2}{N - 1}$$

In statistics, the resulting quantity is sometimes called the “sample variance” because if a is a random sample from a larger population, this calculation provides an unbiased estimate of the variance of the population. The use of $N - 1$ in the denominator is often called “Bessel’s correction” because it corrects for bias (toward lower values) in the variance estimate introduced when the sample mean of a is used in place of the true mean of the population. For this quantity, use `ddof=1`.

Note that for complex numbers, the absolute value is taken before squaring, so that the result is always real and nonnegative.

For floating-point input, the variance is computed using the same precision the input has. Depending on the input data, this can cause the results to be inaccurate, especially for `float32` (see example below). Specifying a higher-accuracy accumulator using the `dtype` keyword can alleviate this issue.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> np.var(a)
1.25
>>> np.var(a, axis=0)
array([1., 1.])
>>> np.var(a, axis=1)
array([0.25, 0.25])
```

In single precision, `var()` can be inaccurate:

```
>>> a = np.zeros((2, 512*512), dtype=np.float32)
>>> a[0, :] = 1.0
>>> a[1, :] = 0.1
>>> np.var(a)
np.float32(0.20250003)
```

Computing the variance in `float64` is more accurate:

```
>>> np.var(a, dtype=np.float64)
0.20249999932944759 # may vary
>>> ((1-0.55)**2 + (0.1-0.55)**2)/2
0.2025
```

Specifying a `where` argument:

```
>>> a = np.array([[14, 8, 11, 10], [7, 9, 10, 11], [10, 15, 5, 10]])
>>> np.var(a)
6.833333333333333 # may vary
>>> np.var(a, where=[[True], [True], [False]])
4.0
```

Using the `mean` keyword to save computation time:

```

>>> import numpy as np
>>> from timeit import timeit
>>>
>>> a = np.array([[14, 8, 11, 10], [7, 9, 10, 11], [10, 15, 5, 10]])
>>> mean = np.mean(a, axis=1, keepdims=True)
>>>
>>> g = globals()
>>> n = 10000
>>> t1 = timeit("var = np.var(a, axis=1, mean=mean)", globals=g, number=n)
>>> t2 = timeit("var = np.var(a, axis=1)", globals=g, number=n)
>>> print(f'Percentage execution time saved {100*(t2-t1)/t2:.0f}%')

```

Percentage execution time saved 32%

Minimum/maximum

<code>ma.argmax(self[, axis, fill_value, out, ...])</code>	Returns array of indices of the maximum values along the given axis.
<code>ma.argmin(self[, axis, fill_value, out, ...])</code>	Return array of indices to the minimum values along the given axis.
<code>ma.max(obj[, axis, out, fill_value, keepdims])</code>	Return the maximum along a given axis.
<code>ma.min(obj[, axis, out, fill_value, keepdims])</code>	Return the minimum along a given axis.
<code>ma.ptp(obj[, axis, out, fill_value, keepdims])</code>	Return (maximum - minimum) along the given dimension (i.e. peak-to-peak value).
<code>ma.diff(a, /[, n, axis, prepend, append])</code>	Calculate the n-th discrete difference along the given axis.
<code>ma.MaskedArray.argmax([axis, fill_value, ...])</code>	Returns array of indices of the maximum values along the given axis.
<code>ma.MaskedArray.argmin([axis, fill_value, ...])</code>	Return array of indices to the minimum values along the given axis.
<code>ma.MaskedArray.max([axis, out, fill_value, ...])</code>	Return the maximum along a given axis.
<code>ma.MaskedArray.min([axis, out, fill_value, ...])</code>	Return the minimum along a given axis.
<code>ma.MaskedArray.ptp([axis, out, fill_value, ...])</code>	Return (maximum - minimum) along the given dimension (i.e. peak-to-peak value).

`ma.argmax` (*self*, *axis=None*, *fill_value=None*, *out=None*, *, *keepdims=<no value>*)

Returns array of indices of the maximum values along the given axis. Masked values are treated as if they had the value *fill_value*.

Parameters

axis

[{None, integer}] If None, the index is into the flattened array, otherwise along the specified axis

fill_value

[scalar or None, optional] Value used to fill in the masked values. If None, the output of `maximum_fill_value(self._data)` is used instead.

out

[{None, array}, optional] Array into which the result can be placed. Its type is preserved and it must be of the right shape to hold the output.

Returns

index_array
 [{integer_array}]

Examples

```
>>> import numpy as np
>>> a = np.arange(6).reshape(2, 3)
>>> a.argmax()
5
>>> a.argmax(0)
array([1, 1, 1])
>>> a.argmax(1)
array([2, 2])
```

ma.argmin (*self*, *axis=None*, *fill_value=None*, *out=None*, *, *keepdims=<no value>*)

Return array of indices to the minimum values along the given axis.

Parameters

axis

[{None, integer}] If None, the index is into the flattened array, otherwise along the specified axis

fill_value

[scalar or None, optional] Value used to fill in the masked values. If None, the output of `minimum_fill_value(self._data)` is used instead.

out

[{None, array}, optional] Array into which the result can be placed. Its type is preserved and it must be of the right shape to hold the output.

Returns

ndarray or scalar

If multi-dimension input, returns a new ndarray of indices to the minimum values along the given axis. Otherwise, returns a scalar of index to the minimum values along the given axis.

Examples

```
>>> import numpy as np
>>> x = np.ma.array(np.arange(4), mask=[1, 1, 0, 0])
>>> x = x.reshape((2, 2))
>>> x
masked_array(
  data=[[--, --],
        [2, 3]],
  mask=[[ True,  True],
        [False, False]],
  fill_value=999999)
>>> x.argmin(axis=0, fill_value=-1)
array([0, 0])
>>> x.argmin(axis=0, fill_value=9)
array([1, 1])
```

ma.max (*obj*, *axis=None*, *out=None*, *fill_value=None*, *keepdims=<no value>*)

Return the maximum along a given axis.

Parameters**axis**

[None or int or tuple of ints, optional] Axis along which to operate. By default, `axis` is `None` and the flattened input is used. If this is a tuple of ints, the maximum is selected over multiple axes, instead of a single axis or all the axes as before.

out

[array_like, optional] Alternative output array in which to place the result. Must be of the same shape and buffer length as the expected output.

fill_value

[scalar or None, optional] Value used to fill in the masked values. If `None`, use the output of `maximum_fill_value()`.

keepdims

[bool, optional] If this is set to `True`, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the array.

Returns**amax**

[array_like] New array holding the result. If `out` was specified, `out` is returned.

See also:**`ma.maximum_fill_value`**

Returns the maximum filling value for a given datatype.

Examples

```
>>> import numpy.ma as ma
>>> x = [[-1., 2.5], [4., -2.], [3., 0.]]
>>> mask = [[0, 0], [1, 0], [1, 0]]
>>> masked_x = ma.masked_array(x, mask)
>>> masked_x
masked_array(
  data=[[-1.0, 2.5],
        [--, -2.0],
        [--, 0.0]],
  mask=[[False, False],
        [ True, False],
        [ True, False]],
  fill_value=1e+20)
>>> ma.max(masked_x)
2.5
>>> ma.max(masked_x, axis=0)
masked_array(data=[-1.0, 2.5],
             mask=[False, False],
             fill_value=1e+20)
>>> ma.max(masked_x, axis=1, keepdims=True)
masked_array(
  data=[[2.5],
        [-2.0],
        [0.0]],
  mask=[[False],
        [False],
        [False]],
  fill_value=1e+20)
```

(continues on next page)

(continued from previous page)

```

    fill_value=1e+20)
>>> mask = [[1, 1], [1, 1], [1, 1]]
>>> masked_x = ma.masked_array(x, mask)
>>> ma.max(masked_x, axis=1)
masked_array(data=[--, --, --],
             mask=[ True,  True,  True],
             fill_value=1e+20,
             dtype=float64)

```

ma.min (*obj*, *axis=None*, *out=None*, *fill_value=None*, *keepdims=<no value>*)

Return the minimum along a given axis.

Parameters

axis

[None or int or tuple of ints, optional] Axis along which to operate. By default, *axis* is None and the flattened input is used. If this is a tuple of ints, the minimum is selected over multiple axes, instead of a single axis or all the axes as before.

out

[array_like, optional] Alternative output array in which to place the result. Must be of the same shape and buffer length as the expected output.

fill_value

[scalar or None, optional] Value used to fill in the masked values. If None, use the output of *minimum_fill_value*.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the array.

Returns

amin

[array_like] New array holding the result. If *out* was specified, *out* is returned.

See also:

ma.minimum_fill_value

Returns the minimum filling value for a given datatype.

Examples

```

>>> import numpy.ma as ma
>>> x = [[1., -2., 3.], [0.2, -0.7, 0.1]]
>>> mask = [[1, 1, 0], [0, 0, 1]]
>>> masked_x = ma.masked_array(x, mask)
>>> masked_x
masked_array(
  data=[[--, --, 3.0],
        [0.2, -0.7, --]],
  mask=[[ True,  True, False],
        [False, False,  True]],
  fill_value=1e+20)
>>> ma.min(masked_x)
-0.7

```

(continues on next page)

(continued from previous page)

```

>>> ma.min(masked_x, axis=-1)
masked_array(data=[3.0, -0.7],
             mask=[False, False],
             fill_value=1e+20)
>>> ma.min(masked_x, axis=0, keepdims=True)
masked_array(data=[[0.2, -0.7, 3.0]],
             mask=[[False, False, False]],
             fill_value=1e+20)
>>> mask = [[1, 1, 1,], [1, 1, 1]]
>>> masked_x = ma.masked_array(x, mask)
>>> ma.min(masked_x, axis=0)
masked_array(data=[--, --, --],
             mask=[ True,  True,  True],
             fill_value=1e+20,
             dtype=float64)

```

`ma.ptp` (*obj*, *axis=None*, *out=None*, *fill_value=None*, *keepdims=<no value>*)

Return (maximum - minimum) along the given dimension (i.e. peak-to-peak value).

Warning: `ptp` preserves the data type of the array. This means the return value for an input of signed integers with *n* bits (e.g. `np.int8`, `np.int16`, etc) is also a signed integer with *n* bits. In that case, peak-to-peak values greater than $2^{n-1} - 1$ will be returned as negative values. An example with a work-around is shown below.

Parameters

axis

[{None, int}, optional] Axis along which to find the peaks. If None (default) the flattened array is used.

out

[{None, array_like}, optional] Alternative output array in which to place the result. It must have the same shape and buffer length as the expected output but the type will be cast if necessary.

fill_value

[scalar or None, optional] Value used to fill in the masked values.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the array.

Returns

ptp

[ndarray.] A new array holding the result, unless `out` was specified, in which case a reference to `out` is returned.

Examples

```
>>> import numpy as np
>>> x = np.ma.MaskedArray([[4, 9, 2, 10],
...                        [6, 9, 7, 12]])
```

```
>>> x.ptp(axis=1)
masked_array(data=[8, 6],
             mask=False,
             fill_value=999999)
```

```
>>> x.ptp(axis=0)
masked_array(data=[2, 0, 5, 2],
             mask=False,
             fill_value=999999)
```

```
>>> x.ptp()
10
```

This example shows that a negative value can be returned when the input is an array of signed integers.

```
>>> y = np.ma.MaskedArray([[1, 127],
...                        [0, 127],
...                        [-1, 127],
...                        [-2, 127]]), dtype=np.int8)
>>> y.ptp(axis=1)
masked_array(data=[ 126, 127, -128, -127],
             mask=False,
             fill_value=np.int64(999999),
             dtype=int8)
```

A work-around is to use the `view()` method to view the result as unsigned integers with the same bit width:

```
>>> y.ptp(axis=1).view(np.uint8)
masked_array(data=[126, 127, 128, 129],
             mask=False,
             fill_value=np.uint64(999999),
             dtype=uint8)
```

ma.diff (*a*, /, *n*=1, *axis*=-1, *prepend*=<no value>, *append*=<no value>)

Calculate the *n*-th discrete difference along the given axis. The first difference is given by `out[i] = a[i+1] - a[i]` along the given axis, higher differences are calculated by using `diff` recursively. Preserves the input mask.

Parameters

a

[array_like] Input array

n

[int, optional] The number of times values are differenced. If zero, the input is returned as-is.

axis

[int, optional] The axis along which the difference is taken, default is the last axis.

prepend, append

[array_like, optional] Values to prepend or append to *a* along axis prior to performing the difference. Scalar values are expanded to arrays with length 1 in the direction of axis and the

shape of the input array in along all other axes. Otherwise the dimension and shape must match *a* except along axis.

Returns

diff

[MaskedArray] The *n*-th differences. The shape of the output is the same as *a* except along *axis* where the dimension is smaller by *n*. The type of the output is the same as the type of the difference between any two elements of *a*. This is the same as the type of *a* in most cases. A notable exception is `datetime64`, which results in a `timedelta64` output array.

See also:

`numpy.diff`

Equivalent function in the top-level NumPy module.

Notes

Type is preserved for boolean arrays, so the result will contain *False* when consecutive elements are the same and *True* when they differ.

For unsigned integer arrays, the results will also be unsigned. This should not be surprising, as the result is consistent with calculating the difference directly:

```
>>> u8_arr = np.array([1, 0], dtype=np.uint8)
>>> np.ma.diff(u8_arr)
masked_array(data=[255],
             mask=False,
             fill_value=np.uint64(999999),
             dtype=uint8)
>>> u8_arr[1,...] - u8_arr[0,...]
np.uint8(255)
```

If this is not desirable, then the array should be cast to a larger integer type first:

```
>>> i16_arr = u8_arr.astype(np.int16)
>>> np.ma.diff(i16_arr)
masked_array(data=[-1],
             mask=False,
             fill_value=np.int64(999999),
             dtype=int16)
```

Examples

```
>>> import numpy as np
>>> a = np.array([1, 2, 3, 4, 7, 0, 2, 3])
>>> x = np.ma.masked_where(a < 2, a)
>>> np.ma.diff(x)
masked_array(data=[--, 1, 1, 3, --, --, 1],
             mask=[ True, False, False, False,  True,  True, False],
             fill_value=999999)
```

```
>>> np.ma.diff(x, n=2)
masked_array(data=[--, 0, 2, --, --, --],
             mask=[ True, False, False,  True,  True,  True],
             fill_value=999999)
```

```
>>> a = np.array([[1, 3, 1, 5, 10], [0, 1, 5, 6, 8]])
>>> x = np.ma.masked_equal(a, value=1)
>>> np.ma.diff(x)
masked_array(
  data=[--, --, --, 5],
    [--, --, 1, 2]],
  mask=[ [ True,  True,  True, False],
        [ True,  True, False, False]],
  fill_value=1)
```

```
>>> np.ma.diff(x, axis=0)
masked_array(data=[--, --, --, 1, -2]],
  mask=[ [ True,  True,  True, False, False]],
  fill_value=1)
```

method

`ma.MaskedArray.argmax` (*axis=None*, *fill_value=None*, *out=None*, *, *keepdims=<no value>*)

Returns array of indices of the maximum values along the given axis. Masked values are treated as if they had the value `fill_value`.

Parameters

axis

[{None, integer}] If None, the index is into the flattened array, otherwise along the specified axis

fill_value

[scalar or None, optional] Value used to fill in the masked values. If None, the output of `maximum_fill_value(self._data)` is used instead.

out

[{None, array}, optional] Array into which the result can be placed. Its type is preserved and it must be of the right shape to hold the output.

Returns

index_array

[{integer_array}]

Examples

```
>>> import numpy as np
>>> a = np.arange(6).reshape(2, 3)
>>> a.argmax()
5
>>> a.argmax(0)
array([1, 1, 1])
>>> a.argmax(1)
array([2, 2])
```

method

`ma.MaskedArray.argmin` (*axis=None*, *fill_value=None*, *out=None*, *, *keepdims=<no value>*)

Return array of indices to the minimum values along the given axis.

Parameters

axis

[{None, integer}] If None, the index is into the flattened array, otherwise along the specified axis

fill_value

[scalar or None, optional] Value used to fill in the masked values. If None, the output of `minimum_fill_value(self._data)` is used instead.

out

[{None, array}, optional] Array into which the result can be placed. Its type is preserved and it must be of the right shape to hold the output.

Returns**ndarray or scalar**

If multi-dimension input, returns a new ndarray of indices to the minimum values along the given axis. Otherwise, returns a scalar of index to the minimum values along the given axis.

Examples

```
>>> import numpy as np
>>> x = np.ma.array(np.arange(4), mask=[1, 1, 0, 0])
>>> x = x.reshape((2, 2))
>>> x
masked_array(
  data=[--, --,
        [2, 3]],
  mask=[[ True,  True],
        [False, False]],
  fill_value=999999)
>>> x.argmax(axis=0, fill_value=-1)
array([0, 0])
>>> x.argmax(axis=0, fill_value=9)
array([1, 1])
```

method

`ma.MaskedArray.max` (*axis=None*, *out=None*, *fill_value=None*, *keepdims=<no value>*)

Return the maximum along a given axis.

Parameters**axis**

[None or int or tuple of ints, optional] Axis along which to operate. By default, `axis` is None and the flattened input is used. If this is a tuple of ints, the maximum is selected over multiple axes, instead of a single axis or all the axes as before.

out

[array_like, optional] Alternative output array in which to place the result. Must be of the same shape and buffer length as the expected output.

fill_value

[scalar or None, optional] Value used to fill in the masked values. If None, use the output of `maximum_fill_value()`.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the array.

Returns**amax**

[array_like] New array holding the result. If `out` was specified, `out` is returned.

See also:**`ma.maximum_fill_value`**

Returns the maximum filling value for a given datatype.

Examples

```
>>> import numpy.ma as ma
>>> x = [[-1., 2.5], [4., -2.], [3., 0.]]
>>> mask = [[0, 0], [1, 0], [1, 0]]
>>> masked_x = ma.masked_array(x, mask)
>>> masked_x
masked_array(
  data=[[-1.0, 2.5],
        [--, -2.0],
        [--, 0.0]],
  mask=[[False, False],
        [ True, False],
        [ True, False]],
  fill_value=1e+20)
>>> ma.max(masked_x)
2.5
>>> ma.max(masked_x, axis=0)
masked_array(data=[-1.0, 2.5],
             mask=[False, False],
             fill_value=1e+20)
>>> ma.max(masked_x, axis=1, keepdims=True)
masked_array(
  data=[[2.5],
        [-2.0],
        [0.0]],
  mask=[[False],
        [False],
        [False]],
  fill_value=1e+20)
>>> mask = [[1, 1], [1, 1], [1, 1]]
>>> masked_x = ma.masked_array(x, mask)
>>> ma.max(masked_x, axis=1)
masked_array(data=[--, --, --],
             mask=[ True,  True,  True],
             fill_value=1e+20,
             dtype=float64)
```

method

`ma.MaskedArray.min` (*axis=None, out=None, fill_value=None, keepdims=<no value>*)

Return the minimum along a given axis.

Parameters**axis**

[None or int or tuple of ints, optional] Axis along which to operate. By default, `axis` is None

and the flattened input is used. If this is a tuple of ints, the minimum is selected over multiple axes, instead of a single axis or all the axes as before.

out

[array_like, optional] Alternative output array in which to place the result. Must be of the same shape and buffer length as the expected output.

fill_value

[scalar or None, optional] Value used to fill in the masked values. If None, use the output of *minimum_fill_value*.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the array.

Returns**amin**

[array_like] New array holding the result. If out was specified, out is returned.

See also:***ma.minimum_fill_value***

Returns the minimum filling value for a given datatype.

Examples

```
>>> import numpy.ma as ma
>>> x = [[1., -2., 3.], [0.2, -0.7, 0.1]]
>>> mask = [[1, 1, 0], [0, 0, 1]]
>>> masked_x = ma.masked_array(x, mask)
>>> masked_x
masked_array(
  data=[--, --, 3.0],
        [0.2, -0.7, --]],
  mask=[ [ True,  True, False],
        [False, False,  True]],
  fill_value=1e+20)
>>> ma.min(masked_x)
-0.7
>>> ma.min(masked_x, axis=-1)
masked_array(data=[3.0, -0.7],
             mask=[False, False],
             fill_value=1e+20)
>>> ma.min(masked_x, axis=0, keepdims=True)
masked_array(data=[[0.2, -0.7, 3.0]],
             mask=[[False, False, False]],
             fill_value=1e+20)
>>> mask = [[1, 1, 1], [1, 1, 1]]
>>> masked_x = ma.masked_array(x, mask)
>>> ma.min(masked_x, axis=0)
masked_array(data=[--, --, --],
             mask=[ True,  True,  True],
             fill_value=1e+20,
             dtype=float64)
```

method

`ma.MaskedArray.ptp` (*axis=None, out=None, fill_value=None, keepdims=False*)

Return (maximum - minimum) along the given dimension (i.e. peak-to-peak value).

Warning: `ptp` preserves the data type of the array. This means the return value for an input of signed integers with n bits (e.g. `np.int8`, `np.int16`, etc) is also a signed integer with n bits. In that case, peak-to-peak values greater than $2^{n-1} - 1$ will be returned as negative values. An example with a work-around is shown below.

Parameters

axis

[{None, int}, optional] Axis along which to find the peaks. If None (default) the flattened array is used.

out

[{None, array_like}, optional] Alternative output array in which to place the result. It must have the same shape and buffer length as the expected output but the type will be cast if necessary.

fill_value

[scalar or None, optional] Value used to fill in the masked values.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the array.

Returns

ptp

[ndarray.] A new array holding the result, unless `out` was specified, in which case a reference to `out` is returned.

Examples

```
>>> import numpy as np
>>> x = np.ma.MaskedArray([[4, 9, 2, 10],
...                        [6, 9, 7, 12]])
```

```
>>> x.ptp(axis=1)
masked_array(data=[8, 6],
             mask=False,
             fill_value=999999)
```

```
>>> x.ptp(axis=0)
masked_array(data=[2, 0, 5, 2],
             mask=False,
             fill_value=999999)
```

```
>>> x.ptp()
10
```

This example shows that a negative value can be returned when the input is an array of signed integers.

```
>>> y = np.ma.MaskedArray([[1, 127],
...                        [0, 127],
```

(continues on next page)

(continued from previous page)

```

...             [-1, 127],
...             [-2, 127]], dtype=np.int8)
>>> y.ptp(axis=1)
masked_array(data=[ 126,  127, -128, -127],
             mask=False,
             fill_value=np.int64(999999),
             dtype=int8)

```

A work-around is to use the `view()` method to view the result as unsigned integers with the same bit width:

```

>>> y.ptp(axis=1).view(np.uint8)
masked_array(data=[126, 127, 128, 129],
             mask=False,
             fill_value=np.uint64(999999),
             dtype=uint8)

```

Sorting

<code>ma.argsort(a[, axis, kind, order, endwith, ...])</code>	Return an ndarray of indices that sort the array along the specified axis.
<code>ma.sort(a[, axis, kind, order, endwith, ...])</code>	Return a sorted copy of the masked array.
<code>ma.MaskedArray.argsort([axis, kind, order, ...])</code>	Return an ndarray of indices that sort the array along the specified axis.
<code>ma.MaskedArray.sort([axis, kind, order, ...])</code>	Sort the array, in-place

ma.argsort (*a*, *axis*=<no value>, *kind*=None, *order*=None, *endwith*=True, *fill_value*=None, *, *stable*=None, *descending*=None)

Return an ndarray of indices that sort the array along the specified axis. Masked values are filled beforehand to *fill_value*.

Parameters

axis

[int, optional] Axis along which to sort. If None, the default, the flattened array is used.

kind

[{'quicksort', 'mergesort', 'heapsort', 'stable'}, optional] The sorting algorithm used.

order

[str or list of str, optional] When *a* is an array with fields defined, this argument specifies which fields to compare first, second, etc. Not all fields need be specified.

endwith

[{True, False}, optional] Whether missing values (if any) should be treated as the largest values (True) or the smallest values (False) When the array contains unmasked values at the same extremes of the datatype, the ordering of these values and the masked values is undefined.

fill_value

[scalar or None, optional] Value used internally for the masked values. If *fill_value* is not None, it supersedes *endwith*.

stable

[bool, optional] Only for compatibility with `np.argsort`. Ignored.

descending

[bool, optional] Only for compatibility with `np.sort`. Ignored.

Returns**index_array**

[ndarray, int] Array of indices that sort *a* along the specified axis. In other words, `a[index_array]` yields a sorted *a*.

See also:**`ma.MaskedArray.sort`**

Describes sorting algorithms used.

`lexsort`

Indirect stable sort with multiple keys.

`numpy.ndarray.sort`

Inplace sort.

Notes

See [sort](#) for notes on the different sorting algorithms.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([3,2,1], mask=[False, False, True])
>>> a
masked_array(data=[3, 2, --],
              mask=[False, False,  True],
              fill_value=999999)
>>> a.argsort()
array([1, 0, 2])
```

`ma.sort(a, axis=-1, kind=None, order=None, endwith=True, fill_value=None, *, stable=None, descending=None)`

Return a sorted copy of the masked array.

Equivalent to creating a copy of the array and applying the `MaskedArray.sort()` method.

Refer to `MaskedArray.sort` for the full documentation

See also:**`MaskedArray.sort`**

equivalent method

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = [11.2, -3.973, 0.801, -1.41]
>>> mask = [0, 0, 0, 1]
>>> masked_x = ma.masked_array(x, mask)
>>> masked_x
masked_array(data=[11.2, -3.973, 0.801, --],
             mask=[False, False, False,  True],
             fill_value=1e+20)
>>> ma.sort(masked_x)
masked_array(data=[-3.973, 0.801, 11.2, --],
             mask=[False, False, False,  True],
             fill_value=1e+20)
```

method

`ma.MaskedArray.argsort` (*axis*=<no value>, *kind*=None, *order*=None, *endwith*=True, *fill_value*=None, *, *stable*=False, *descending*=False)

Return an ndarray of indices that sort the array along the specified axis. Masked values are filled beforehand to *fill_value*.

Parameters

axis

[int, optional] Axis along which to sort. If None, the default, the flattened array is used.

kind

[{'quicksort', 'mergesort', 'heapsort', 'stable'}, optional] The sorting algorithm used.

order

[str or list of str, optional] When *a* is an array with fields defined, this argument specifies which fields to compare first, second, etc. Not all fields need be specified.

endwith

[{True, False}, optional] Whether missing values (if any) should be treated as the largest values (True) or the smallest values (False) When the array contains unmasked values at the same extremes of the datatype, the ordering of these values and the masked values is undefined.

fill_value

[scalar or None, optional] Value used internally for the masked values. If *fill_value* is not None, it supersedes *endwith*.

stable

[bool, optional] Only for compatibility with `np.argsort`. Ignored.

descending

[bool, optional] Only for compatibility with `np.sort`. Ignored.

Returns

index_array

[ndarray, int] Array of indices that sort *a* along the specified axis. In other words, `a[index_array]` yields a sorted *a*.

See also:

[`ma.MaskedArray.sort`](#)

Describes sorting algorithms used.

lexsort

Indirect stable sort with multiple keys.

numpy.ndarray.sort

Inplace sort.

Notes

See [sort](#) for notes on the different sorting algorithms.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([3,2,1], mask=[False, False, True])
>>> a
masked_array(data=[3, 2, --],
              mask=[False, False,  True],
              fill_value=999999)
>>> a.argsort()
array([1, 0, 2])
```

method

`ma.MaskedArray.sort` (*axis=-1, kind=None, order=None, endwith=True, fill_value=None, *, stable=False, descending=False*)

Sort the array, in-place

Parameters**a**

[array_like] Array to be sorted.

axis

[int, optional] Axis along which to sort. If None, the array is flattened before sorting. The default is -1, which sorts along the last axis.

kind

[{'quicksort', 'mergesort', 'heapsort', 'stable'}, optional] The sorting algorithm used.

order

[list, optional] When *a* is a structured array, this argument specifies which fields to compare first, second, and so on. This list does not need to include all of the fields.

endwith

[{True, False}, optional] Whether missing values (if any) should be treated as the largest values (True) or the smallest values (False) When the array contains unmasked values sorting at the same extremes of the datatype, the ordering of these values and the masked values is undefined.

fill_value

[scalar or None, optional] Value used internally for the masked values. If *fill_value* is not None, it supersedes *endwith*.

stable

[bool, optional] Only for compatibility with `np.sort`. Ignored.

descending

[bool, optional] Only for compatibility with `np.sort`. Ignored.

See also:

`numpy.ndarray.sort`

Method to sort an array in-place.

`argsort`

Indirect sort.

`lexsort`

Indirect stable sort on multiple keys.

`searchsorted`

Find elements in a sorted array.

Notes

See `sort` for notes on the different sorting algorithms.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([1, 2, 5, 4, 3], mask=[0, 1, 0, 1, 0])
>>> # Default
>>> a.sort()
>>> a
masked_array(data=[1, 3, 5, --, --],
             mask=[False, False, False,  True,  True],
             fill_value=999999)
```

```
>>> a = np.ma.array([1, 2, 5, 4, 3], mask=[0, 1, 0, 1, 0])
>>> # Put missing values in the front
>>> a.sort(endwith=False)
>>> a
masked_array(data=[--, --, 1, 3, 5],
             mask=[ True,  True, False, False, False],
             fill_value=999999)
```

```
>>> a = np.ma.array([1, 2, 5, 4, 3], mask=[0, 1, 0, 1, 0])
>>> # fill_value takes over endwith
>>> a.sort(endwith=False, fill_value=3)
>>> a
masked_array(data=[1, --, --, 3, 5],
             mask=[False,  True,  True, False, False],
             fill_value=999999)
```

Algebra

<code>ma.diag(v[, k])</code>	Extract a diagonal or construct a diagonal array.
<code>ma.dot(a, b[, strict, out])</code>	Return the dot product of two arrays.
<code>ma.identity(n[, dtype, like, fill_value, ...])</code>	Return the identity array.
<code>ma.inner(a, b, /)</code>	Inner product of two arrays.
<code>ma.innerproduct(a, b, /)</code>	Inner product of two arrays.
<code>ma.outer(a, b)</code>	Compute the outer product of two vectors.
<code>ma.outerproduct(a, b)</code>	Compute the outer product of two vectors.
<code>ma.trace(a.trace)</code>	Return the sum along diagonals of the array.
<code>ma.transpose(a[, axes])</code>	Permute the dimensions of an array.
<code>ma.MaskedArray.trace([offset, axis1, axis2, ...])</code>	Return the sum along diagonals of the array.
<code>ma.MaskedArray.transpose(*axes)</code>	Returns a view of the array with axes transposed.

`ma.diag (v, k=0)`

Extract a diagonal or construct a diagonal array.

This function is the equivalent of `numpy.diag` that takes masked values into account, see `numpy.diag` for details.

See also:

`numpy.diag`

Equivalent function for ndarrays.

Examples

```
>>> import numpy as np
```

Create an array with negative values masked:

```
>>> import numpy as np
>>> x = np.array([[11.2, -3.973, 18], [0.801, -1.41, 12], [7, 33, -12]])
>>> masked_x = np.ma.masked_array(x, mask=x < 0)
>>> masked_x
masked_array(
  data=[[11.2, --, 18.0],
        [0.801, --, 12.0],
        [7.0, 33.0, --]],
  mask=[[False,  True, False],
        [False,  True, False],
        [False, False,  True]],
  fill_value=1e+20)
```

Isolate the main diagonal from the masked array:

```
>>> np.ma.diag(masked_x)
masked_array(data=[11.2, --, --],
             mask=[False,  True,  True],
             fill_value=1e+20)
```

Isolate the first diagonal below the main diagonal:

```
>>> np.ma.diag(masked_x, -1)
masked_array(data=[0.801, 33.0],
              mask=[False, False],
              fill_value=1e+20)
```

`ma.dot(a, b, strict=False, out=None)`

Return the dot product of two arrays.

This function is the equivalent of `numpy.dot` that takes masked values into account. Note that `strict` and `out` are in different position than in the method version. In order to maintain compatibility with the corresponding method, it is recommended that the optional arguments be treated as keyword only. At some point that may be mandatory.

Parameters

a, b

[masked_array_like] Inputs arrays.

strict

[bool, optional] Whether masked data are propagated (True) or set to 0 (False) for the computation. Default is False. Propagating the mask means that if a masked value appears in a row or column, the whole row or column is considered masked.

out

[masked_array, optional] Output argument. This must have the exact kind that would be returned if it was not used. In particular, it must have the right type, must be C-contiguous, and its dtype must be the dtype that would be returned for `dot(a,b)`. This is a performance feature. Therefore, if these conditions are not met, an exception is raised, instead of attempting to be flexible.

See also:

`numpy.dot`

Equivalent function for ndarrays.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([[1, 2, 3], [4, 5, 6]], mask=[[1, 0, 0], [0, 0, 0]])
>>> b = np.ma.array([[1, 2], [3, 4], [5, 6]], mask=[[1, 0], [0, 0], [0, 0]])
>>> np.ma.dot(a, b)
masked_array(
  data=[[21, 26],
        [45, 64]],
  mask=[[False, False],
        [False, False]],
  fill_value=999999)
>>> np.ma.dot(a, b, strict=True)
masked_array(
  data=[[--, --],
        [--, 64]],
  mask=[[ True,  True],
        [ True, False]],
  fill_value=999999)
```

`ma.identity(n, dtype=None, *, like=None, fill_value=None, hardmask=False)`

Return the identity array.

The identity array is a square array with ones on the main diagonal.

Parameters

n

[int] Number of rows (and columns) in $n \times n$ output.

dtype

[data-type, optional] Data-type of the output. Defaults to `float`.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[MaskedArray] $n \times n$ array with its main diagonal set to one, and all other elements 0.

Examples

```
>>> import numpy as np
>>> np.identity(3)
array([[1.,  0.,  0.],
       [0.,  1.,  0.],
       [0.,  0.,  1.]])
```

`ma.inner(a, b, /)`

Inner product of two arrays.

Ordinary inner product of vectors for 1-D arrays (without complex conjugation), in higher dimensions a sum product over the last axes.

Parameters

a, b

[array_like] If *a* and *b* are nonscalar, their last dimensions must match.

Returns

out

[ndarray] If *a* and *b* are both scalars or both 1-D arrays then a scalar is returned; otherwise an array is returned. `out.shape = (*a.shape[:-1], *b.shape[:-1])`

Raises

ValueError

If both *a* and *b* are nonscalar and their last dimensions have different sizes.

See also:

[*tensor.dot*](#)

Sum products over arbitrary axes.

[*dot*](#)

Generalised matrix product, using second last dimension of *b*.

vecdot

Vector dot product of two arrays.

einsum

Einstein summation convention.

Notes

Masked values are replaced by 0.

For vectors (1-D arrays) it computes the ordinary inner-product:

```
np.inner(a, b) = sum(a[:] * b[:])
```

More generally, if $\text{ndim}(a) = r > 0$ and $\text{ndim}(b) = s > 0$:

```
np.inner(a, b) = np.tensordot(a, b, axes=(-1,-1))
```

or explicitly:

```
np.inner(a, b)[i0,...,ir-2,j0,...,js-2]  
    = sum(a[i0,...,ir-2,:]*b[j0,...,js-2,:])
```

In addition a or b may be scalars, in which case:

```
np.inner(a,b) = a*b
```

Examples

Ordinary inner product for vectors:

```
>>> import numpy as np  
>>> a = np.array([1,2,3])  
>>> b = np.array([0,1,0])  
>>> np.inner(a, b)  
2
```

Some multidimensional examples:

```
>>> a = np.arange(24).reshape((2,3,4))  
>>> b = np.arange(4)  
>>> c = np.inner(a, b)  
>>> c.shape  
(2, 3)  
>>> c  
array([[ 14,  38,  62],  
       [ 86, 110, 134]])
```

```
>>> a = np.arange(2).reshape((1,1,2))  
>>> b = np.arange(6).reshape((3,2))  
>>> c = np.inner(a, b)  
>>> c.shape  
(1, 1, 3)  
>>> c  
array([[[1, 3, 5]]])
```

An example where b is a scalar:

```
>>> np.inner(np.eye(2), 7)
array([[7., 0.],
       [0., 7.]])
```

ma.**innerproduct** ($a, b, /$)

Inner product of two arrays.

Ordinary inner product of vectors for 1-D arrays (without complex conjugation), in higher dimensions a sum product over the last axes.

Parameters

a, b

[array_like] If a and b are nonscalar, their last dimensions must match.

Returns

out

[ndarray] If a and b are both scalars or both 1-D arrays then a scalar is returned; otherwise an array is returned. `out.shape = (*a.shape[:-1], *b.shape[:-1])`

Raises

ValueError

If both a and b are nonscalar and their last dimensions have different sizes.

See also:

[*tensor_dot*](#)

Sum products over arbitrary axes.

[*dot*](#)

Generalised matrix product, using second last dimension of b .

[*vecdot*](#)

Vector dot product of two arrays.

[*einsum*](#)

Einstein summation convention.

Notes

Masked values are replaced by 0.

For vectors (1-D arrays) it computes the ordinary inner-product:

```
np.inner(a, b) = sum(a[:] * b[:])
```

More generally, if `ndim(a) = r > 0` and `ndim(b) = s > 0`:

```
np.inner(a, b) = np.tensor_dot(a, b, axes=(-1, -1))
```

or explicitly:

```
np.inner(a, b)[i0, ..., ir-2, j0, ..., js-2]
    = sum(a[i0, ..., ir-2, :] * b[j0, ..., js-2, :])
```

In addition a or b may be scalars, in which case:

```
np.inner(a,b) = a*b
```

Examples

Ordinary inner product for vectors:

```
>>> import numpy as np
>>> a = np.array([1,2,3])
>>> b = np.array([0,1,0])
>>> np.inner(a, b)
2
```

Some multidimensional examples:

```
>>> a = np.arange(24).reshape((2,3,4))
>>> b = np.arange(4)
>>> c = np.inner(a, b)
>>> c.shape
(2, 3)
>>> c
array([[ 14,  38,  62],
       [ 86, 110, 134]])
```

```
>>> a = np.arange(2).reshape((1,1,2))
>>> b = np.arange(6).reshape((3,2))
>>> c = np.inner(a, b)
>>> c.shape
(1, 1, 3)
>>> c
array([[[1, 3, 5]]])
```

An example where *b* is a scalar:

```
>>> np.inner(np.eye(2), 7)
array([[7., 0.],
       [0., 7.]])
```

`ma.outer(a,b)`

Compute the outer product of two vectors.

Given two vectors *a* and *b* of length *M* and *N*, respectively, the outer product [1] is:

```
[ [a_0*b_0  a_0*b_1  ...  a_0*b_{N-1} ]
  [a_1*b_0      .
  [ ...          .
  [a_{M-1}*b_0      a_{M-1}*b_{N-1} ]]
```

Parameters

a

[(*M*,) array_like] First input vector. Input is flattened if not already 1-dimensional.

b

[(*N*,) array_like] Second input vector. Input is flattened if not already 1-dimensional.

out
[(M, N) ndarray, optional] A location where the result is stored

Returns

out
[(M, N) ndarray] `out[i, j] = a[i] * b[j]`

See also:

inner

einsum

`einsum('i,j->ij', a.ravel(), b.ravel())` is the equivalent.

ufunc.outer

A generalization to dimensions other than 1D and other operations. `np.multiply.outer(a.ravel(), b.ravel())` is the equivalent.

linalg.outer

An Array API compatible variation of `np.outer`, which accepts 1-dimensional inputs only.

tensordot

`np.tensordot(a.ravel(), b.ravel(), axes=(), ())` is the equivalent.

Notes

Masked values are replaced by 0.

[1]

Examples

Make a (very coarse) grid for computing a Mandelbrot set:

```
>>> import numpy as np
>>> rl = np.outer(np.ones((5,)), np.linspace(-2, 2, 5))
>>> rl
array([[ -2.,  -1.,   0.,   1.,   2.],
       [ -2.,  -1.,   0.,   1.,   2.],
       [ -2.,  -1.,   0.,   1.,   2.],
       [ -2.,  -1.,   0.,   1.,   2.],
       [ -2.,  -1.,   0.,   1.,   2.]])
>>> im = np.outer(1j*np.linspace(2, -2, 5), np.ones((5,)))
>>> im
array([[ 0.+2.j,  0.+2.j,  0.+2.j,  0.+2.j,  0.+2.j],
       [ 0.+1.j,  0.+1.j,  0.+1.j,  0.+1.j,  0.+1.j],
       [ 0.+0.j,  0.+0.j,  0.+0.j,  0.+0.j,  0.+0.j],
       [ 0.-1.j,  0.-1.j,  0.-1.j,  0.-1.j,  0.-1.j],
       [ 0.-2.j,  0.-2.j,  0.-2.j,  0.-2.j,  0.-2.j]])
>>> grid = rl + im
>>> grid
array([[ -2.+2.j,  -1.+2.j,   0.+2.j,   1.+2.j,   2.+2.j],
       [ -2.+1.j,  -1.+1.j,   0.+1.j,   1.+1.j,   2.+1.j],
```

(continues on next page)

(continued from previous page)

```
[-2.+0.j, -1.+0.j,  0.+0.j,  1.+0.j,  2.+0.j],
[-2.-1.j, -1.-1.j,  0.-1.j,  1.-1.j,  2.-1.j],
[-2.-2.j, -1.-2.j,  0.-2.j,  1.-2.j,  2.-2.j]])
```

An example using a “vector” of letters:

```
>>> x = np.array(['a', 'b', 'c'], dtype=np.object_)
>>> np.outer(x, [1, 2, 3])
array([[ 'a', 'aa', 'aaa'],
       [ 'b', 'bb', 'bbb'],
       [ 'c', 'cc', 'ccc']], dtype=object)
```

ma.outerproduct (*a*, *b*)

Compute the outer product of two vectors.

Given two vectors *a* and *b* of length *M* and *N*, respectively, the outer product [1] is:

```
[ [a_0*b_0  a_0*b_1  ...  a_0*b_{N-1} ]
  [a_1*b_0      .
  [ ...      .
  [a_{M-1}*b_0      a_{M-1}*b_{N-1} ]]
```

Parameters

a

[(*M*,) array_like] First input vector. Input is flattened if not already 1-dimensional.

b

[(*N*,) array_like] Second input vector. Input is flattened if not already 1-dimensional.

out

[(*M*, *N*) ndarray, optional] A location where the result is stored

Returns

out

[(*M*, *N*) ndarray] `out[i, j] = a[i] * b[j]`

See also:

inner

einsum

`einsum('i,j->ij', a.ravel(), b.ravel())` is the equivalent.

ufunc.outer

A generalization to dimensions other than 1D and other operations. `np.multiply.outer(a.ravel(), b.ravel())` is the equivalent.

linalg.outer

An Array API compatible variation of `np.outer`, which accepts 1-dimensional inputs only.

tensordot

`np.tensordot(a.ravel(), b.ravel(), axes=(), ())` is the equivalent.

Notes

Masked values are replaced by 0.

Examples

Make a (very coarse) grid for computing a Mandelbrot set:

```
>>> import numpy as np
>>> rl = np.outer(np.ones((5,)), np.linspace(-2, 2, 5))
>>> rl
array([[ -2.,  -1.,   0.,   1.,   2.],
       [ -2.,  -1.,   0.,   1.,   2.],
       [ -2.,  -1.,   0.,   1.,   2.],
       [ -2.,  -1.,   0.,   1.,   2.],
       [ -2.,  -1.,   0.,   1.,   2.]])
>>> im = np.outer(1j*np.linspace(2, -2, 5), np.ones((5,)))
>>> im
array([[ 0.+2.j,  0.+2.j,  0.+2.j,  0.+2.j,  0.+2.j],
       [ 0.+1.j,  0.+1.j,  0.+1.j,  0.+1.j,  0.+1.j],
       [ 0.+0.j,  0.+0.j,  0.+0.j,  0.+0.j,  0.+0.j],
       [ 0.-1.j,  0.-1.j,  0.-1.j,  0.-1.j,  0.-1.j],
       [ 0.-2.j,  0.-2.j,  0.-2.j,  0.-2.j,  0.-2.j]])
>>> grid = rl + im
>>> grid
array([[ -2.+2.j,  -1.+2.j,   0.+2.j,   1.+2.j,   2.+2.j],
       [ -2.+1.j,  -1.+1.j,   0.+1.j,   1.+1.j,   2.+1.j],
       [ -2.+0.j,  -1.+0.j,   0.+0.j,   1.+0.j,   2.+0.j],
       [ -2.-1.j,  -1.-1.j,   0.-1.j,   1.-1.j,   2.-1.j],
       [ -2.-2.j,  -1.-2.j,   0.-2.j,   1.-2.j,   2.-2.j]])
```

An example using a “vector” of letters:

```
>>> x = np.array(['a', 'b', 'c'], dtype=np.object_)
>>> np.outer(x, [1, 2, 3])
array([[ 'a',  'aa',  'aaa'],
       [ 'b',  'bb',  'bbb'],
       [ 'c',  'cc',  'ccc']], dtype=object)
```

ma.**trace** (*self*, *offset*=0, *axis1*=0, *axis2*=1, *dtype*=None, *out*=None) a.**trace**(*offset*=0, *axis1*=0, *axis2*=1, *dtype*=None, *out*=None)

ma.**trace** (*offset*=0, *axis1*=0, *axis2*=1, *dtype*=None, *out*=None) → None

Return the sum along diagonals of the array.

Refer to [numpy.trace](#) for full documentation.

See also:

[numpy.trace](#)

equivalent function

method

`ma.MaskedArray.trace` (*offset=0, axis1=0, axis2=1, dtype=None, out=None*)

Return the sum along diagonals of the array.

Refer to [`numpy.trace`](#) for full documentation.

See also:

[`numpy.trace`](#)

equivalent function

Polynomial fit

<code>ma.vander</code> (<i>x</i> [, <i>n</i>])	Generate a Vandermonde matrix.
<code>ma.polyfit</code> (<i>x</i> , <i>y</i> , <i>deg</i> [, <i>rcond</i> , <i>full</i> , <i>w</i> , <i>cov</i>])	Least squares polynomial fit.

`ma.vander` (*x*, *n=None*)

Generate a Vandermonde matrix.

The columns of the output matrix are powers of the input vector. The order of the powers is determined by the *increasing* boolean argument. Specifically, when *increasing* is False, the *i*-th output column is the input vector raised element-wise to the power of $N - i - 1$. Such a matrix with a geometric progression in each row is named for Alexandre- Theophile Vandermonde.

Parameters

x

[array_like] 1-D input array.

N

[int, optional] Number of columns in the output. If *N* is not specified, a square array is returned ($N = \text{len}(x)$).

increasing

[bool, optional] Order of the powers of the columns. If True, the powers increase from left to right, if False (the default) they are reversed.

Returns

out

[ndarray] Vandermonde matrix. If *increasing* is False, the first column is $x^{(N-1)}$, the second $x^{(N-2)}$ and so forth. If *increasing* is True, the columns are x^0 , x^1 , ..., $x^{(N-1)}$.

See also:

[`polynomial.polynomial.polyvander`](#)

Notes

Masked values in the input array result in rows of zeros.

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 3, 5])
>>> N = 3
>>> np.vander(x, N)
array([[ 1,  1,  1],
       [ 4,  2,  1],
       [ 9,  3,  1],
       [25,  5,  1]])
```

```
>>> np.column_stack([x**(N-1-i) for i in range(N)])
array([[ 1,  1,  1],
       [ 4,  2,  1],
       [ 9,  3,  1],
       [25,  5,  1]])
```

```
>>> x = np.array([1, 2, 3, 5])
>>> np.vander(x)
array([[ 1,  1,  1,  1],
       [ 8,  4,  2,  1],
       [27,  9,  3,  1],
       [125, 25,  5,  1]])
>>> np.vander(x, increasing=True)
array([[ 1,  1,  1,  1],
       [ 1,  2,  4,  8],
       [ 1,  3,  9, 27],
       [ 1,  5, 25, 125]])
```

The determinant of a square Vandermonde matrix is the product of the differences between the values of the input vector:

```
>>> np.linalg.det(np.vander(x))
48.0000000000000043 # may vary
>>> (5-3)*(5-2)*(5-1)*(3-2)*(3-1)*(2-1)
48
```

`ma.polyfit(x, y, deg, rcond=None, full=False, w=None, cov=False)`

Least squares polynomial fit.

Note: This forms part of the old polynomial API. Since version 1.4, the new polynomial API defined in `numpy.polynomial` is preferred. A summary of the differences can be found in the [transition guide](#).

Fit a polynomial $p[0] * x^{deg} + \dots + p[deg]$ of degree *deg* to points (*x*, *y*). Returns a vector of coefficients *p* that minimises the squared error in the order *deg*, *deg*-1, ... 0.

The `Polynomial.fit` class method is recommended for new code as it is more stable numerically. See the documentation of the method for more information.

Parameters

x

[array_like, shape (M,)] x-coordinates of the M sample points ($x[i]$, $y[i]$).

y

[array_like, shape (M,) or (M, K)] y-coordinates of the sample points. Several data sets of sample points sharing the same x-coordinates can be fitted at once by passing in a 2D-array that contains one dataset per column.

deg

[int] Degree of the fitting polynomial

rcond

[float, optional] Relative condition number of the fit. Singular values smaller than this relative to the largest singular value will be ignored. The default value is $\text{len}(x)*\text{eps}$, where eps is the relative precision of the float type, about $2e-16$ in most cases.

full

[bool, optional] Switch determining nature of return value. When it is False (the default) just the coefficients are returned, when True diagnostic information from the singular value decomposition is also returned.

w

[array_like, shape (M,), optional] Weights. If not None, the weight $w[i]$ applies to the unsquared residual $y[i] - \hat{y}[i]$ at $x[i]$. Ideally the weights are chosen so that the errors of the products $w[i]*y[i]$ all have the same variance. When using inverse-variance weighting, use $w[i] = 1/\text{sigma}(y[i])$. The default value is None.

cov

[bool or str, optional] If given and not *False*, return not just the estimate but also its covariance matrix. By default, the covariance are scaled by $\text{chi2}/\text{dof}$, where $\text{dof} = M - (\text{deg} + 1)$, i.e., the weights are presumed to be unreliable except in a relative sense and everything is scaled such that the reduced chi2 is unity. This scaling is omitted if `cov='unscaled'`, as is relevant for the case that the weights are $w = 1/\text{sigma}$, with sigma known to be a reliable estimate of the uncertainty.

Returns

p

[ndarray, shape (deg + 1,) or (deg + 1, K)] Polynomial coefficients, highest power first. If y was 2-D, the coefficients for k -th data set are in $p[:, k]$.

residuals, rank, singular_values, rcond

These values are only returned if `full == True`

- residuals – sum of squared residuals of the least squares fit
- rank – the effective rank of the scaled Vandermonde coefficient matrix
- singular_values – singular values of the scaled Vandermonde coefficient matrix
- rcond – value of *rcond*.

For more details, see [numpy.linalg.lstsq](#).

V

[ndarray, shape (deg + 1, deg + 1) or (deg + 1, deg + 1, K)] Present only if `full == False` and `cov == True`. The covariance matrix of the polynomial coefficient estimates. The diagonal of this matrix are the variance estimates for each coefficient. If y is a 2-D array, then the covariance matrix for the k -th data set are in $V[:, :, k]$

Warns

RankWarning

The rank of the coefficient matrix in the least-squares fit is deficient. The warning is only raised if `full == False`.

The warnings can be turned off by

```
>>> import warnings
>>> warnings.simplefilter('ignore', np.exceptions.RankWarning)
```

See also:

[`polyval`](#)

Compute polynomial values.

[`linalg.lstsq`](#)

Computes a least-squares fit.

[`scipy.interpolate.UnivariateSpline`](#)

Computes spline fits.

Notes

Any masked values in `x` is propagated in `y`, and vice-versa.

The solution minimizes the squared error

$$E = \sum_{j=0}^k |p(x_j) - y_j|^2$$

in the equations:

```
x[0]**n * p[0] + ... + x[0] * p[n-1] + p[n] = y[0]
x[1]**n * p[0] + ... + x[1] * p[n-1] + p[n] = y[1]
...
x[k]**n * p[0] + ... + x[k] * p[n-1] + p[n] = y[k]
```

The coefficient matrix of the coefficients p is a Vandermonde matrix.

`polyfit` issues a [`RankWarning`](#) when the least-squares fit is badly conditioned. This implies that the best fit is not well-defined due to numerical error. The results may be improved by lowering the polynomial degree or by replacing `x` by `x - x.mean()`. The `rcond` parameter can also be set to a value smaller than its default, but the resulting fit may be spurious: including contributions from the small singular values can add numerical noise to the result.

Note that fitting polynomial coefficients is inherently badly conditioned when the degree of the polynomial is large or the interval of sample points is badly centered. The quality of the fit should always be checked in these cases. When polynomial fits are not satisfactory, splines may be a good alternative.

References

[1], [2]

Examples

```
>>> import numpy as np
>>> import warnings
>>> x = np.array([0.0, 1.0, 2.0, 3.0, 4.0, 5.0])
>>> y = np.array([0.0, 0.8, 0.9, 0.1, -0.8, -1.0])
>>> z = np.polyfit(x, y, 3)
>>> z
array([ 0.08703704, -0.81349206,  1.69312169, -0.03968254]) # may vary
```

It is convenient to use *poly1d* objects for dealing with polynomials:

```
>>> p = np.poly1d(z)
>>> p(0.5)
0.6143849206349179 # may vary
>>> p(3.5)
-0.34732142857143039 # may vary
>>> p(10)
22.579365079365115 # may vary
```

High-order polynomials may oscillate wildly:

```
>>> with warnings.catch_warnings():
...     warnings.simplefilter('ignore', np.exceptions.RankWarning)
...     p30 = np.poly1d(np.polyfit(x, y, 30))
...
>>> p30(4)
-0.800000000000000204 # may vary
>>> p30(5)
-0.999999999999999445 # may vary
>>> p30(4.5)
-0.10547061179440398 # may vary
```

Illustration:

```
>>> import matplotlib.pyplot as plt
>>> xp = np.linspace(-2, 6, 100)
>>> _ = plt.plot(x, y, '.', xp, p(xp), '-', xp, p30(xp), '--')
>>> plt.ylim(-2, 2)
(-2, 2)
>>> plt.show()
```

Clipping and rounding

<i>ma.around</i>	Round an array to the given number of decimals.
<i>ma.clip</i> (a[, a_min, a_max, out, min, max, ...])	Clip (limit) the values in an array.
<i>ma.round</i> (a[, decimals, out])	Return a copy of a, rounded to 'decimals' places.
<i>ma.MaskedArray.clip</i> ([min, max, out])	Return an array whose values are limited to [min, max].
<i>ma.MaskedArray.round</i> ([decimals, out])	Return each element rounded to the given number of decimals.

`ma.around` = `<numpy.ma.core._MaskedUnaryOperation object>`

Round an array to the given number of decimals.

`around` is an alias of `round`.

See also:

`ndarray.round`

equivalent method

`round`

alias for this function

`ceil`, `fix`, `floor`, `rint`, `trunc`

`ma.clip` (`a`, `a_min=<no value>`, `a_max=<no value>`, `out=None`, `*`, `min=<no value>`, `max=<no value>`, `fill_value=None`, `hardmask=False`, `**kwargs`)

Clip (limit) the values in an array.

Given an interval, values outside the interval are clipped to the interval edges. For example, if an interval of `[0, 1]` is specified, values smaller than 0 become 0, and values larger than 1 become 1.

Equivalent to but faster than `np.minimum(a_max, np.maximum(a, a_min))`.

No check is performed to ensure `a_min < a_max`.

Parameters

a

[array_like] Array containing elements to clip.

a_min, a_max

[array_like or None] Minimum and maximum value. If `None`, clipping is not performed on the corresponding edge. If both `a_min` and `a_max` are `None`, the elements of the returned array stay the same. Both are broadcasted against `a`.

out

[ndarray, optional] The results will be placed in this array. It may be the input array for in-place clipping. `out` must be of the right shape to hold the output. Its type is preserved.

min, max

[array_like or None] Array API compatible alternatives for `a_min` and `a_max` arguments. Either `a_min` and `a_max` or `min` and `max` can be passed at the same time. Default: `None`.

New in version 2.1.0.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**clipped_array**

[MaskedArray] An array with the elements of `a`, but where values $< a_{\min}$ are replaced with `a_min`, and those $> a_{\max}$ with `a_max`.

See also:

ufuncs-output-type

Notes

When `a_min` is greater than `a_max`, `clip` returns an array in which all values are equal to `a_max`, as shown in the second example.

Examples

```
>>> import numpy as np
>>> a = np.arange(10)
>>> a
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> np.clip(a, 1, 8)
array([1, 1, 2, 3, 4, 5, 6, 7, 8, 8])
>>> np.clip(a, 8, 1)
array([1, 1, 1, 1, 1, 1, 1, 1, 1, 1])
>>> np.clip(a, 3, 6, out=a)
array([3, 3, 3, 3, 4, 5, 6, 6, 6, 6])
>>> a
array([3, 3, 3, 3, 4, 5, 6, 6, 6, 6])
>>> a = np.arange(10)
>>> a
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> np.clip(a, [3, 4, 1, 1, 1, 4, 4, 4, 4, 4], 8)
array([3, 4, 2, 3, 4, 5, 6, 7, 8, 8])
```

`ma.round(a, decimals=0, out=None)`

Return a copy of `a`, rounded to ‘decimals’ places.

When ‘decimals’ is negative, it specifies the number of positions to the left of the decimal point. The real and imaginary parts of complex numbers are rounded separately. Nothing is done if the array is not of float type and ‘decimals’ is greater than or equal to 0.

Parameters**decimals**

[int] Number of decimals to round to. May be negative.

out

[array_like] Existing array to use for output. If not given, returns a default copy of `a`.

Notes

If out is given and does not have a mask attribute, the mask of a is lost!

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = [11.2, -3.973, 0.801, -1.41]
>>> mask = [0, 0, 0, 1]
>>> masked_x = ma.masked_array(x, mask)
>>> masked_x
masked_array(data=[11.2, -3.973, 0.801, --],
             mask=[False, False, False, True],
             fill_value=1e+20)
>>> ma.round(masked_x)
masked_array(data=[11.0, -4.0, 1.0, --],
             mask=[False, False, False, True],
             fill_value=1e+20)
>>> ma.round(masked_x, decimals=1)
masked_array(data=[11.2, -4.0, 0.8, --],
             mask=[False, False, False, True],
             fill_value=1e+20)
>>> ma.round(masked_x, decimals=-1)
masked_array(data=[10.0, -0.0, 0.0, --],
             mask=[False, False, False, True],
             fill_value=1e+20)
```

method

`ma.MaskedArray.clip` (*min=<no value>*, *max=<no value>*, *out=None*, ***kwargs*)

Return an array whose values are limited to `[min, max]`. One of `max` or `min` must be given.

Refer to [`numpy.clip`](#) for full documentation.

See also:

[`numpy.clip`](#)

equivalent function

method

`ma.MaskedArray.round` (*decimals=0*, *out=None*)

Return each element rounded to the given number of decimals.

Refer to [`numpy.around`](#) for full documentation.

See also:

[`numpy.ndarray.round`](#)

corresponding function for ndarrays

[`numpy.around`](#)

equivalent function

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = ma.array([1.35, 2.5, 1.5, 1.75, 2.25, 2.75],
...              mask=[0, 0, 0, 1, 0, 0])
>>> ma.round(x)
masked_array(data=[1.0, 2.0, 2.0, --, 2.0, 3.0],
             mask=[False, False, False,  True, False, False],
             fill_value=1e+20)
```

Set operations

<code>ma.intersect1d(ar1, ar2[, assume_unique])</code>	Returns the unique elements common to both arrays.
<code>ma.setdiff1d(ar1, ar2[, assume_unique])</code>	Set difference of 1D arrays with unique elements.
<code>ma.setxor1d(ar1, ar2[, assume_unique])</code>	Set exclusive-or of 1-D arrays with unique elements.
<code>ma.union1d(ar1, ar2)</code>	Union of two arrays.

`ma.intersect1d(ar1, ar2, assume_unique=False)`

Returns the unique elements common to both arrays.

Masked values are considered equal one to the other. The output is always a masked array.

See [`numpy.intersect1d`](#) for more details.

See also:

[`numpy.intersect1d`](#)

Equivalent function for ndarrays.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([1, 3, 3, 3], mask=[0, 0, 0, 1])
>>> y = np.ma.array([3, 1, 1, 1], mask=[0, 0, 0, 1])
>>> np.ma.intersect1d(x, y)
masked_array(data=[1, 3, --],
             mask=[False, False,  True],
             fill_value=999999)
```

`ma.setdiff1d(ar1, ar2, assume_unique=False)`

Set difference of 1D arrays with unique elements.

The output is always a masked array. See [`numpy.setdiff1d`](#) for more details.

See also:

[`numpy.setdiff1d`](#)

Equivalent function for ndarrays.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([1, 2, 3, 4], mask=[0, 1, 0, 1])
>>> np.ma.setdiff1d(x, [1, 2])
masked_array(data=[3, --],
              mask=[False,  True],
              fill_value=999999)
```

`ma.setxor1d(ar1, ar2, assume_unique=False)`

Set exclusive-or of 1-D arrays with unique elements.

The output is always a masked array. See [numpy.setxor1d](#) for more details.

See also:

[numpy.setxor1d](#)

Equivalent function for ndarrays.

Examples

```
>>> import numpy as np
>>> ar1 = np.ma.array([1, 2, 3, 2, 4])
>>> ar2 = np.ma.array([2, 3, 5, 7, 5])
>>> np.ma.setxor1d(ar1, ar2)
masked_array(data=[1, 4, 5, 7],
              mask=False,
              fill_value=999999)
```

`ma.union1d(ar1, ar2)`

Union of two arrays.

The output is always a masked array. See [numpy.union1d](#) for more details.

See also:

[numpy.union1d](#)

Equivalent function for ndarrays.

Examples

```
>>> import numpy as np
>>> ar1 = np.ma.array([1, 2, 3, 4])
>>> ar2 = np.ma.array([3, 4, 5, 6])
>>> np.ma.union1d(ar1, ar2)
masked_array(data=[1, 2, 3, 4, 5, 6],
              mask=False,
              fill_value=999999)
```

Miscellanea

<code>ma.allequal(a, b[, fill_value])</code>	Return True if all entries of a and b are equal, using fill_value as a truth value where either or both are masked.
<code>ma.allclose(a, b[, masked_equal, rtol, atol])</code>	Returns True if two arrays are element-wise equal within a tolerance.
<code>ma.amax(a[, axis, out, keepdims, initial, where])</code>	Return the maximum of an array or maximum along an axis.
<code>ma.amin(a[, axis, out, keepdims, initial, where])</code>	Return the minimum of an array or minimum along an axis.
<code>ma.apply_along_axis(func1d, axis, arr, ...)</code>	Apply a function to 1-D slices along the given axis.
<code>ma.apply_over_axes(func, a, axes)</code>	Apply a function repeatedly over multiple axes.
<code>ma.arange([start,] stop[, step,][, dtype, ...])</code>	Return evenly spaced values within a given interval.
<code>ma.choose(indices, choices[, out, mode])</code>	Use an index array to construct a new array from a list of choices.
<code>ma.compress_nd(x[, axis])</code>	Suppress slices from multiple dimensions which contain masked values.
<code>ma.convolve(a, v[, mode, propagate_mask])</code>	Returns the discrete, linear convolution of two one-dimensional sequences.
<code>ma.correlate(a, v[, mode, propagate_mask])</code>	Cross-correlation of two 1-dimensional sequences.
<code>ma.ediff1d(arr[, to_end, to_begin])</code>	Compute the differences between consecutive elements of an array.
<code>ma.flatten_mask(mask)</code>	Returns a completely flattened version of the mask, where nested fields are collapsed.
<code>ma.flatten_structured_array(a)</code>	Flatten a structured array.
<code>ma.fromflex(fxarray)</code>	Build a masked array from a suitable flexible-type array.
<code>ma.indices(dimensions[, dtype, sparse, ...])</code>	Return an array representing the indices of a grid.
<code>ma.left_shift(a, n)</code>	Shift the bits of an integer to the left.
<code>ma.ndim(obj)</code>	Return the number of dimensions of an array.
<code>ma.put(a, indices, values[, mode])</code>	Set storage-indexed locations to corresponding values.
<code>ma.putmask(a, mask, values)</code>	Changes elements of an array based on conditional and input values.
<code>ma.right_shift(a, n)</code>	Shift the bits of an integer to the right.
<code>ma.round_(a[, decimals, out])</code>	Return a copy of a, rounded to 'decimals' places.
<code>ma.take(a, indices[, axis, out, mode])</code>	
<code>ma.where(condition[, x, y])</code>	Return a masked array with elements from x or y, depending on condition.

`ma.allequal(a, b, fill_value=True)`

Return True if all entries of a and b are equal, using fill_value as a truth value where either or both are masked.

Parameters**a, b**

[array_like] Input arrays to compare.

fill_value

[bool, optional] Whether masked values in a or b are considered equal (True) or not (False).

Returns**y**

[bool] Returns True if the two arrays are equal within the given tolerance, False otherwise. If either array contains NaN, then False is returned.

See also:

[*all*](#), [*any*](#)
[*numpy.ma.allclose*](#)

Examples

```
>>> import numpy as np
>>> a = np.ma.array([1e10, 1e-7, 42.0], mask=[0, 0, 1])
>>> a
masked_array(data=[10000000000.0, 1e-07, --],
             mask=[False, False,  True],
             fill_value=1e+20)
```

```
>>> b = np.array([1e10, 1e-7, -42.0])
>>> b
array([ 1.00000000e+10,  1.00000000e-07, -4.20000000e+01])
>>> np.ma.allegual(a, b, fill_value=False)
False
>>> np.ma.allegual(a, b)
True
```

`ma.allclose(a, b, masked_equal=True, rtol=1e-05, atol=1e-08)`

Returns True if two arrays are element-wise equal within a tolerance.

This function is equivalent to [*allclose*](#) except that masked values are treated as equal (default) or unequal, depending on the [*masked_equal*](#) argument.

Parameters

a, b

[array_like] Input arrays to compare.

masked_equal

[bool, optional] Whether masked values in *a* and *b* are considered equal (True) or not (False). They are considered equal by default.

rtol

[float, optional] Relative tolerance. The relative difference is equal to `rtol * b`. Default is 1e-5.

atol

[float, optional] Absolute tolerance. The absolute difference is equal to `atol`. Default is 1e-8.

Returns

y

[bool] Returns True if the two arrays are equal within the given tolerance, False otherwise. If either array contains NaN, then False is returned.

See also:

[*all*](#), [*any*](#)
[*numpy.allclose*](#)
the non-masked [*allclose*](#).

Notes

If the following equation is element-wise True, then `allclose` returns True:

```
absolute(`a` - `b`) <= (`atol` + `rtol` * absolute(`b`))
```

Return True if all elements of *a* and *b* are equal subject to given tolerances.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([1e10, 1e-7, 42.0], mask=[0, 0, 1])
>>> a
masked_array(data=[10000000000.0, 1e-07, --],
             mask=[False, False, True],
             fill_value=1e+20)
>>> b = np.ma.array([1e10, 1e-8, -42.0], mask=[0, 0, 1])
>>> np.ma.allclose(a, b)
False
```

```
>>> a = np.ma.array([1e10, 1e-8, 42.0], mask=[0, 0, 1])
>>> b = np.ma.array([1.00001e10, 1e-9, -42.0], mask=[0, 0, 1])
>>> np.ma.allclose(a, b)
True
>>> np.ma.allclose(a, b, masked_equal=False)
False
```

Masked values are not compared directly.

```
>>> a = np.ma.array([1e10, 1e-8, 42.0], mask=[0, 0, 1])
>>> b = np.ma.array([1.00001e10, 1e-9, 42.0], mask=[0, 0, 1])
>>> np.ma.allclose(a, b)
True
>>> np.ma.allclose(a, b, masked_equal=False)
False
```

`ma.amax` (*a*, *axis=None*, *out=None*, *keepdims=<no value>*, *initial=<no value>*, *where=<no value>*)

Return the maximum of an array or maximum along an axis.

`amax` is an alias of `max`.

See also:

`max`

alias of this function

`ndarray.max`

equivalent method

`ma.amin` (*a*, *axis=None*, *out=None*, *keepdims=<no value>*, *initial=<no value>*, *where=<no value>*)

Return the minimum of an array or minimum along an axis.

`amin` is an alias of `min`.

See also:

min

alias of this function

ndarray.min

equivalent method

ma.apply_along_axis (*func1d*, *axis*, *arr*, **args*, ***kwargs*)

Apply a function to 1-D slices along the given axis.

Execute *func1d(a, *args, **kwargs)* where *func1d* operates on 1-D arrays and *a* is a 1-D slice of *arr* along *axis*.This is equivalent to (but faster than) the following use of *ndindex* and *s_*, which sets each of *ii*, *jj*, and *kk* to a tuple of indices:

```

Ni, Nk = a.shape[:axis], a.shape[axis+1:]
for ii in ndindex(Ni):
    for kk in ndindex(Nk):
        f = func1d(arr[ii + s_[:,] + kk])
        Nj = f.shape
        for jj in ndindex(Nj):
            out[ii + jj + kk] = f[jj]

```

Equivalently, eliminating the inner loop, this can be expressed as:

```

Ni, Nk = a.shape[:axis], a.shape[axis+1:]
for ii in ndindex(Ni):
    for kk in ndindex(Nk):
        out[ii + s_[:,] + kk] = func1d(arr[ii + s_[:,] + kk])

```

Parameters**func1d**[function (M,) -> (Nj,...)] This function should accept 1-D arrays. It is applied to 1-D slices of *arr* along the specified axis.**axis**[integer] Axis along which *arr* is sliced.**arr**

[ndarray (Ni..., M, Nk...)] Input array.

args[any] Additional arguments to *func1d*.**kwargs**[any] Additional named arguments to *func1d*.**Returns****out**[ndarray (Ni..., Nj..., Nk...)] The output array. The shape of *out* is identical to the shape of *arr*, except along the *axis* dimension. This axis is removed, and replaced with new dimensions equal to the shape of the return value of *func1d*. So if *func1d* returns a scalar *out* will have one fewer dimensions than *arr*.**See also:****apply_over_axes**

Apply a function repeatedly over multiple axes.

Examples

```
>>> import numpy as np
>>> def my_func(a):
...     """Average first and last element of a 1-D array"""
...     return (a[0] + a[-1]) * 0.5
>>> b = np.array([[1,2,3], [4,5,6], [7,8,9]])
>>> np.apply_along_axis(my_func, 0, b)
array([4., 5., 6.])
>>> np.apply_along_axis(my_func, 1, b)
array([2., 5., 8.])
```

For a function that returns a 1D array, the number of dimensions in *outarr* is the same as *arr*.

```
>>> b = np.array([[8,1,7], [4,3,9], [5,2,6]])
>>> np.apply_along_axis(sorted, 1, b)
array([[1, 7, 8],
       [3, 4, 9],
       [2, 5, 6]])
```

For a function that returns a higher dimensional array, those dimensions are inserted in place of the *axis* dimension.

```
>>> b = np.array([[1,2,3], [4,5,6], [7,8,9]])
>>> np.apply_along_axis(np.diag, -1, b)
array([[1, 0, 0],
       [0, 2, 0],
       [0, 0, 3]],
       [[4, 0, 0],
       [0, 5, 0],
       [0, 0, 6]],
       [[7, 0, 0],
       [0, 8, 0],
       [0, 0, 9]])
```

`ma.apply_over_axes` (*func*, *a*, *axes*)

Apply a function repeatedly over multiple axes.

func is called as *res = func(a, axis)*, where *axis* is the first element of *axes*. The result *res* of the function call must have either the same dimensions as *a* or one less dimension. If *res* has one less dimension than *a*, a dimension is inserted before *axis*. The call to *func* is then repeated for each axis in *axes*, with *res* as the first argument.

Parameters

func

[function] This function must take two arguments, *func(a, axis)*.

a

[array_like] Input array.

axes

[array_like] Axes over which *func* is applied; the elements must be integers.

Returns

apply_over_axis

[ndarray] The output array. The number of dimensions is the same as *a*, but the shape can be different. This depends on whether *func* changes the shape of its output with respect to its input.

See also:

`apply_along_axis`

Apply a function to 1-D slices of an array along the given axis.

Examples

```

>>> import numpy as np
>>> a = np.ma.arange(24).reshape(2,3,4)
>>> a[:,0,1] = np.ma.masked
>>> a[:,1,:] = np.ma.masked
>>> a
masked_array(
  data=[[0, --, 2, 3],
        [--, --, --, --],
        [8, 9, 10, 11]],
  mask=[[False,  True, False, False],
        [ True,  True,  True,  True],
        [False, False, False, False]],
  fill_value=999999)
>>> np.ma.apply_over_axes(np.ma.sum, a, [0,2])
masked_array(
  data=[[46],
        [--],
        [124]]],
  mask=[[False],
        [ True],
        [False]]],
  fill_value=999999)

```

Tuple axis arguments to ufuncs are equivalent:

```

>>> np.ma.sum(a, axis=(0,2)).reshape((1,-1,1))
masked_array(
  data=[[46],
        [--],
        [124]]],
  mask=[[False],
        [ True],
        [False]]],
  fill_value=999999)

```

`ma.arange([start, ]stop, [step, ]dtype=None, *, device=None, like=None)`

Return evenly spaced values within a given interval.

`arange` can be called with a varying number of positional arguments:

- `arange(stop)`: Values are generated within the half-open interval `[0, stop)` (in other words, the interval including `start` but excluding `stop`).
- `arange(start, stop)`: Values are generated within the half-open interval `[start, stop)`.
- `arange(start, stop, step)`: Values are generated within the half-open interval `[start, stop)`, with spacing between values given by `step`.

For integer arguments the function is roughly equivalent to the Python built-in `range`, but returns an `ndarray` rather than a `range` instance.

When using a non-integer step, such as 0.1, it is often better to use `numpy.linspace`.

See the Warning sections below for more information.

Parameters

start

[integer or real, optional] Start of interval. The interval includes this value. The default start value is 0.

stop

[integer or real] End of interval. The interval does not include this value, except in some cases where *step* is not an integer and floating point round-off affects the length of *out*.

step

[integer or real, optional] Spacing between values. For any output *out*, this is the distance between two adjacent values, `out[i+1] - out[i]`. The default step size is 1. If *step* is specified as a position argument, *start* must also be given.

dtype

[dtype, optional] The type of the output array. If *dtype* is not given, infer the data type from the other input arguments.

device

[str, optional] The device on which to place the created array. Default: `None`. For Array-API interoperability only, so must be `"cpu"` if passed.

New in version 2.0.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

arange

[MaskedArray] Array of evenly spaced values.

For floating point arguments, the length of the result is `ceil((stop - start)/step)`. Because of floating point overflow, this rule may result in the last element of *out* being greater than *stop*.

Warning: The length of the output might not be numerically stable.

Another stability issue is due to the internal implementation of `numpy.arange`. The actual step value used to populate the array is `dtype(start + step) - dtype(start)` and not *step*. Precision loss can occur here, due to casting or due to using floating points when *start* is much larger than *step*. This can lead to unexpected behaviour. For example:

```
>>> np.arange(0, 5, 0.5, dtype=np.int_)
array([0, 0, 0, 0, 0, 0, 0, 0, 0, 0])
>>> np.arange(-3, 3, 0.5, dtype=np.int_)
array([-3, -2, -1,  0,  1,  2,  3,  4,  5,  6,  7,  8])
```

In such cases, the use of `numpy.linspace` should be preferred.

The built-in `range` generates Python built-in integers that have arbitrary size, while `numpy.arange` produces `numpy.int32` or `numpy.int64` numbers. This may result in incorrect results for large integer values:

```
>>> power = 40
>>> modulo = 10000
>>> x1 = [(n ** power) % modulo for n in range(8)]
>>> x2 = [(n ** power) % modulo for n in np.arange(8)]
>>> print(x1)
[0, 1, 7776, 8801, 6176, 625, 6576, 4001] # correct
>>> print(x2)
[0, 1, 7776, 7185, 0, 5969, 4816, 3361] # incorrect
```

See also:

`numpy.linspace`

Evenly spaced numbers with careful handling of endpoints.

`numpy.ogrid`

Arrays of evenly spaced numbers in N-dimensions.

`numpy.mgrid`

Grid-shaped arrays of evenly spaced numbers in N-dimensions.

how-to-partition

Examples

```
>>> import numpy as np
>>> np.arange(3)
array([0, 1, 2])
>>> np.arange(3.0)
array([ 0.,  1.,  2.])
>>> np.arange(3,7)
array([3, 4, 5, 6])
>>> np.arange(3,7,2)
array([3, 5])
```

`ma.choose` (*indices, choices, out=None, mode='raise'*)

Use an index array to construct a new array from a list of choices.

Given an array of integers and a list of *n* choice arrays, this method will create a new array that merges each of the choice arrays. Where a value in *index* is *i*, the new array will have the value that *choices[i]* contains in the same place.

Parameters

indices

[ndarray of ints] This array must contain integers in $[0, n-1]$, where *n* is the number of choices.

choices

[sequence of arrays] Choice arrays. The index array and all of the choices should be broadcastable to the same shape.

out

[array, optional] If provided, the result will be inserted into this array. It should be of the appropriate shape and *dtype*.

mode

[{'raise', 'wrap', 'clip'}, optional] Specifies how out-of-bounds indices will behave.

- 'raise' : raise an error
- 'wrap' : wrap around
- 'clip' : clip to the range

Returns**merged_array**

[array]

See also:

choose

equivalent function

Examples

```
>>> import numpy as np
>>> choice = np.array([[1,1,1], [2,2,2], [3,3,3]])
>>> a = np.array([2, 1, 0])
>>> np.ma.choose(a, choice)
masked_array(data=[3, 2, 1],
              mask=False,
              fill_value=999999)
```

`ma.compress_nd(x, axis=None)`

Suppress slices from multiple dimensions which contain masked values.

Parameters**x**

[array_like, MaskedArray] The array to operate on. If not a MaskedArray instance (or if no array elements are masked), *x* is interpreted as a MaskedArray with *mask* set to *nomask*.

axis

[tuple of ints or int, optional] Which dimensions to suppress slices from can be configured with this parameter. - If axis is a tuple of ints, those are the axes to suppress slices from. - If axis is an int, then that is the only axis to suppress slices from. - If axis is None, all axis are selected.

Returns**compress_array**

[ndarray] The compressed array.

Examples

```
>>> import numpy as np
>>> arr = [[1, 2], [3, 4]]
>>> mask = [[0, 1], [0, 0]]
>>> x = np.ma.array(arr, mask=mask)
>>> np.ma.compress_nd(x, axis=0)
array([[3, 4]])
>>> np.ma.compress_nd(x, axis=1)
array([[1],
       [3]])
>>> np.ma.compress_nd(x)
array([[3]])
```

`ma.convolve(a, v, mode='full', propagate_mask=True)`

Returns the discrete, linear convolution of two one-dimensional sequences.

Parameters

a, v

[array_like] Input sequences.

mode

[{'valid', 'same', 'full'}, optional] Refer to the *np.convolve* docstring.

propagate_mask

[bool] If True, then if any masked element is included in the sum for a result element, then the result is masked. If False, then the result element is only masked if no non-masked cells contribute towards it

Returns

out

[MaskedArray] Discrete, linear convolution of *a* and *v*.

See also:

numpy.convolve

Equivalent function in the top-level NumPy module.

`ma.correlate(a, v, mode='valid', propagate_mask=True)`

Cross-correlation of two 1-dimensional sequences.

Parameters

a, v

[array_like] Input sequences.

mode

[{'valid', 'same', 'full'}, optional] Refer to the *np.convolve* docstring. Note that the default is 'valid', unlike *convolve*, which uses 'full'.

propagate_mask

[bool] If True, then a result element is masked if any masked element contributes towards it. If False, then a result element is only masked if no non-masked element contribute towards it

Returns

out

[MaskedArray] Discrete cross-correlation of *a* and *v*.

See also:

[`numpy.correlate`](#)

Equivalent function in the top-level NumPy module.

Examples

Basic correlation:

```
>>> a = np.ma.array([1, 2, 3])
>>> v = np.ma.array([0, 1, 0])
>>> np.ma.correlate(a, v, mode='valid')
masked_array(data=[2],
              mask=[False],
              fill_value=999999)
```

Correlation with masked elements:

```
>>> a = np.ma.array([1, 2, 3], mask=[False, True, False])
>>> v = np.ma.array([0, 1, 0])
>>> np.ma.correlate(a, v, mode='valid', propagate_mask=True)
masked_array(data=[--],
              mask=[ True],
              fill_value=999999,
              dtype=int64)
```

Correlation with different modes and mixed array types:

```
>>> a = np.ma.array([1, 2, 3])
>>> v = np.ma.array([0, 1, 0])
>>> np.ma.correlate(a, v, mode='full')
masked_array(data=[0, 1, 2, 3, 0],
              mask=[False, False, False, False, False],
              fill_value=999999)
```

`ma.ediff1d(arr, to_end=None, to_begin=None)`

Compute the differences between consecutive elements of an array.

This function is the equivalent of [`numpy.ediff1d`](#) that takes masked values into account, see [`numpy.ediff1d`](#) for details.

See also:

[`numpy.ediff1d`](#)

Equivalent function for ndarrays.

Examples

```
>>> import numpy as np
>>> arr = np.ma.array([1, 2, 4, 7, 0])
>>> np.ma.ediff1d(arr)
masked_array(data=[ 1,  2,  3, -7],
              mask=False,
              fill_value=999999)
```

`ma.flatten_mask(mask)`

Returns a completely flattened version of the mask, where nested fields are collapsed.

Parameters

mask

[array_like] Input array, which will be interpreted as booleans.

Returns

flattened_mask

[ndarray of bools] The flattened input.

Examples

```
>>> import numpy as np
>>> mask = np.array([0, 0, 1])
>>> np.ma.flatten_mask(mask)
array([False, False,  True])
```

```
>>> mask = np.array([(0, 0), (0, 1)], dtype=[('a', bool), ('b', bool)])
>>> np.ma.flatten_mask(mask)
array([False, False, False,  True])
```

```
>>> mdtype = [('a', bool), ('b', [('ba', bool), ('bb', bool)])]
>>> mask = np.array([(0, (0, 0)), (0, (0, 1))], dtype=mdtype)
>>> np.ma.flatten_mask(mask)
array([False, False, False, False, False,  True])
```

`ma.flatten_structured_array(a)`

Flatten a structured array.

The data type of the output is chosen such that it can represent all of the (nested) fields.

Parameters

a

[structured array]

Returns

output

[masked array or ndarray] A flattened masked array if the input is a masked array, otherwise a standard ndarray.

Examples

```
>>> import numpy as np
>>> ndtype = [('a', int), ('b', float)]
>>> a = np.array([(1, 1), (2, 2)], dtype=ndtype)
>>> np.ma.flatten_structured_array(a)
array([[1., 1.],
       [2., 2.]])
```

`ma.fromflex` (*fxarray*)

Build a masked array from a suitable flexible-type array.

The input array has to have a data-type with `_data` and `_mask` fields. This type of array is output by `MaskedArray.toflex`.

Parameters

`fxarray`

[ndarray] The structured input array, containing `_data` and `_mask` fields. If present, other fields are discarded.

Returns

`result`

[MaskedArray] The constructed masked array.

See also:

`MaskedArray.toflex`

Build a flexible-type array from a masked array.

Examples

```
>>> import numpy as np
>>> x = np.ma.array(np.arange(9).reshape(3, 3), mask=[0] + [1, 0] * 4)
>>> rec = x.toflex()
>>> rec
array([(0, False), (1, True), (2, False)],
      [(3, True), (4, False), (5, True)],
      [(6, False), (7, True), (8, False)]],
      dtype=[('_data', '<i8'), ('_mask', '?')])
>>> x2 = np.ma.fromflex(rec)
>>> x2
masked_array(
  data=[[0, --, 2],
        [--, 4, --],
        [6, --, 8]],
  mask=[[False, True, False],
        [ True, False, True],
        [False, True, False]],
  fill_value=999999)
```

Extra fields can be present in the structured array but are discarded:

```
>>> dt = [('_data', '<i4'), ('_mask', '|b1'), ('field3', '<f4')]
>>> rec2 = np.zeros((2, 2), dtype=dt)
>>> rec2
```

(continues on next page)

(continued from previous page)

```

array([[ (0, False, 0.), (0, False, 0.)],
       [(0, False, 0.), (0, False, 0.)]],
      dtype=[('_data', '<i4'), ('_mask', '?'), ('field3', '<f4')])
>>> y = np.ma.fromflex(rec2)
>>> y
masked_array(
  data=[[0, 0],
        [0, 0]],
  mask=[[False, False],
        [False, False]],
  fill_value=np.int64(999999),
  dtype=int32)

```

ma.indices (*dimensions*, *dtype*=<class 'int'>, *sparse*=False, *, *fill_value*=None, *hardmask*=False)

Return an array representing the indices of a grid.

Compute an array where the subarrays contain index values 0, 1, ... varying only along the corresponding axis.

Parameters

dimensions

[sequence of ints] The shape of the grid.

dtype

[dtype, optional] Data type of the result.

sparse

[boolean, optional] Return a sparse representation of the grid instead of a dense representation. Default is False.

Returns

grid

[one MaskedArray or tuple of MaskedArrays]

If sparse is False:

Returns one array of grid indices, `grid.shape = (len(dimensions),) + tuple(dimensions)`.

If sparse is True:

Returns a tuple of arrays, with `grid[i].shape = (1, ..., 1, dimensions[i], 1, ..., 1)` with `dimensions[i]` in the *i*th place

See also:

[*mgrid*](#), [*ogrid*](#), [*meshgrid*](#)

Notes

The output shape in the dense case is obtained by prepending the number of dimensions in front of the tuple of dimensions, i.e. if *dimensions* is a tuple (*r0*, ..., *rN-1*) of length *N*, the output shape is (*N*, *r0*, ..., *rN-1*).

The subarrays `grid[k]` contains the N-D array of indices along the *k*-th axis. Explicitly:

```
grid[k, i0, i1, ..., iN-1] = ik
```

Examples

```
>>> import numpy as np
>>> grid = np.indices((2, 3))
>>> grid.shape
(2, 2, 3)
>>> grid[0]          # row indices
array([[0, 0, 0],
       [1, 1, 1]])
>>> grid[1]          # column indices
array([[0, 1, 2],
       [0, 1, 2]])
```

The indices can be used as an index into an array.

```
>>> x = np.arange(20).reshape(5, 4)
>>> row, col = np.indices((2, 3))
>>> x[row, col]
array([[0, 1, 2],
       [4, 5, 6]])
```

Note that it would be more straightforward in the above example to extract the required elements directly with `x[:2, :3]`.

If `sparse` is set to `true`, the grid will be returned in a sparse representation.

```
>>> i, j = np.indices((2, 3), sparse=True)
>>> i.shape
(2, 1)
>>> j.shape
(1, 3)
>>> i          # row indices
array([[0],
       [1]])
>>> j          # column indices
array([[0, 1, 2]])
```

`ma.left_shift(a, n)`

Shift the bits of an integer to the left.

This is the masked array version of `numpy.left_shift`, for details see that function.

See also:

`numpy.left_shift`

Examples

Shift with a masked array:

```
>>> arr = np.ma.array([10, 20, 30], mask=[False, True, False])
>>> np.ma.left_shift(arr, 1)
masked_array(data=[20, --, 60],
             mask=[False,  True, False],
             fill_value=999999)
```

Large shift:

```
>>> np.ma.left_shift(10, 10)
masked_array(data=10240,
             mask=False,
             fill_value=999999)
```

Shift with a scalar and an array:

```
>>> scalar = 10
>>> arr = np.ma.array([1, 2, 3], mask=[False, True, False])
>>> np.ma.left_shift(scalar, arr)
masked_array(data=[20, --, 80],
             mask=[False, True, False],
             fill_value=999999)
```

`ma.ndim(obj)`

Return the number of dimensions of an array.

Parameters

a

[array_like] Input array. If it is not already an ndarray, a conversion is attempted.

Returns

number_of_dimensions

[int] The number of dimensions in *a*. Scalars are zero-dimensional.

See also:

[`ndarray.ndim`](#)

equivalent method

[`shape`](#)

dimensions of array

[`ndarray.shape`](#)

dimensions of array

Examples

```
>>> import numpy as np
>>> np.ndim([[1, 2, 3], [4, 5, 6]])
2
>>> np.ndim(np.array([[1, 2, 3], [4, 5, 6]]))
2
>>> np.ndim(1)
0
```

`ma.put(a, indices, values, mode='raise')`

Set storage-indexed locations to corresponding values.

This function is equivalent to [`MaskedArray.put`](#), see that method for details.

See also:

[`MaskedArray.put`](#)

Examples

Putting values in a masked array:

```
>>> a = np.ma.array([1, 2, 3, 4], mask=[False, True, False, False])
>>> np.ma.put(a, [1, 3], [10, 30])
>>> a
masked_array(data=[ 1, 10,  3, 30],
             mask=False,
             fill_value=999999)
```

Using put with a 2D array:

```
>>> b = np.ma.array([[1, 2], [3, 4]], mask=[[False, True], [False, False]])
>>> np.ma.put(b, [[0, 1], [1, 0]], [[10, 20], [30, 40]])
>>> b
masked_array(
  data=[[40, 30],
        [ 3,  4]],
  mask=False,
  fill_value=999999)
```

`ma.putmask(a, mask, values)`

Changes elements of an array based on conditional and input values.

This is the masked array version of [`numpy.putmask`](#), for details see [`numpy.putmask`](#).

See also:

[`numpy.putmask`](#)

Notes

Using a masked array as *values* will **not** transform a [`ndarray`](#) into a [`MaskedArray`](#).

Examples

```
>>> import numpy as np
>>> arr = [[1, 2], [3, 4]]
>>> mask = [[1, 0], [0, 0]]
>>> x = np.ma.array(arr, mask=mask)
>>> np.ma.putmask(x, x < 4, 10*x)
>>> x
masked_array(
  data=[[-, 20],
        [30, 4]],
  mask=[[ True, False],
        [False, False]],
  fill_value=999999)
>>> x.data
array([[10, 20],
       [30,  4]])
```

`ma.right_shift(a, n)`

Shift the bits of an integer to the right.

This is the masked array version of `numpy.right_shift`, for details see that function.

See also:

`numpy.right_shift`

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = [11, 3, 8, 1]
>>> mask = [0, 0, 0, 1]
>>> masked_x = ma.masked_array(x, mask)
>>> masked_x
masked_array(data=[11, 3, 8, --],
             mask=[False, False, False,  True],
             fill_value=999999)
>>> ma.right_shift(masked_x, 1)
masked_array(data=[5, 1, 4, --],
             mask=[False, False, False,  True],
             fill_value=999999)
```

`ma.round_(a, decimals=0, out=None)`

Return a copy of a, rounded to 'decimals' places.

Deprecated since version 2.5: `numpy.ma.round_` is deprecated. Use `numpy.ma.round` instead.

When 'decimals' is negative, it specifies the number of positions to the left of the decimal point. The real and imaginary parts of complex numbers are rounded separately. Nothing is done if the array is not of float type and 'decimals' is greater than or equal to 0.

Parameters

decimals

[int] Number of decimals to round to. May be negative.

out

[array_like] Existing array to use for output. If not given, returns a default copy of a.

Notes

If out is given and does not have a mask attribute, the mask of a is lost!

Examples

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = [11.2, -3.973, 0.801, -1.41]
>>> mask = [0, 0, 0, 1]
>>> masked_x = ma.masked_array(x, mask)
>>> masked_x
masked_array(data=[11.2, -3.973, 0.801, --],
             mask=[False, False, False, True],
             fill_value=1e+20)
>>> ma.round_(masked_x)
masked_array(data=[11.0, -4.0, 1.0, --],
             mask=[False, False, False, True],
             fill_value=1e+20)
>>> ma.round(masked_x, decimals=1)
masked_array(data=[11.2, -4.0, 0.8, --],
             mask=[False, False, False, True],
             fill_value=1e+20)
>>> ma.round_(masked_x, decimals=-1)
masked_array(data=[10.0, -0.0, 0.0, --],
             mask=[False, False, False, True],
             fill_value=1e+20)
```

`ma.take` (*a*, *indices*, *axis=None*, *out=None*, *mode='raise'*)

`ma.where` (*condition*, *x=<no value>*, *y=<no value>*)

Return a masked array with elements from *x* or *y*, depending on condition.

Note: When only *condition* is provided, this function is identical to `nonzero`. The rest of this documentation covers only the case where all three arguments are provided.

Parameters

condition

[array_like, bool] Where True, yield *x*, otherwise yield *y*.

x, y

[array_like, optional] Values from which to choose. *x*, *y* and *condition* need to be broadcastable to some shape.

Returns

out

[MaskedArray] A masked array with *masked* elements where the condition is masked, elements from *x* where *condition* is True, and elements from *y* elsewhere.

See also:

`numpy.where`

Equivalent function in the top-level NumPy module.

`nonzero`

The function that is called when *x* and *y* are omitted

Examples

```
>>> import numpy as np
>>> x = np.ma.array(np.arange(9.).reshape(3, 3), mask=[[0, 1, 0],
...                                                    [1, 0, 1],
...                                                    [0, 1, 0]])
>>> x
masked_array(
  data=[[0.0, --, 2.0],
        [--, 4.0, --],
        [6.0, --, 8.0]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=1e+20)
>>> np.ma.where(x > 5, x, -3.1416)
masked_array(
  data=[[-3.1416, --, -3.1416],
        [--, -3.1416, --],
        [6.0, --, 8.0]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=1e+20)
```

Matrix library (`numpy.matlib`)

This module contains all functions in the *numpy* namespace, with the following replacement functions that return *matrices* instead of *ndarrays*.

Functions that are also in the *numpy* namespace and return matrices

<code>matrix(data[, dtype, copy])</code>	Returns a matrix from an array-like object, or from a string of data.
<code>asmatrix(data[, dtype])</code>	Interpret the input as a matrix.
<code>bmat(obj[, ldict, gdict])</code>	Build a matrix object from a string, nested sequence, or array.

Replacement functions in *matlib*

<code>empty(shape[, dtype, order])</code>	Return a new matrix of given shape and type, without initializing entries.
<code>zeros(shape[, dtype, order])</code>	Return a matrix of given shape and type, filled with zeros.
<code>ones(shape[, dtype, order])</code>	Matrix of ones.
<code>eye(n[, M, k, dtype, order])</code>	Return a matrix with ones on the diagonal and zeros elsewhere.
<code>identity(n[, dtype])</code>	Returns the square identity matrix of given size.
<code>repmat(a, m, n)</code>	Repeat a 0-D to 2-D array or matrix MxN times.
<code>rand(*args)</code>	Return a matrix of random values with given shape.
<code>randn(*args)</code>	Return a random matrix with data from the "standard normal" distribution.

`matlib.empty(shape, dtype=None, order='C')`

Return a new matrix of given shape and type, without initializing entries.

Parameters

shape

[int or tuple of int] Shape of the empty matrix.

dtype

[data-type, optional] Desired output data-type.

order

[{'C', 'F'}, optional] Whether to store multi-dimensional data in row-major (C-style) or column-major (Fortran-style) order in memory.

See also:

[`numpy.empty`](#)

Equivalent array function.

[`matlib.zeros`](#)

Return a matrix of zeros.

[`matlib.ones`](#)

Return a matrix of ones.

Notes

Unlike other matrix creation functions (e.g. [`matlib.zeros`](#), [`matlib.ones`](#)), [`matlib.empty`](#) does not initialize the values of the matrix, and may therefore be marginally faster. However, the values stored in the newly allocated matrix are arbitrary. For reproducible behavior, be sure to set each element of the matrix before reading.

Examples

```
>>> import numpy.matlib
>>> np.matlib.empty((2, 2))      # filled with random data
matrix([[ 6.76425276e-320,  9.79033856e-307], # random
        [ 7.39337286e-309,  3.22135945e-309]])
>>> np.matlib.empty((2, 2), dtype=np.int_)
matrix([[ 6600475,      0], # random
        [ 6586976, 22740995]])
```

`matlib.zeros(shape, dtype=None, order='C')`

Return a matrix of given shape and type, filled with zeros.

Parameters

shape

[int or sequence of ints] Shape of the matrix

dtype

[data-type, optional] The desired data-type for the matrix, default is float.

order

[{'C', 'F'}, optional] Whether to store the result in C- or Fortran-contiguous order, default is 'C'.

Returns

out

[matrix] Zero matrix of given shape, dtype, and order.

See also:**`numpy.zeros`**

Equivalent array function.

`matlib.ones`

Return a matrix of ones.

Notes

If `shape` has length one i.e. $(N,)$, or is a scalar N , `out` becomes a single row matrix of shape $(1, N)$.

Examples

```
>>> import numpy.matlib
>>> np.matlib.zeros((2, 3))
matrix([[0., 0., 0.],
        [0., 0., 0.]])
```

```
>>> np.matlib.zeros(2)
matrix([[0., 0.]])
```

`matlib.ones` (*shape*, *dtype=None*, *order='C'*)

Matrix of ones.

Return a matrix of given shape and type, filled with ones.

Parameters

shape

[[sequence of ints, int]] Shape of the matrix

dtype[data-type, optional] The desired data-type for the matrix, default is `np.float64`.**order**

[['C', 'F'], optional] Whether to store matrix in C- or Fortran-contiguous order, default is 'C'.

Returns

out

[matrix] Matrix of ones of given shape, dtype, and order.

See also:**`ones`**

Array of ones.

`matlib.zeros`

Zero matrix.

Notes

If `shape` has length one i.e. $(N,)$, or is a scalar N , `out` becomes a single row matrix of shape $(1, N)$.

Examples

```
>>> np.matlib.ones((2,3))
matrix([[1.,  1.,  1.],
        [1.,  1.,  1.]])
```

```
>>> np.matlib.ones(2)
matrix([[1.,  1.]])
```

`matlib.eye` (*n*, *M=None*, *k=0*, *dtype=<class 'float'>*, *order='C'*)

Return a matrix with ones on the diagonal and zeros elsewhere.

Parameters

n

[int] Number of rows in the output.

M

[int, optional] Number of columns in the output, defaults to *n*.

k

[int, optional] Index of the diagonal: 0 refers to the main diagonal, a positive value refers to an upper diagonal, and a negative value to a lower diagonal.

dtype

[dtype, optional] Data-type of the returned matrix.

order

[{'C', 'F'}, optional] Whether the output should be stored in row-major (C-style) or column-major (Fortran-style) order in memory.

Returns

I

[matrix] A $n \times M$ matrix where all elements are equal to zero, except for the *k*-th diagonal, whose values are equal to one.

See also:

[`numpy.eye`](#)

Equivalent array function.

[`identity`](#)

Square identity matrix.

Examples

```
>>> import numpy.matlib
>>> np.matlib.eye(3, k=1, dtype=np.float64)
matrix([[0.,  1.,  0.],
        [0.,  0.,  1.],
        [0.,  0.,  0.]])
```

`matlib.identity` (*n*, *dtype=None*)

Returns the square identity matrix of given size.

Parameters

n

[int] Size of the returned identity matrix.

dtype

[data-type, optional] Data-type of the output. Defaults to `float`.

Returns

out

[matrix] $n \times n$ matrix with its main diagonal set to one, and all other elements zero.

See also:

`numpy.identity`

Equivalent array function.

`matlib.eye`

More general matrix identity function.

Examples

```
>>> import numpy.matlib
>>> np.matlib.identity(3, dtype=np.int_)
matrix([[1, 0, 0],
        [0, 1, 0],
        [0, 0, 1]])
```

`matlib.repmat` (*a*, *m*, *n*)

Repeat a 0-D to 2-D array or matrix $M \times N$ times.

Parameters

a

[array_like] The array or matrix to be repeated.

m, n

[int] The number of times *a* is repeated along the first and second axes.

Returns

out

[ndarray] The result of repeating *a*.

Examples

```
>>> import numpy.matlib
>>> a0 = np.array(1)
>>> np.matlib.repmat(a0, 2, 3)
array([[1, 1, 1],
       [1, 1, 1]])
```

```
>>> a1 = np.arange(4)
>>> np.matlib.repmat(a1, 2, 2)
array([[0, 1, 2, 3, 0, 1, 2, 3],
       [0, 1, 2, 3, 0, 1, 2, 3]])
```

```
>>> a2 = np.asmatrix(np.arange(6).reshape(2, 3))
>>> np.matlib.repmat(a2, 2, 3)
matrix([[0, 1, 2, 0, 1, 2, 0, 1, 2],
        [3, 4, 5, 3, 4, 5, 3, 4, 5],
        [0, 1, 2, 0, 1, 2, 0, 1, 2],
        [3, 4, 5, 3, 4, 5, 3, 4, 5]])
```

`matlib.rand(*args)`

Return a matrix of random values with given shape.

Create a matrix of the given shape and propagate it with random samples from a uniform distribution over `[0, 1)`.

Parameters

`*args`

[Arguments] Shape of the output. If given as N integers, each integer specifies the size of one dimension. If given as a tuple, this tuple gives the complete shape.

Returns

`out`

[ndarray] The matrix of random values with shape given by `*args`.

See also:

[`randn`](#), [`numpy.random.RandomState.rand`](#)

Examples

```
>>> np.random.seed(123)
>>> import numpy.matlib
>>> np.matlib.rand(2, 3)
matrix([[0.69646919, 0.28613933, 0.22685145],
        [0.55131477, 0.71946897, 0.42310646]])
>>> np.matlib.rand((2, 3))
matrix([[0.9807642 , 0.68482974, 0.4809319 ],
        [0.39211752, 0.34317802, 0.72904971]])
```

If the first argument is a tuple, other arguments are ignored:

```
>>> np.matlib.rand((2, 3), 4)
matrix([[0.43857224, 0.0596779 , 0.39804426],
        [0.73799541, 0.18249173, 0.17545176]])
```

`matlib.randn(*args)`

Return a random matrix with data from the “standard normal” distribution.

`randn` generates a matrix filled with random floats sampled from a univariate “normal” (Gaussian) distribution of mean 0 and variance 1.

Parameters

***args**

[Arguments] Shape of the output. If given as N integers, each integer specifies the size of one dimension. If given as a tuple, this tuple gives the complete shape.

Returns

Z

[matrix of floats] A matrix of floating-point samples drawn from the standard normal distribution.

See also:

`rand`, `numpy.random.RandomState.randn`

Notes

For random samples from the normal distribution with mean `mu` and standard deviation `sigma`, use:

```
sigma * np.matlib.randn(...) + mu
```

Examples

```
>>> np.random.seed(123)
>>> import numpy.matlib
>>> np.matlib.randn(1)
matrix([[ -1.0856306]])
>>> np.matlib.randn(1, 2, 3)
matrix([[ 0.99734545,  0.2829785 , -1.50629471],
        [-0.57860025,  1.65143654, -2.42667924]])
```

Two-by-four matrix of samples from the normal distribution with mean 3 and standard deviation 2.5:

```
>>> 2.5 * np.matlib.randn((2, 4)) + 3
matrix([[ 1.92771843,  6.16484065,  0.83314899,  1.30278462],
        [ 2.76322758,  6.72847407,  1.40274501,  1.8900451 ]])
```

1.2 Array objects

NumPy provides an N-dimensional array type, the *ndarray*, which describes a collection of “items” of the same type. The items can be *indexed* using for example N integers.

All ndarrays are homogeneous: every item takes up the same size block of memory, and all blocks are interpreted in exactly the same way. How each item in the array is to be interpreted is specified by a separate *data-type object*, one of which is associated with every array. In addition to basic types (integers, floats, *etc.*), the data type objects can also represent data structures.

An item extracted from an array, *e.g.*, by indexing, is represented by a Python object whose type is one of the *array scalar types* built in NumPy. The array scalars allow easy manipulation of also more complicated arrangements of data.

Fig. 1: **Figure** Conceptual diagram showing the relationship between the three fundamental objects used to describe the data in an array: 1) the ndarray itself, 2) the data-type object that describes the layout of a single fixed-size element of the array, 3) the array-scalar Python object that is returned when a single element of the array is accessed.

1.2.1 The N-dimensional array (ndarray)

An *ndarray* is a (usually fixed-size) multidimensional container of items of the same type and size. The number of dimensions and items in an array is defined by its *shape*, which is a *tuple* of N non-negative integers that specify the sizes of each dimension. The type of items in the array is specified by a separate *data-type object (dtype)*, one of which is associated with each ndarray.

As with other container objects in Python, the contents of an *ndarray* can be accessed and modified by *indexing or slicing* the array (using, for example, N integers), and via the methods and attributes of the *ndarray*.

Different *ndarrays* can share the same data, so that changes made in one *ndarray* may be visible in another. That is, an ndarray can be a “view” to another ndarray, and the data it is referring to is taken care of by the “base” ndarray. ndarrays can also be views to memory owned by Python *strings* or objects implementing the *memoryview* or *array* interfaces.

Example

A 2-dimensional array of size 2 x 3, composed of 4-byte integer elements:

```
>>> import numpy as np

>>> x = np.array([[1, 2, 3], [4, 5, 6]], np.int32)
>>> type(x)
<class 'numpy.ndarray'>
>>> x.shape
(2, 3)
>>> x.dtype
dtype('int32')
```

The array can be indexed using Python container-like syntax:

```
>>> # The element of x in the *second* row, *third* column, namely, 6.
>>> x[1, 2]
6
```

For example *slicing* can produce views of the array:

```
>>> y = x[:,1]
>>> y
array([2, 5], dtype=int32)
>>> y[0] = 9 # this also changes the corresponding element in x
>>> y
array([9, 5], dtype=int32)
>>> x
array([[1, 9, 3],
       [4, 5, 6]], dtype=int32)
```

Constructing arrays

New arrays can be constructed using the routines detailed in *Array creation routines*, and also by using the low-level *ndarray* constructor:

```
ndarray(shape[, dtype, buffer, offset, ...])
```

An array object represents a multidimensional, homogeneous array of fixed-size items.

class `numpy.ndarray` (*shape, dtype=np.float64, buffer=None, offset=0, strides=None, order=None*)

An array object represents a multidimensional, homogeneous array of fixed-size items. An associated data-type object describes the format of each element in the array (its byte-order, how many bytes it occupies in memory, whether it is an integer, a floating point number, or something else, etc.)

Arrays should be constructed using *array*, *zeros* or *empty* (refer to the See Also section below). The parameters given here refer to a low-level method (*ndarray(...)*) for instantiating an array.

For more information, refer to the *numpy* module and examine the methods and attributes of an array.

Parameters

(for the `__new__` method; see Notes below)

shape

[tuple of ints] Shape of created array.

dtype

[data-type, optional] Any object that can be interpreted as a numpy data type. Default is *numpy.float64*.

buffer

[object exposing buffer interface, optional] Used to fill the array with data.

offset

[int, optional] Offset of array data in buffer.

strides

[tuple of ints, optional] Strides of data in memory.

order

[{'C', 'F'}, optional] Row-major (C-style) or column-major (Fortran-style) order.

Attributes

T

[ndarray] View of the transposed array.

data

[buffer] Python buffer object pointing to the start of the array's data.

dtype

[dtype object] Data-type of the array's elements.

flags

[dict] Information about the memory layout of the array.

flat

[numpy.flatiter object] A 1-D iterator over the array.

imag

[ndarray] The imaginary part of the array.

real

[ndarray] The real part of the array.

size

[int] Number of elements in the array.

itemsize

[int] Length of one array element in bytes.

nbytes

[int] Total bytes consumed by the elements of the array.

ndim

[int] Number of array dimensions.

shape

[tuple of ints] Tuple of array dimensions.

strides

[tuple of ints] Tuple of bytes to step in each dimension when traversing an array.

ctypes

[ctypes object] An object to simplify the interaction of the array with the ctypes module.

base

[ndarray] Base object if memory is from some other object.

Methods

<i>all</i> ([axis, out, keepdims, where])	Returns True if all elements evaluate to True.
<i>any</i> ([axis, out, keepdims, where])	Returns True if any of the elements of <i>a</i> evaluate to True.
<i>argmax</i> ([axis, out, keepdims])	Return indices of the maximum values along the given axis.
<i>argmin</i> ([axis, out, keepdims])	Return indices of the minimum values along the given axis.
<i>argpartition</i> (kth[, axis, kind, order])	Returns the indices that would partition this array.
<i>argsort</i> ([axis, kind, order, stable, descending])	Returns the indices that would sort this array.
<i>astype</i> (dtype[, order, casting, subok, copy])	Copy of the array, cast to a specified type.

continues on next page

Table 6 – continued from previous page

<i>byteswap</i> ([inplace])	Swap the bytes of the array elements
<i>choose</i> (choices[, out, mode])	Use an index array to construct a new array from a set of choices.
<i>clip</i> ([min, max, out])	Return an array whose values are limited to [min, max].
<i>compress</i> (condition[, axis, out])	Return selected slices of this array along given axis.
<i>conj</i> ()	Complex-conjugate all elements.
<i>conjugate</i> ()	Return the complex conjugate, element-wise.
<i>copy</i> ([order])	Return a copy of the array.
<i>cumprod</i> ([axis, dtype, out])	Return the cumulative product of the elements along the given axis.
<i>cumsum</i> ([axis, dtype, out])	Return the cumulative sum of the elements along the given axis.
<i>diagonal</i> ([offset, axis1, axis2])	Return specified diagonals.
<i>dot</i> (other, /[, out])	Refer to <i>numpy.dot</i> for full documentation.
<i>dump</i> (file)	Dump a pickle of the array to the specified file.
<i>dumps</i> ()	Returns the pickle of the array as a string.
<i>fill</i> (value)	Fill the array with a scalar value.
<i>flatten</i> ([order])	Return a copy of the array collapsed into one dimension.
<i>getfield</i> (dtype[, offset])	Returns a field of the given array as a certain type.
<i>item</i> (*args)	Copy an element of an array to a standard Python scalar and return it.
<i>max</i> ([axis, out, keepdims, initial, where])	Return the maximum along a given axis.
<i>mean</i> ([axis, dtype, out, keepdims, where])	Returns the average of the array elements along given axis.
<i>min</i> ([axis, out, keepdims, initial, where])	Return the minimum along a given axis.
<i>nonzero</i> ()	Return the indices of the elements that are non-zero.
<i>partition</i> (kth[, axis, kind, order])	Partially sorts the elements in the array in such a way that the value of the element in k-th position is in the position it would be in a sorted array.
<i>prod</i> ([axis, dtype, out, keepdims, initial, ...])	Return the product of the array elements over the given axis
<i>put</i> (indices, values[, mode])	Set <i>a.flat</i> [<i>n</i>] = <i>values</i> [<i>n</i>] for all <i>n</i> in indices.
<i>ravel</i> ([order])	Return a flattened array.
<i>repeat</i> (repeats[, axis])	Repeat elements of an array.
<i>reshape</i> (<i>a.reshape</i>)	Returns an array containing the same data with a new shape.
<i>resize</i> (<i>a.resize</i>)	Change shape and size of array in-place.
<i>round</i> ([decimals, out])	Return <i>a</i> with each element rounded to the given number of decimals.
<i>searchsorted</i> (<i>v</i> [, side, sorter])	Find indices where elements of <i>v</i> should be inserted in <i>a</i> to maintain order.
<i>setfield</i> (<i>val</i> , dtype[, offset])	Put a value into a specified place in a field defined by a data-type.
<i>setflags</i> ([write, align, uic])	Set array flags WRITEABLE, ALIGNED, WRITEBACKIFCOPY, respectively.
<i>sort</i> ([axis, kind, order, stable, descending])	Sort an array in-place.
<i>squeeze</i> ([axis])	Remove axes of length one from <i>a</i> .
<i>std</i> ([axis, dtype, out, ddof, keepdims, ...])	Returns the standard deviation of the array elements along given axis.

continues on next page

Table 6 – continued from previous page

<code>sum([axis, dtype, out, keepdims, initial, where])</code>	Return the sum of the array elements over the given axis.
<code>swapaxes(axis1, axis2, /)</code>	Return a view of the array with <i>axis1</i> and <i>axis2</i> interchanged.
<code>take(indices[, axis, out, mode])</code>	Return an array formed from the elements of <i>a</i> at the given indices.
<code>to_device(device, /, *[, stream])</code>	For Array API compatibility.
<code>tobytes([order])</code>	Construct Python bytes containing the raw data bytes in the array.
<code>tofile(fid, /[, sep, format])</code>	Write array to a file as text or binary (default).
<code>tolist()</code>	Return the array as an <code>a.ndim</code> -levels deep nested list of Python scalars.
<code>trace([offset, axis1, axis2, dtype, out])</code>	Return the sum along diagonals of the array.
<code>transpose(*axes)</code>	Returns a view of the array with axes transposed.
<code>var([axis, dtype, out, ddof, keepdims, ...])</code>	Returns the variance of the array elements, along given axis.
<code>view([dtype][, type])</code>	New view of array with the same data.

method

`ndarray.all (axis=None, out=None, *, keepdims=<no value>, where=<no value>)`

Returns True if all elements evaluate to True.

Refer to [numpy.all](#) for full documentation.

See also:

[numpy.all](#)

equivalent function

method

`ndarray.any (axis=None, out=None, *, keepdims=<no value>, where=<no value>)`

Returns True if any of the elements of *a* evaluate to True.

Refer to [numpy.any](#) for full documentation.

See also:

[numpy.any](#)

equivalent function

method

`ndarray.argmax (axis=None, out=None, *, keepdims=False)`

Return indices of the maximum values along the given axis.

Refer to [numpy.argmax](#) for full documentation.

See also:

[numpy.argmax](#)

equivalent function

method

`ndarray.argmax` (*axis=None, out=None, *, keepdims=False*)

Return indices of the minimum values along the given axis.

Refer to [`numpy.argmax`](#) for detailed documentation.

See also:

[`numpy.argmax`](#)
equivalent function

method

`ndarray.argpartition` (*kth, axis=-1, kind='introselect', order=None*)

Returns the indices that would partition this array.

Refer to [`numpy.argpartition`](#) for full documentation.

See also:

[`numpy.argpartition`](#)
equivalent function

method

`ndarray.argsort` (*axis=-1, kind=None, order=None, *, stable=None, descending=None*)

Returns the indices that would sort this array.

Refer to [`numpy.argsort`](#) for full documentation.

See also:

[`numpy.argsort`](#)
equivalent function

method

`ndarray.astype` (*dtype, order='K', casting='unsafe', subok=True, copy=True*)

Copy of the array, cast to a specified type.

Parameters

dtype

[str or dtype] Typecode or data-type to which the array is cast.

order

[['C', 'F', 'A', 'K'], optional] Controls the memory layout order of the result. 'C' means C order, 'F' means Fortran order, 'A' means 'F' order if all the arrays are Fortran contiguous, 'C' order otherwise, and 'K' means as close to the order the array elements appear in memory as possible. Default is 'K'.

casting

[['no', 'equiv', 'safe', 'same_kind', 'same_value', 'unsafe'], optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility.

- 'no' means the data types should not be cast at all.
- 'equiv' means only byte-order changes are allowed.
- 'safe' means only casts which can preserve values are allowed.
- 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed.

- 'unsafe' means any data conversions may be done.
- 'same_value' means any data conversions may be done, but the values must not change, including rounding of floats or overflow of ints

New in version 2.4: Support for 'same_value' was added.

subok

[bool, optional] If True, then sub-classes will be passed-through (default), otherwise the returned array will be forced to be a base-class array.

copy

[bool, optional] By default, `astype` always returns a newly allocated array. If this is set to false, and the *dtype*, *order*, and *subok* requirements are satisfied, the input array is returned instead of a copy.

Returns**arr_t**

[ndarray] Unless *copy* is False and the other conditions for returning the input array are satisfied (see description for *copy* input parameter), *arr_t* is a new array of the same shape as the input array, with dtype, order given by *dtype*, *order*.

Raises**ComplexWarning**

When casting from complex to float or int. To avoid this, one should use `a.real.astype(t)`.

ValueError

When casting using 'same_value' and the values change or would overflow

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 2.5])
>>> x
array([1. ,  2. ,  2.5])
```

```
>>> x.astype(np.int_)
array([1, 2, 2])
```

```
>>> x.astype(np.int_, casting="same_value")
Traceback (most recent call last):
...
ValueError: could not cast 'same_value' double to long
```

```
>>> x[:2].astype(np.int_, casting="same_value")
array([1, 2])
```

method

`ndarray.byteswap` (*inplace=False*)

Swap the bytes of the array elements

Toggle between low-endian and big-endian data representation by returning a byteswapped array, optionally swapped in-place. Arrays of byte-strings are not swapped. The real and imaginary parts of a complex number are swapped individually.

Parameters**inplace**

[bool, optional] If `True`, swap bytes in-place, default is `False`.

Returns**out**

[ndarray] The byteswapped array. If `inplace` is `True`, this is a view to self.

Examples

```
>>> import numpy as np
>>> A = np.array([1, 256, 8755], dtype=np.int16)
>>> list(map(hex, A))
['0x1', '0x100', '0x2233']
>>> A.byteswap(inplace=True)
array([ 256,      1, 13090], dtype=int16)
>>> list(map(hex, A))
['0x100', '0x1', '0x3322']
```

Arrays of byte-strings are not swapped

```
>>> A = np.array([b'ceg', b'fac'])
>>> A.byteswap()
array([b'ceg', b'fac'], dtype='|S3')
```

`A.view(A.dtype.newbyteorder()).byteswap()` produces an array with the same values but different representation in memory

```
>>> A = np.array([1, 2, 3], dtype=np.int64)
>>> A.view(np.uint8)
array([1, 0, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0, 0, 0, 0, 3, 0, 0, 0, 0, 0,
       0, 0], dtype=uint8)
>>> A.view(A.dtype.newbyteorder()).byteswap(inplace=True)
array([1, 2, 3], dtype='>i8')
>>> A.view(np.uint8)
array([0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0, 0, 0,
       0, 3], dtype=uint8)
```

method

`ndarray.choose` (*choices*, *out=None*, *mode='raise'*)

Use an index array to construct a new array from a set of choices.

Refer to [numpy.choose](#) for full documentation.

See also:

[numpy.choose](#)

equivalent function

method

`ndarray.clip` (*min=<no value>*, *max=<no value>*, *out=None*, ***kwargs*)

Return an array whose values are limited to `[min, max]`. One of `max` or `min` must be given.

Refer to [numpy.clip](#) for full documentation.

See also:

[`numpy.clip`](#)
equivalent function

method

`ndarray.compress` (*condition*, *axis=None*, *out=None*)

Return selected slices of this array along given axis.

Refer to [`numpy.compress`](#) for full documentation.

See also:

[`numpy.compress`](#)
equivalent function

method

`ndarray.conj` ()

Complex-conjugate all elements.

Refer to [`numpy.conjugate`](#) for full documentation.

See also:

[`numpy.conjugate`](#)
equivalent function

method

`ndarray.conjugate` ()

Return the complex conjugate, element-wise.

Refer to [`numpy.conjugate`](#) for full documentation.

See also:

[`numpy.conjugate`](#)
equivalent function

method

`ndarray.copy` (*order='C'*)

Return a copy of the array.

Parameters

order

[['C', 'F', 'A', 'K'], optional] Controls the memory layout of the copy. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *a* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *a* as closely as possible. (Note that this function and [`numpy.copy`](#) are very similar but have different default values for their *order=* arguments, and this function always passes sub-classes through.)

See also:

[`numpy.copy`](#)
Similar function with different default behavior

*numpy.copyto***Notes**

This function is the preferred method for creating an array copy. The function *numpy.copy* is similar, but it defaults to using order 'K', and will not pass sub-classes through by default.

Examples

```
>>> import numpy as np
>>> x = np.array([[1,2,3],[4,5,6]], order='F')
```

```
>>> y = x.copy()
```

```
>>> x.fill(0)
```

```
>>> x
array([[0, 0, 0],
       [0, 0, 0]])
```

```
>>> y
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> y.flags['C_CONTIGUOUS']
True
```

For arrays containing Python objects (e.g. `dtype=np.object_`), the copy is a shallow one. The new array will contain the same object which may lead to surprises if that object can be modified (is mutable):

```
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> b = a.copy()
>>> b[2][0] = 10
>>> a
array([1, 'm', list([10, 3, 4])], dtype=object)
```

To ensure all elements within an object array are copied, use *copy.deepcopy*:

```
>>> import copy
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> c = copy.deepcopy(a)
>>> c[2][0] = 10
>>> c
array([1, 'm', list([10, 3, 4])], dtype=object)
>>> a
array([1, 'm', list([2, 3, 4])], dtype=object)
```

method

`ndarray.cumprod` (*axis=None, dtype=None, out=None*)

Return the cumulative product of the elements along the given axis.

Refer to *numpy.cumprod* for full documentation.

See also:

[*numpy.cumprod*](#)
equivalent function

method

`ndarray.cumsum` (*axis=None, dtype=None, out=None*)

Return the cumulative sum of the elements along the given axis.

Refer to [*numpy.cumsum*](#) for full documentation.

See also:

[*numpy.cumsum*](#)
equivalent function

method

`ndarray.diagonal` (*offset=0, axis1=0, axis2=1*)

Return specified diagonals. In NumPy 1.9 the returned array is a read-only view instead of a copy as in previous NumPy versions. In a future version the read-only restriction will be removed.

Refer to [*numpy.diagonal*](#) for full documentation.

See also:

[*numpy.diagonal*](#)
equivalent function

method

`ndarray.dot` (*other, /, out=None*)

Refer to [*numpy.dot*](#) for full documentation.

See also:

[*numpy.dot*](#)
equivalent function

method

`ndarray.dump` (*file*)

Dump a pickle of the array to the specified file. The array can be read back with `pickle.load` or `numpy.load`.

Parameters

file
[str or Path] A string naming the dump file.

method

`ndarray.dumps` ()

Returns the pickle of the array as a string. `pickle.loads` will convert the string back to an array.

Parameters

None

method

`ndarray.fill(value)`

Fill the array with a scalar value.

Parameters

value

[scalar] All elements of *a* will be assigned this value.

Examples

```
>>> import numpy as np
>>> a = np.array([1, 2])
>>> a.fill(0)
>>> a
array([0, 0])
>>> a = np.empty(2)
>>> a.fill(1)
>>> a
array([1., 1.])
```

Fill expects a scalar value and always behaves the same as assigning to a single array element. The following is a rare example where this distinction is important:

```
>>> a = np.array([None, None], dtype=np.object_)
>>> a[0] = np.array(3)
>>> a
array([array(3), None], dtype=object)
>>> a.fill(np.array(3))
>>> a
array([array(3), array(3)], dtype=object)
```

Where other forms of assignments will unpack the array being assigned:

```
>>> a[...] = np.array(3)
>>> a
array([3, 3], dtype=object)
```

method

`ndarray.flatten(order='C')`

Return a copy of the array collapsed into one dimension.

Parameters

order

[[‘C’, ‘F’, ‘A’, ‘K’], optional] ‘C’ means to flatten in row-major (C-style) order. ‘F’ means to flatten in column-major (Fortran- style) order. ‘A’ means to flatten in column-major order if *a* is Fortran *contiguous* in memory, row-major order otherwise. ‘K’ means to flatten *a* in the order the elements occur in memory. The default is ‘C’.

Returns

y

[ndarray] A copy of the input array, flattened to one dimension.

See also:

[`ravel`](#)

Return a flattened array.

flat

A 1-D flat iterator over the array.

Examples

```
>>> import numpy as np
>>> a = np.array([[1,2], [3,4]])
>>> a.flatten()
array([1, 2, 3, 4])
>>> a.flatten('F')
array([1, 3, 2, 4])
```

method

`ndarray.getfield(dtype, offset=0)`

Returns a field of the given array as a certain type.

A field is a view of the array data with a given data-type. The values in the view are determined by the given type and the offset into the current array in bytes. The offset needs to be such that the view dtype fits in the array dtype; for example an array of dtype `complex128` has 16-byte elements. If taking a view with a 32-bit integer (4 bytes), the offset needs to be between 0 and 12 bytes.

Parameters**dtype**

[str or dtype] The data type of the view. The dtype size of the view can not be larger than that of the array itself.

offset

[int] Number of bytes to skip before beginning the element view.

Examples

```
>>> import numpy as np
>>> x = np.diag([1.+1.j]*2)
>>> x[1, 1] = 2 + 4.j
>>> x
array([[1.+1.j,  0.+0.j],
       [0.+0.j,  2.+4.j]])
>>> x.getfield(np.float64)
array([[1.,  0.],
       [0.,  2.]])
```

By choosing an offset of 8 bytes we can select the complex part of the array for our view:

```
>>> x.getfield(np.float64, offset=8)
array([[1.,  0.],
       [0.,  4.]])
```

method

`ndarray.item(*args)`

Copy an element of an array to a standard Python scalar and return it.

Parameters

***args**

[Arguments (variable number and type)]

- **none**: in this case, the method only works for arrays with one element (*a.size == 1*), which element is copied into a standard Python scalar object and returned.
- **int_type**: this argument is interpreted as a flat index into the array, specifying which element to copy and return.
- **tuple of int_types**: functions as does a single **int_type** argument, except that the argument is interpreted as an nd-index into the array.

Returns**z**

[Standard Python scalar object] A copy of the specified element of the array as a suitable Python scalar

Notes

When the data type of *a* is `longdouble` or `clongdouble`, `item()` returns a scalar array object because there is no available Python scalar that would not lose information. Void arrays return a buffer object for `item()`, unless fields are defined, in which case a tuple is returned.

`item` is very similar to `a[args]`, except, instead of an array scalar, a standard Python scalar is returned. This can be useful for speeding up access to elements of the array and doing arithmetic on elements of the array using Python's optimized math.

Examples

```
>>> import numpy as np
>>> np.random.seed(123)
>>> x = np.random.randint(9, size=(3, 3))
>>> x
array([[2, 2, 6],
       [1, 3, 6],
       [1, 0, 1]])
>>> x.item(3)
1
>>> x.item(7)
0
>>> x.item((0, 1))
2
>>> x.item((2, 2))
1
```

For an array with object dtype, elements are returned as-is.

```
>>> a = np.array([np.int64(1)], dtype=np.object_)
>>> a.item() #return np.int64
np.int64(1)
```

method

`ndarray.max` (*axis=None*, *out=None*, ***, *keepdims=<no value>*, *initial=<no value>*, *where=<no value>*)

Return the maximum along a given axis.

Refer to `numpy.amax` for full documentation.

See also:

[`numpy.amax`](#)

equivalent function

method

`ndarray.mean` (*axis=None, dtype=None, out=None, *, keepdims=<no value>, where=<no value>*)

Returns the average of the array elements along given axis.

Refer to [`numpy.mean`](#) for full documentation.

See also:

[`numpy.mean`](#)

equivalent function

method

`ndarray.min` (*axis=None, out=None, *, keepdims=<no value>, initial=<no value>, where=<no value>*)

Return the minimum along a given axis.

Refer to [`numpy.amin`](#) for full documentation.

See also:

[`numpy.amin`](#)

equivalent function

method

`ndarray.nonzero` ()

Return the indices of the elements that are non-zero.

Refer to [`numpy.nonzero`](#) for full documentation.

See also:

[`numpy.nonzero`](#)

equivalent function

method

`ndarray.partition` (*kth, axis=-1, kind='introselect', order=None*)

Partially sorts the elements in the array in such a way that the value of the element in k-th position is in the position it would be in a sorted array. In the output array, all elements smaller than the k-th element are located to the left of this element and all equal or greater are located to its right. The ordering of the elements in the two partitions on the either side of the k-th element in the output array is undefined.

Parameters

kth

[int or sequence of ints] Element index to partition by. The kth element value will be in its final sorted position and all smaller elements will be moved before it and all equal or greater elements behind it. The order of all elements in the partitions is undefined. If provided with a sequence of kth it will partition all elements indexed by kth of them into their sorted position at once.

Deprecated since version 1.22.0: Passing booleans as index is deprecated.

axis

[int, optional] Axis along which to sort. Default is -1, which means sort along the last axis.

kind

[{'introspect'}, optional] Selection algorithm. Default is 'introspect'.

order

[str or list of str, optional] When *a* is an array with fields defined, this argument specifies which fields to compare first, second, etc. A single field can be specified as a string, and not all fields need to be specified, but unspecified fields will still be used, in the order in which they come up in the dtype, to break ties.

See also:

[*numpy.partition*](#)

Return a partitioned copy of an array.

[*argpartition*](#)

Indirect partition.

[*sort*](#)

Full sort.

Notes

See `np.partition` for notes on the different algorithms.

Examples

```
>>> import numpy as np
>>> a = np.array([3, 4, 2, 1])
>>> a.partition(3)
>>> a
array([2, 1, 3, 4]) # may vary
```

```
>>> a.partition((1, 3))
>>> a
array([1, 2, 3, 4])
```

method

`ndarray.prod` (*axis=None*, *dtype=None*, *out=None*, *, *keepdims=<no value>*, *initial=<no value>*, *where=<no value>*)

Return the product of the array elements over the given axis

Refer to [*numpy.prod*](#) for full documentation.

See also:

[*numpy.prod*](#)

equivalent function

method

`ndarray.put` (*indices, values, mode='raise'*)

Set `a.flat[n] = values[n]` for all `n` in indices.

Refer to [`numpy.put`](#) for full documentation.

See also:

[`numpy.put`](#)

equivalent function

method

`ndarray.ravel` (*order='C'*)

Return a flattened array.

Refer to [`numpy.ravel`](#) for full documentation.

See also:

[`numpy.ravel`](#)

equivalent function

[`ndarray.flat`](#)

a flat iterator on the array.

method

`ndarray.repeat` (*repeats, axis=None*)

Repeat elements of an array.

Refer to [`numpy.repeat`](#) for full documentation.

See also:

[`numpy.repeat`](#)

equivalent function

method

`ndarray.reshape` (*shape, /, *, order='C', copy=None*) *a.reshape(*shape, order='C', copy=None)*

`ndarray.reshape` (**shape, order='C', copy=None*) → `None`

Returns an array containing the same data with a new shape.

Refer to [`numpy.reshape`](#) for full documentation.

See also:

[`numpy.reshape`](#)

equivalent function

Notes

Unlike the free function `numpy.reshape`, this method on `ndarray` allows the elements of the shape parameter to be passed in as separate arguments. For example, `a.reshape(4, 2)` is equivalent to `a.reshape((4, 2))`.

method

`ndarray.resize(new_shape, /, *, refcheck=True)` *a.resize(*new_shape, refcheck=True)*

`ndarray.resize(*new_shape, refcheck=True) → None`

Change shape and size of array in-place.

Parameters

new_shape

[tuple of ints, or *n* ints] Shape of resized array.

refcheck

[bool, optional] If False, reference count will not be checked. Default is True. See Notes below for more explanation.

Returns

None

Raises

ValueError

If *a* does not own its own data or references or views to may exist.

See also:

`resize`

Return a new array with the specified shape.

Notes

This reallocates space for the data area if necessary.

Only contiguous arrays (data elements consecutive in memory) can be resized.

Reallocating arrays in-place can often lead to memory fragmentation and should be avoided. If the goal is to reclaim over-allocated memory, alternatives are to create a view or a copy of just the desired data, or using two passes to build the array: one to cheaply determine the shape and another to allocate and fill. Benchmark your use case to determine what is optimum. You may be surprised to find `resize` actually slows down or bloats your application.

The purpose of the reference count check is to make sure you do not use this array as a buffer for another Python object and then reallocate the memory.

On Python 3.13 and older, the check allows objects with exactly one reference to be reallocated in-place. On Python 3.14 and newer, the array must be uniquely referenced. See [1] for more details.

If you are sure that you have not shared the memory for this array with another Python object, then you may safely set `refcheck` to False.

References

[1]

Examples

Shrinking an array: array is flattened (in the order that the data are stored in memory), resized, and reshaped:

```
>>> import numpy as np
```

```
>>> a = np.array([[0, 1], [2, 3]], order='C')
>>> a.resize((2, 1))
>>> a
array([[0],
       [1]])
```

```
>>> a = np.array([[0, 1], [2, 3]], order='F')
>>> a.resize((2, 1))
>>> a
array([[0],
       [2]])
```

Enlarging an array: as above, but missing entries are filled with zeros:

```
>>> b = np.array([[0, 1], [2, 3]])
>>> b.resize(2, 3) # new_shape parameter doesn't have to be a tuple
>>> b
array([[0, 1, 2],
       [3, 0, 0]])
```

Referencing an array prevents resizing...

```
>>> c = a
>>> a.resize((1, 1))
Traceback (most recent call last):
...
ValueError: cannot resize an array that references or is referenced ...
```

Unless *refcheck* is False:

```
>>> a.resize((1, 1), refcheck=False)
>>> a
array([[0]])
>>> c
array([[0]])
```

method

`ndarray.round` (*decimals=0, out=None*)

Return *a* with each element rounded to the given number of decimals.

Refer to *numpy.around* for full documentation.

See also:

numpy.around
equivalent function

method

`ndarray.searchsorted(v, side='left', sorter=None)`

Find indices where elements of *v* should be inserted in *a* to maintain order.

For full documentation, see [numpy.searchsorted](#).

See also:

[numpy.searchsorted](#)

equivalent function

method

`ndarray.setfield(val, dtype, offset=0)`

Put a value into a specified place in a field defined by a data-type.

Place *val* into *a*'s field defined by *dtype* and beginning *offset* bytes into the field.

Parameters

val

[object] Value to be placed in field.

dtype

[dtype object] Data-type of the field in which to place *val*.

offset

[int, optional] The number of bytes into the field at which to place *val*.

Returns

None

See also:

[getfield](#)

Examples

```
>>> import numpy as np
>>> x = np.eye(3)
>>> x.getfield(np.float64)
array([[1.,  0.,  0.],
       [0.,  1.,  0.],
       [0.,  0.,  1.]])
>>> x.setfield(3, np.int32)
>>> x.getfield(np.int32)
array([[3, 3, 3],
       [3, 3, 3],
       [3, 3, 3]], dtype=int32)
>>> x
array([[1.0e+000, 1.5e-323, 1.5e-323],
       [1.5e-323, 1.0e+000, 1.5e-323],
       [1.5e-323, 1.5e-323, 1.0e+000]])
>>> x.setfield(np.eye(3), np.int32)
>>> x
array([[1.,  0.,  0.],
       [0.,  1.,  0.],
       [0.,  0.,  1.]])
```

method

`ndarray.setflags` (*write=None, align=None, uic=None*)

Set array flags WRITEABLE, ALIGNED, WRITEBACKIFCOPY, respectively.

These Boolean-valued flags affect how numpy interprets the memory area used by *a* (see Notes below). The ALIGNED flag can only be set to True if the data is actually aligned according to the type. The WRITEBACKIFCOPY flag can never be set to True. The flag WRITEABLE can only be set to True if the array owns its own memory, or the ultimate owner of the memory exposes a writeable buffer interface, or is a string. (The exception for string is made so that unpickling can be done without copying memory.)

Parameters

write

[bool, optional] Describes whether or not *a* can be written to.

align

[bool, optional] Describes whether or not *a* is aligned properly for its type.

uic

[bool, optional] Describes whether or not *a* is a copy of another “base” array.

Notes

Array flags provide information about how the memory area used for the array is to be interpreted. There are 7 Boolean flags in use, only three of which can be changed by the user: WRITEBACKIFCOPY, WRITEABLE, and ALIGNED.

WRITEABLE (W) the data area can be written to;

ALIGNED (A) the data and strides are aligned appropriately for the hardware (as determined by the compiler);

WRITEBACKIFCOPY (X) this array is a copy of some other array (referenced by `.base`). When the C-API function `PyArray_ResolveWritebackIfCopy` is called, the base array will be updated with the contents of this array.

All flags can be accessed using the single (upper case) letter as well as the full name.

Examples

```
>>> import numpy as np
>>> y = np.array([[3, 1, 7],
...               [2, 0, 0],
...               [8, 5, 9]])
>>> y
array([[3, 1, 7],
       [2, 0, 0],
       [8, 5, 9]])
>>> y.flags
C_CONTIGUOUS : True
F_CONTIGUOUS : False
OWNDATA : True
WRITEABLE : True
ALIGNED : True
WRITEBACKIFCOPY : False
>>> y.setflags(write=0, align=0)
```

(continues on next page)

(continued from previous page)

```

>>> y.flags
C_CONTIGUOUS : True
F_CONTIGUOUS : False
OWNDATA : True
WRITEABLE : False
ALIGNED : False
WRITEBACKIFCOPY : False
>>> y.setflags(uic=1)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: cannot set WRITEBACKIFCOPY flag to True

```

method

`ndarray.sort` (*axis=-1, kind=None, order=None, *, stable=None, descending=None*)

Sort an array in-place. Refer to [`numpy.sort`](#) for full documentation.

Parameters

axis

[int, optional] Axis along which to sort. Default is -1, which means sort along the last axis.

kind

[{'quicksort', 'mergesort', 'heapsort', 'stable'}, optional] Sorting algorithm. The default is 'quicksort'. Note that both 'stable' and 'mergesort' use timsort under the covers and, in general, the actual implementation will vary with datatype. The 'mergesort' option is retained for backwards compatibility.

order

[str or list of str, optional] When *a* is an array with fields defined, this argument specifies which fields to compare first, second, etc. A single field can be specified as a string, and not all fields need be specified, but unspecified fields will still be used, in the order in which they come up in the dtype, to break ties.

stable

[bool, optional] Sort stability. If `True`, the returned array will maintain the relative order of a values which compare as equal. If `False` or `None`, this is not guaranteed. Internally, this option selects `kind='stable'`. Default: `None`.

New in version 2.0.0.

See also:

[`numpy.sort`](#)

Return a sorted copy of an array.

[`numpy.argsort`](#)

Indirect sort.

[`numpy.lexsort`](#)

Indirect stable sort on multiple keys.

[`numpy.searchsorted`](#)

Find elements in sorted array.

[`numpy.partition`](#)

Partial sort.

Notes

See `numpy.sort` for notes on the different sorting algorithms.

Examples

```
>>> import numpy as np
>>> a = np.array([[1,4], [3,1]])
>>> a.sort(axis=1)
>>> a
array([[1, 4],
       [1, 3]])
>>> a.sort(axis=0)
>>> a
array([[1, 3],
       [1, 4]])
```

Use the `order` keyword to specify a field to use when sorting a structured array:

```
>>> a = np.array([('a', 2), ('c', 1)], dtype=[('x', 'S1'), ('y', int)])
>>> a.sort(order='y')
>>> a
array([(b'c', 1), (b'a', 2)],
      dtype=[('x', 'S1'), ('y', '<i8')])
```

method

`ndarray.squeeze` (*axis=None*)

Remove axes of length one from *a*.

Refer to `numpy.squeeze` for full documentation.

See also:

`numpy.squeeze`
equivalent function

method

`ndarray.std` (*axis=None, dtype=None, out=None, ddof=0, *, keepdims=<no value>, where=<no value>, mean=<no value>*)

Returns the standard deviation of the array elements along given axis.

Refer to `numpy.std` for full documentation.

See also:

`numpy.std`
equivalent function

method

`ndarray.sum` (*axis=None, dtype=None, out=None, *, keepdims=<no value>, initial=<no value>, where=<no value>*)

Return the sum of the array elements over the given axis.

Refer to `numpy.sum` for full documentation.

See also:[`numpy.sum`](#)

equivalent function

method

`ndarray.swapaxes` (*axis1*, *axis2*, /)Return a view of the array with *axis1* and *axis2* interchanged.Refer to [`numpy.swapaxes`](#) for full documentation.**See also:**[`numpy.swapaxes`](#)

equivalent function

method

`ndarray.take` (*indices*, *axis=None*, *out=None*, *mode='raise'*)Return an array formed from the elements of *a* at the given indices.Refer to [`numpy.take`](#) for full documentation.**See also:**[`numpy.take`](#)

equivalent function

method

`ndarray.to_device` (*device*, /, *, *stream=None*)

For Array API compatibility. Since NumPy only supports CPU arrays, this method is a no-op that returns the same array.

Parameters**device**

["cpu"] Must be "cpu".

stream

[None, optional] Currently unsupported.

Returns**out**

[Self] Returns the same array.

method

`ndarray.tobytes` (*order='C'*)

Construct Python bytes containing the raw data bytes in the array.

Constructs Python bytes showing a copy of the raw contents of data memory. The bytes object is produced in C-order by default. This behavior is controlled by the `order` parameter.**Parameters****order**[['C', 'F', 'A'], optional] Controls the memory layout of the bytes object. 'C' means C-order, 'F' means F-order, 'A' (short for *Any*) means 'F' if *a* is Fortran contiguous, 'C' otherwise. Default is 'C'.

Returns

s
[bytes] Python bytes exhibiting a copy of *a*'s raw data.

See also:*frombuffer*

Inverse of this operation, construct a 1-dimensional array from Python bytes.

Examples

```
>>> import numpy as np
>>> x = np.array([[0, 1], [2, 3]], dtype='<u2')
>>> x.tobytes()
b'\x00\x00\x01\x00\x02\x00\x03\x00'
>>> x.tobytes('C') == x.tobytes()
True
>>> x.tobytes('F')
b'\x00\x00\x02\x00\x01\x00\x03\x00'
```

method

`ndarray.tofile(fid, /, sep='', format='%s')`

Write array to a file as text or binary (default).

Data is always written in 'C' order, independent of the order of *a*. The data produced by this method can be recovered using the function `fromfile()`.

Parameters**fid**

[file or str or Path] An open file object, or a string containing a filename.

sep

[str] Separator between array items for text output. If "" (empty), a binary file is written, equivalent to `file.write(a.tobytes())`.

format

[str] Format string for text file output. Each entry in the array is formatted to text by first converting it to the closest Python type, and then using "format" % item.

Notes

This is a convenience function for quick storage of array data. Information on endianness and precision is lost, so this method is not a good choice for files intended to archive data or transport data between machines with different endianness. Some of these problems can be overcome by outputting the data as text files, at the expense of speed and file size.

When *fid* is a file object, array contents are directly written to the file, bypassing the file object's `write` method. As a result, `tofile` cannot be used with files objects supporting compression (e.g., `GzipFile`) or file-like objects that do not support `fileno()` (e.g., `BytesIO`).

method

`ndarray.tolist()`

Return the array as an `a.ndim`-levels deep nested list of Python scalars.

Return a copy of the array data as a (nested) Python list. Data items are converted to the nearest compatible builtin Python type, via the *item* method.

If `a.ndim` is 0, then since the depth of the nested list is 0, it will not be a list at all, but a simple Python scalar.

Parameters

none

Returns

y

[object, or list of object, or list of list of object, or ...] The possibly nested list of array elements.

Notes

The array may be recreated via `a = np.array(a.tolist())`, although this may sometimes lose precision.

Examples

For a 1D array, `a.tolist()` is almost the same as `list(a)`, except that `tolist` changes numpy scalars to Python scalars:

```
>>> import numpy as np
>>> a = np.uint32([1, 2])
>>> a_list = list(a)
>>> a_list
[np.uint32(1), np.uint32(2)]
>>> type(a_list[0])
<class 'numpy.uint32'>
>>> a_tolist = a.tolist()
>>> a_tolist
[1, 2]
>>> type(a_tolist[0])
<class 'int'>
```

Additionally, for a 2D array, `tolist` applies recursively:

```
>>> a = np.array([[1, 2], [3, 4]])
>>> list(a)
[array([1, 2]), array([3, 4])]
>>> a.tolist()
[[1, 2], [3, 4]]
```

The base case for this recursion is a 0D array:

```
>>> a = np.array(1)
>>> list(a)
Traceback (most recent call last):
...
TypeError: iteration over a 0-d array
```

(continues on next page)

(continued from previous page)

```
>>> a.tolist()  
1
```

method

`ndarray.trace` (*offset=0, axis1=0, axis2=1, dtype=None, out=None*)

Return the sum along diagonals of the array.

Refer to [`numpy.trace`](#) for full documentation.

See also:

[`numpy.trace`](#)

equivalent function

method

`ndarray.transpose` (**axes*)

Returns a view of the array with axes transposed.

Refer to [`numpy.transpose`](#) for full documentation.

Parameters

axes

[None, tuple of ints, or *n* ints]

- None or no argument: reverses the order of the axes.
- tuple of ints: *i* in the *j*-th place in the tuple means that the array's *i*-th axis becomes the transposed array's *j*-th axis.
- *n* ints: same as an *n*-tuple of the same ints (this form is intended simply as a “convenience” alternative to the tuple form).

Returns

p

[ndarray] View of the array with its axes suitably permuted.

See also:

[`transpose`](#)

Equivalent function.

[`ndarray.T`](#)

Array property returning the array transposed.

[`ndarray.reshape`](#)

Return a reshaped ndarray without changing data.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> a
array([[1, 2],
       [3, 4]])
>>> a.transpose()
array([[1, 3],
       [2, 4]])
>>> a.transpose((1, 0))
array([[1, 3],
       [2, 4]])
>>> a.transpose(1, 0)
array([[1, 3],
       [2, 4]])
```

```
>>> a = np.array([1, 2, 3, 4])
>>> a
array([1, 2, 3, 4])
>>> a.transpose()
array([1, 2, 3, 4])
```

method

`ndarray.var` (*axis=None*, *dtype=None*, *out=None*, *ddof=0*, *, *keepdims=<no value>*, *where=<no value>*, *mean=<no value>*)

Returns the variance of the array elements, along given axis.

Refer to [`numpy.var`](#) for full documentation.

See also:

[`numpy.var`](#)

equivalent function

method

`ndarray.view` (*[dtype][, type]*)

New view of array with the same data.

Note: Passing `None` for `dtype` is different from omitting the parameter, since the former invokes `dtype(None)` which is an alias for `dtype(np.float64)`.

Parameters

`dtype`

[data-type or ndarray sub-class, optional] Data-type descriptor of the returned view, e.g., `float32` or `int16`. Omitting it results in the view having the same data-type as *a*. This argument can also be specified as an ndarray sub-class, which then specifies the type of the returned object (this is equivalent to setting the `type` parameter).

`type`

[Python type, optional] Type of the returned view, e.g., ndarray or matrix. Again, omission of the parameter results in type preservation.

Notes

`a.view()` is used two different ways:

`a.view(some_dtype)` or `a.view(dtype=some_dtype)` constructs a view of the array's memory with a different data-type. This can cause a reinterpretation of the bytes of memory.

`a.view(ndarray_subclass)` or `a.view(type=ndarray_subclass)` just returns an instance of `ndarray_subclass` that looks at the same array (same shape, dtype, etc.) This does not cause a reinterpretation of the memory.

For `a.view(some_dtype)`, if `some_dtype` has a different number of bytes per entry than the previous dtype (for example, converting a regular array to a structured array), then the last axis of `a` must be contiguous. This axis will be resized in the result.

Changed in version 1.23.0: Only the last axis needs to be contiguous. Previously, the entire array had to be C-contiguous.

Examples

```
>>> import numpy as np
>>> x = np.array([(-1, 2)], dtype=[('a', np.int8), ('b', np.int8)])
```

Viewing array data using a different type and dtype:

```
>>> nonneg = np.dtype(["a", np.uint8], ("b", np.uint8)])
>>> y = x.view(dtype=nonneg, type=np.recarray)
>>> x["a"]
array([-1], dtype=int8)
>>> y.a
array([255], dtype=uint8)
```

Creating a view on a structured array so it can be used in calculations

```
>>> x = np.array([(1, 2), (3, 4)], dtype=[('a', np.int8), ('b', np.int8)])
>>> xv = x.view(dtype=np.int8).reshape(-1, 2)
>>> xv
array([[1, 2],
       [3, 4]], dtype=int8)
>>> xv.mean(0)
array([2., 3.])
```

Making changes to the view changes the underlying array

```
>>> xv[0, 1] = 20
>>> x
array([(1, 20), (3, 4)], dtype=[('a', 'i1'), ('b', 'i1')])
```

Using a view to convert an array to a recarray:

```
>>> z = x.view(np.recarray)
>>> z.a
array([1, 3], dtype=int8)
```

Views share data:

```
>>> x[0] = (9, 10)
>>> z[0]
np.record((9, 10), dtype=[('a', 'i1'), ('b', 'i1')])
```

Views that change the dtype size (bytes per entry) should normally be avoided on arrays defined by slices, transposes, fortran-ordering, etc.:

```
>>> x = np.array([[1, 2, 3], [4, 5, 6]], dtype=np.int16)
>>> y = x[:, ::2]
>>> y
array([[1, 3],
       [4, 6]], dtype=int16)
>>> y.view(dtype=[('width', np.int16), ('length', np.int16)])
Traceback (most recent call last):
...
ValueError: To change to a dtype of a different size, the last axis must be
↳contiguous
>>> z = y.copy()
>>> z.view(dtype=[('width', np.int16), ('length', np.int16)])
array([[1, 3],
       [4, 6]], dtype=[('width', '<i2'), ('length', '<i2')])
```

However, views that change dtype are totally fine for arrays with a contiguous last axis, even if the rest of the axes are not C-contiguous:

```
>>> x = np.arange(2 * 3 * 4, dtype=np.int8).reshape(2, 3, 4)
>>> x.transpose(1, 0, 2).view(np.int16)
array([[[ 256,  770],
        [3340, 3854]],

       [[1284, 1798],
        [4368, 4882]],

       [[2312, 2826],
        [5396, 5910]]], dtype=int16)
```

See also:

array

Construct an array.

zeros

Create an array, each element of which is zero.

empty

Create an array, but leave its allocated memory unchanged (i.e., it contains “garbage”).

dtype

Create a data-type.

numpy.typing.NDArray

An ndarray alias *generic* w.r.t. its *dtype.type*.

Notes

There are two modes of creating an array using `__new__`:

1. If *buffer* is None, then only *shape*, *dtype*, and *order* are used.
2. If *buffer* is an object exposing the buffer interface, then all keywords are interpreted.

No `__init__` method is needed because the array is fully initialized after the `__new__` method.

Examples

These examples illustrate the low-level *ndarray* constructor. Refer to the *See Also* section above for easier ways of constructing an ndarray.

First mode, *buffer* is None:

```
>>> import numpy as np
>>> np.ndarray(shape=(2,2), dtype=np.float64, order='F')
array([[0.0e+000, 0.0e+000], # random
       [      nan, 2.5e-323]])
```

Second mode:

```
>>> np.ndarray((2,), buffer=np.array([1,2,3]),
...           offset=np.int_().itemsize,
...           dtype=np.int_) # offset = 1*itemsize, i.e. skip first element
array([2, 3])
```

Indexing arrays

Arrays can be indexed using an extended Python slicing syntax, `array[selection]`. Similar syntax is also used for accessing fields in a structured data type.

See also:

Array Indexing.

Internal memory layout of an ndarray

An instance of class *ndarray* consists of a contiguous one-dimensional segment of computer memory (owned by the array, or by some other object), combined with an indexing scheme that maps *N* integers into the location of an item in the block. The ranges in which the indices can vary is specified by the *shape* of the array. How many bytes each item takes and how the bytes are interpreted is defined by the *data-type object* associated with the array.

A segment of memory is inherently 1-dimensional, and there are many different schemes for arranging the items of an *N*-dimensional array in a 1-dimensional block. NumPy is flexible, and *ndarray* objects can accommodate any *strided indexing scheme*. In a strided scheme, the *N*-dimensional index $(n_0, n_1, \dots, n_{N-1})$ corresponds to the offset (in bytes):

$$n_{\text{offset}} = \sum_{k=0}^{N-1} s_k n_k$$

from the beginning of the memory block associated with the array. Here, s_k are integers which specify the *strides* of the array. The column-major order (used, for example, in the Fortran language and in *Matlab*) and row-major order

(used in C) schemes are just specific kinds of strided scheme, and correspond to memory that can be *addressed* by the strides:

$$s_k^{\text{column}} = \text{itemsize} \prod_{j=0}^{k-1} d_j, \quad s_k^{\text{row}} = \text{itemsize} \prod_{j=k+1}^{N-1} d_j.$$

where $d_j = \text{self.shape}[j]$.

Both the C and Fortran orders are contiguous, *i.e.*, single-segment, memory layouts, in which every part of the memory block can be accessed by some combination of the indices.

Note: *Contiguous arrays* and *single-segment arrays* are synonymous and are used interchangeably throughout the documentation.

While a C-style and Fortran-style contiguous array, which has the corresponding flags set, can be addressed with the above strides, the actual strides may be different. This can happen in two cases:

1. If `self.shape[k] == 1` then for any legal index `index[k] == 0`. This means that in the formula for the offset $n_k = 0$ and thus $s_k n_k = 0$ and the value of $s_k = \text{self.strides}[k]$ is arbitrary.
2. If an array has no elements (`self.size == 0`) there is no legal index and the strides are never used. Any array with no elements may be considered C-style and Fortran-style contiguous.

Point 1. means that `self` and `self.squeeze()` always have the same contiguity and `aligned` flags value. This also means that even a high dimensional array could be C-style and Fortran-style contiguous at the same time.

An array is considered aligned if the memory offsets for all elements and the base offset itself is a multiple of `self.itemsize`. Understanding *memory-alignment* leads to better performance on most hardware.

Warning: It does *not* generally hold that `self.strides[-1] == self.itemsize` for C-style contiguous arrays or `self.strides[0] == self.itemsize` for Fortran-style contiguous arrays is true.

Data in new *ndarrays* is in the row-major (C) order, unless otherwise specified, but, for example, *basic array slicing* often produces views in a different scheme.

Note: Several algorithms in NumPy work on arbitrarily strided arrays. However, some algorithms require single-segment arrays. When an irregularly strided array is passed in to such algorithms, a copy is automatically made.

Array attributes

Array attributes reflect information that is intrinsic to the array itself. Generally, accessing an array through its attributes allows you to get and sometimes set intrinsic properties of the array without creating a new array. The exposed attributes are the core parts of an array and only some of them can be reset meaningfully without creating a new array. Information on each attribute is given below.

Memory layout

The following attributes contain information about the memory layout of the array:

<code>ndarray.flags</code>	Information about the memory layout of the array.
<code>ndarray.shape</code>	Tuple of array dimensions.
<code>ndarray.strides</code>	Tuple of bytes to step in each dimension when traversing an array.
<code>ndarray.ndim</code>	Number of array dimensions.
<code>ndarray.data</code>	Python buffer object pointing to the start of the array's data.
<code>ndarray.size</code>	Number of elements in the array.
<code>ndarray.itemsize</code>	Length of one array element in bytes.
<code>ndarray.nbytes</code>	Total bytes consumed by the elements of the array.
<code>ndarray.base</code>	Base object if memory is from some other object.

attribute

`ndarray.flags`

Information about the memory layout of the array.

Attributes

C_CONTIGUOUS (C)

The data is in a single, C-style contiguous segment.

F_CONTIGUOUS (F)

The data is in a single, Fortran-style contiguous segment.

OWNDATA (O)

The array owns the memory it uses or borrows it from another object.

WRITEABLE (W)

The data area can be written to. Setting this to False locks the data, making it read-only. A view (slice, etc.) inherits WRITEABLE from its base array at creation time, but a view of a writeable array may be subsequently locked while the base array remains writeable. (The opposite is not true, in that a view of a locked array may not be made writeable. However, currently, locking a base object does not lock any views that already reference it, so under that circumstance it is possible to alter the contents of a locked array via a previously created writeable view onto it.) Attempting to change a non-writeable array raises a RuntimeError exception.

ALIGNED (A)

The data and all elements are aligned appropriately for the hardware.

WRITEBACKIFCOPY (X)

This array is a copy of some other array. The C-API function `PyArray_ResolveWritebackIfCopy` must be called before deallocating to the base array will be updated with the contents of this array.

FNC

F_CONTIGUOUS and not C_CONTIGUOUS.

FORC

F_CONTIGUOUS or C_CONTIGUOUS (one-segment test).

BEHAVED (B)

ALIGNED and WRITEABLE.

CARRAY (CA)

BEHAVED and C_CONTIGUOUS.

FARRAY (FA)

BEHAVED and F_CONTIGUOUS and not C_CONTIGUOUS.

Notes

The `flags` object can be accessed dictionary-like (as in `a.flags['WRITEABLE']`), or by using lowercased attribute names (as in `a.flags.writeable`). Short flag names are only supported in dictionary access.

Only the `WRITEBACKIFCOPY`, `WRITEABLE`, and `ALIGNED` flags can be changed by the user, via direct assignment to the attribute or dictionary entry, or by calling `ndarray.setflags`.

The array flags cannot be set arbitrarily:

- `WRITEBACKIFCOPY` can only be set `False`.
- `ALIGNED` can only be set `True` if the data is truly aligned.
- `WRITEABLE` can only be set `True` if the array owns its own memory or the ultimate owner of the memory exposes a writeable buffer interface or is a string.

Arrays can be both C-style and Fortran-style contiguous simultaneously. This is clear for 1-dimensional arrays, but can also be true for higher dimensional arrays.

Even for contiguous arrays a stride for a given dimension `arr.strides[dim]` may be *arbitrary* if `arr.shape[dim] == 1` or the array has no elements. It does *not* generally hold that `self.strides[-1] == self.itemsize` for C-style contiguous arrays or `self.strides[0] == self.itemsize` for Fortran-style contiguous arrays is true.

attribute

`ndarray.shape`

Tuple of array dimensions.

The shape property is usually used to get the current shape of an array, but may also be used to reshape the array in-place by assigning a tuple of array dimensions to it. As with `numpy.reshape`, one of the new shape dimensions can be -1, in which case its value is inferred from the size of the array and the remaining dimensions. Reshaping an array in-place will fail if a copy is required.

Warning: Setting `arr.shape` is deprecated and may be removed in the future. Using `ndarray.reshape` is the preferred approach.

See also:

`numpy.shape`

Equivalent getter function.

`numpy.reshape`

Function similar to setting shape.

`ndarray.reshape`

Method similar to setting shape.

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 3, 4])
>>> x.shape
(4,)
>>> y = np.zeros((2, 3, 4))
>>> y.shape
(2, 3, 4)
```

attribute

`ndarray.strides`

Tuple of bytes to step in each dimension when traversing an array.

The byte offset of element $(i[0], i[1], \dots, i[n])$ in an array a is:

```
offset = sum(np.array(i) * a.strides)
```

A more detailed explanation of strides can be found in *The N-dimensional array (ndarray)*.

Warning: Setting `arr.strides` is discouraged and may be deprecated in the future. `numpy.lib.stride_tricks.as_strided` should be preferred to create a new view of the same data in a safer way.

See also:

`numpy.lib.stride_tricks.as_strided`

Notes

Imagine an array of 32-bit integers (each 4 bytes):

```
x = np.array([[0, 1, 2, 3, 4],
              [5, 6, 7, 8, 9]], dtype=np.int32)
```

This array is stored in memory as 40 bytes, one after the other (known as a contiguous block of memory). The strides of an array tell us how many bytes we have to skip in memory to move to the next position along a certain axis. For example, we have to skip 4 bytes (1 value) to move to the next column, but 20 bytes (5 values) to get to the same position in the next row. As such, the strides for the array x will be $(20, 4)$.

Examples

```
>>> import numpy as np
>>> y = np.reshape(np.arange(2 * 3 * 4, dtype=np.int32), (2, 3, 4))
>>> y
array([[[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]],
       [[12, 13, 14, 15],
        [16, 17, 18, 19],
        [20, 21, 22, 23]]], dtype=np.int32)
>>> y.strides
```

(continues on next page)

(continued from previous page)

```
(48, 16, 4)
>>> y[1, 1, 1]
np.int32(17)
>>> offset = sum(y.strides * np.array((1, 1, 1)))
>>> offset // y.itemsize
np.int64(17)
```

```
>>> x = np.reshape(np.arange(5*6*7*8, dtype=np.int32), (5, 6, 7, 8))
>>> x = x.transpose(2, 3, 1, 0)
>>> x.strides
(32, 4, 224, 1344)
>>> i = np.array([3, 5, 2, 2], dtype=np.int32)
>>> offset = sum(i * x.strides)
>>> x[3, 5, 2, 2]
np.int32(813)
>>> offset // x.itemsize
np.int64(813)
```

attribute

`ndarray.ndim`

Number of array dimensions.

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 3])
>>> x.ndim
1
>>> y = np.zeros((2, 3, 4))
>>> y.ndim
3
```

attribute

`ndarray.data`

Python buffer object pointing to the start of the array's data.

attribute

`ndarray.size`

Number of elements in the array.

Equal to `np.prod(a.shape)`, i.e., the product of the array's dimensions.

Notes

a.size returns a standard arbitrary precision Python integer. This may not be the case with other methods of obtaining the same value (like the suggested `np.prod(a.shape)`, which returns an instance of `np.int_`), and may be relevant if the value is used further in calculations that may overflow a fixed size integer type.

Examples

```
>>> import numpy as np
>>> x = np.zeros((3, 5, 2), dtype=np.complex128)
>>> x.size
30
>>> np.prod(x.shape)
30
```

attribute

`ndarray.itemsize`

Length of one array element in bytes.

Examples

```
>>> import numpy as np
>>> x = np.array([1,2,3], dtype=np.float64)
>>> x.itemsize
8
>>> x = np.array([1,2,3], dtype=np.complex128)
>>> x.itemsize
16
```

attribute

`ndarray.nbytes`

Total bytes consumed by the elements of the array.

See also:

`sys.getsizeof`

Memory consumed by the object itself without parents in case view. This does include memory consumed by non-element attributes.

Notes

Does not include memory consumed by non-element attributes of the array object.

Examples

```
>>> import numpy as np
>>> x = np.zeros((3,5,2), dtype=np.complex128)
>>> x.nbytes
480
>>> np.prod(x.shape) * x.itemsize
480
```

attribute

`ndarray.base`

Base object if memory is from some other object.

Examples

The base of an array that owns its memory is None:

```
>>> import numpy as np
>>> x = np.array([1,2,3,4])
>>> x.base is None
True
```

Slicing creates a view, whose memory is shared with x:

```
>>> y = x[2:]
>>> y.base is x
True
```

Data type

See also:

Data type objects

The data type object associated with the array can be found in the `dtype` attribute:

<code>ndarray.dtype</code>	Data-type of the array's elements.
----------------------------	------------------------------------

attribute

`ndarray.dtype`

Data-type of the array's elements.

Warning: Setting `arr.dtype` is discouraged and may be deprecated in the future. Setting will replace the `dtype` without modifying the memory (see also `ndarray.view` and `ndarray.astype`).

Parameters

None

Returns

`d`

[numpy dtype object]

See also:

[ndarray.astype](#)

Cast the values contained in the array to a new data-type.

[ndarray.view](#)

Create a view of the same data but a different data-type.

[numpy.dtype](#)

Examples

```
>>> import numpy as np
>>> x = np.arange(4).reshape((2, 2))
>>> x
array([[0, 1],
       [2, 3]])
>>> x.dtype
dtype('int64')    # may vary (OS, bitness)
>>> isinstance(x.dtype, np.dtype)
True
```

Other attributes

<i>ndarray.T</i>	View of the transposed array.
<i>ndarray.real</i>	The real part of the array.
<i>ndarray.imag</i>	The imaginary part of the array.
<i>ndarray.flat</i>	A 1-D iterator over the array.

attribute

`ndarray.T`

View of the transposed array.

Same as `self.transpose()`.

See also:

[transpose](#)

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> a
array([[1, 2],
       [3, 4]])
>>> a.T
array([[1, 3],
       [2, 4]])
```

```
>>> a = np.array([1, 2, 3, 4])
>>> a
array([1, 2, 3, 4])
>>> a.T
array([1, 2, 3, 4])
```

attribute

`ndarray.real`

The real part of the array.

Usually returns a view into the original array, but returns elementwise `.real` for arrays of objects.

See also:

[*numpy.real*](#)

equivalent function

Examples

```
>>> import numpy as np
>>> x = np.sqrt([1+0j, 0+1j])
>>> x.real
array([ 1.          ,  0.70710678])
>>> x.real.dtype
dtype('float64')
```

attribute

`ndarray.imag`

The imaginary part of the array.

Returns a view into the original array for complex arrays. For non-complex arrays, returns a zero array of the same dtype. For object arrays returns elementwise `.imag` or 0 if `.imag` is undefined.

Examples

```
>>> import numpy as np
>>> x = np.sqrt([1+0j, 0+1j])
>>> x.imag
array([ 0.          ,  0.70710678])
>>> x.imag.dtype
dtype('float64')
```

attribute

`ndarray.flat`

A 1-D iterator over the array.

This is a [*numpy.flatiter*](#) instance, which acts similarly to, but is not a subclass of, Python's built-in iterator object.

See also:

[*flatten*](#)

Return a copy of the array collapsed into one dimension.

flatiter

Examples

```
>>> import numpy as np
>>> x = np.arange(1, 7).reshape(2, 3)
>>> x
array([[1, 2, 3],
       [4, 5, 6]])
>>> x.flat[3]
4
>>> x.T
array([[1, 4],
       [2, 5],
       [3, 6]])
>>> x.T.flat[3]
5
>>> type(x.flat)
<class 'numpy.flatiter'>
```

An assignment example:

```
>>> x.flat = 3; x
array([[3, 3, 3],
       [3, 3, 3]])
>>> x.flat[[1,4]] = 1; x
array([[3, 1, 3],
       [3, 1, 3]])
```

Array interface

See also:

The array interface protocol.

<code>__array_interface__</code>	Python-side of the array interface
<code>__array_struct__</code>	C-side of the array interface

ctypes foreign function interface

<code>ndarray.ctypes</code>	An object to simplify the interaction of the array with the ctypes module.
-----------------------------	--

attribute

`ndarray.ctypes`

An object to simplify the interaction of the array with the ctypes module.

This attribute creates an object that makes it easier to use arrays when calling shared libraries with the ctypes module. The returned object has, among others, data, shape, and strides attributes (see Notes below) which themselves return ctypes objects that can be used as arguments to a shared library.

Parameters

None

Returns**c**

[Python object] Possessing attributes data, shape, strides, etc.

See also:*numpy.ctypeslib***Notes**

Below are the public attributes of this object which were documented in “Guide to NumPy” (we have omitted undocumented public attributes, as well as documented private attributes):

`_ctypes.data`

A pointer to the memory area of the array as a Python integer. This memory area may contain data that is not aligned, or not in correct byte-order. The memory area may not even be writeable. The array flags and data-type of this array should be respected when passing this attribute to arbitrary C-code to avoid trouble that can include Python crashing. User Beware! The value of this attribute is exactly the same as: `self._array_interface_['data'][0]`.

Note that unlike `data_as`, a reference won't be kept to the array: code like `ctypes.c_void_p((a + b).ctypes.data)` will result in a pointer to a deallocated array, and should be spelt `(a + b).ctypes.data_as(ctypes.c_void_p)`

`_ctypes.shape`

(`c_intp*self.ndim`): A ctypes array of length `self.ndim` where the basetype is the C-integer corresponding to `dtype('p')` on this platform (see `c_intp`). This base-type could be `ctypes.c_int`, `ctypes.c_long`, or `ctypes.c_longlong` depending on the platform. The ctypes array contains the shape of the underlying array.

`_ctypes.strides`

(`c_intp*self.ndim`): A ctypes array of length `self.ndim` where the basetype is the same as for the shape attribute. This ctypes array contains the strides information from the underlying array. This strides information is important for showing how many bytes must be jumped to get to the next element in the array.

`_ctypes.data_as(obj)`

Return the data pointer cast to a particular c-types object. For example, calling `self._as_parameter_` is equivalent to `self.data_as(ctypes.c_void_p)`. Perhaps you want to use the data as a pointer to a ctypes array of floating-point data: `self.data_as(ctypes.POINTER(ctypes.c_double))`.

The returned pointer will keep a reference to the array.

`_ctypes.shape_as(obj)`

Return the shape tuple as an array of some other c-types type. For example: `self.shape_as(ctypes.c_short)`.

`_ctypes.strides_as(obj)`

Return the strides tuple as an array of some other c-types type. For example: `self.strides_as(ctypes.c_longlong)`.

If the ctypes module is not available, then the ctypes attribute of array objects still returns something useful, but ctypes objects are not returned and errors may be raised instead. In particular, the object will still have the `as_parameter` attribute which will return an integer equal to the data attribute.

Examples

```
>>> import numpy as np
>>> import ctypes
>>> x = np.array([[0, 1], [2, 3]], dtype=np.int32)
>>> x
array([[0, 1],
       [2, 3]], dtype=int32)
>>> x.ctypes.data
31962608 # may vary
>>> x.ctypes.data_as(ctypes.POINTER(ctypes.c_uint32))
<__main__.LP_c_uint object at 0x7ff2fc1fc200> # may vary
>>> x.ctypes.data_as(ctypes.POINTER(ctypes.c_uint32)).contents
c_uint(0)
>>> x.ctypes.data_as(ctypes.POINTER(ctypes.c_uint64)).contents
c_ulong(4294967296)
>>> x.ctypes.shape
<numpy._core._internal.c_long_Array_2 object at 0x7ff2fc1fce60> # may vary
>>> x.ctypes.strides
<numpy._core._internal.c_long_Array_2 object at 0x7ff2fc1ff320> # may vary
```

Array methods

An *ndarray* object has many methods which operate on or with the array in some fashion, typically returning an array result. These methods are briefly explained below. (Each method's docstring has a more complete description.)

For the following methods there are also corresponding functions in *numpy*: *all*, *any*, *argmax*, *argmin*, *argpartition*, *argsort*, *choose*, *clip*, *compress*, *copy*, *cumprod*, *cumsum*, *diagonal*, *imag*, *max*, *mean*, *min*, *nonzero*, *partition*, *prod*, *put*, *ravel*, *real*, *repeat*, *reshape*, *round*, *searchsorted*, *sort*, *squeeze*, *std*, *sum*, *swapaxes*, *take*, *trace*, *transpose*, *var*.

Array conversion

<code>ndarray.item(*args)</code>	Copy an element of an array to a standard Python scalar and return it.
<code>ndarray.tolist()</code>	Return the array as an a.ndim-levels deep nested list of Python scalars.
<code>ndarray.tobytes([order])</code>	Construct Python bytes containing the raw data bytes in the array.
<code>ndarray.tofile(fid, /[, sep, format])</code>	Write array to a file as text or binary (default).
<code>ndarray.dump(file)</code>	Dump a pickle of the array to the specified file.
<code>ndarray.dumps()</code>	Returns the pickle of the array as a string.
<code>ndarray.astype(dtype[, order, casting, ...])</code>	Copy of the array, cast to a specified type.
<code>ndarray.byteswap(inplace)</code>	Swap the bytes of the array elements
<code>ndarray.copy([order])</code>	Return a copy of the array.
<code>ndarray.view([dtype][, type])</code>	New view of array with the same data.
<code>ndarray.getfield(dtype[, offset])</code>	Returns a field of the given array as a certain type.
<code>ndarray.setflags([write, align, uic])</code>	Set array flags WRITEABLE, ALIGNED, WRITEBACKIFCOPY, respectively.
<code>ndarray.fill(value)</code>	Fill the array with a scalar value.

Shape manipulation

For reshape, resize, and transpose, the single tuple argument may be replaced with *n* integers which will be interpreted as an *n*-tuple.

<code>ndarray.reshape(a.reshape)</code>	Returns an array containing the same data with a new shape.
<code>ndarray.resize(a.resize)</code>	Change shape and size of array in-place.
<code>ndarray.transpose(*axes)</code>	Returns a view of the array with axes transposed.
<code>ndarray.swapaxes(axis1, axis2, /)</code>	Return a view of the array with <i>axis1</i> and <i>axis2</i> interchanged.
<code>ndarray.flatten([order])</code>	Return a copy of the array collapsed into one dimension.
<code>ndarray.ravel([order])</code>	Return a flattened array.
<code>ndarray.squeeze([axis])</code>	Remove axes of length one from <i>a</i> .

Item selection and manipulation

For array methods that take an *axis* keyword, it defaults to *None*. If *axis* is *None*, then the array is treated as a 1-D array. Any other value for *axis* represents the dimension along which the operation should proceed.

<code>ndarray.take(indices[, axis, out, mode])</code>	Return an array formed from the elements of <i>a</i> at the given indices.
<code>ndarray.put(indices, values[, mode])</code>	Set <code>a.flat[n] = values[n]</code> for all <i>n</i> in indices.
<code>ndarray.repeat(repeats[, axis])</code>	Repeat elements of an array.
<code>ndarray.choose(choices[, out, mode])</code>	Use an index array to construct a new array from a set of choices.
<code>ndarray.sort([axis, kind, order, stable, ...])</code>	Sort an array in-place.
<code>ndarray.argsort([axis, kind, order, stable, ...])</code>	Returns the indices that would sort this array.
<code>ndarray.partition(kth[, axis, kind, order])</code>	Partially sorts the elements in the array in such a way that the value of the element in <i>k</i> -th position is in the position it would be in a sorted array.
<code>ndarray.argpartition(kth[, axis, kind, order])</code>	Returns the indices that would partition this array.
<code>ndarray.searchsorted(v[, side, sorter])</code>	Find indices where elements of <i>v</i> should be inserted in <i>a</i> to maintain order.
<code>ndarray.nonzero()</code>	Return the indices of the elements that are non-zero.
<code>ndarray.compress(condition[, axis, out])</code>	Return selected slices of this array along given axis.
<code>ndarray.diagonal([offset, axis1, axis2])</code>	Return specified diagonals.

Calculation

Many of these methods take an argument named *axis*. In such cases,

- If *axis* is *None* (the default), the array is treated as a 1-D array and the operation is performed over the entire array. This behavior is also the default if *self* is a 0-dimensional array or array scalar. (An array scalar is an instance of the types/classes float32, float64, etc., whereas a 0-dimensional array is an ndarray instance containing precisely one array scalar.)
- If *axis* is an integer, then the operation is done over the given axis (for each 1-D subarray that can be created along the given axis).

Example of the *axis* argument

A 3-dimensional array of size 3 x 3 x 3, summed over each of its three axes:

```
>>> import numpy as np
```

```
>>> x = np.arange(27).reshape((3,3,3))
>>> x
array([[[ 0,  1,  2],
        [ 3,  4,  5],
        [ 6,  7,  8]],
       [[ 9, 10, 11],
        [12, 13, 14],
        [15, 16, 17]],
       [[18, 19, 20],
        [21, 22, 23],
        [24, 25, 26]]])
>>> x.sum(axis=0)
array([[27, 30, 33],
       [36, 39, 42],
       [45, 48, 51]])
>>> # for sum, axis is the first keyword, so we may omit it,
>>> # specifying only its value
>>> x.sum(0), x.sum(1), x.sum(2)
(array([[27, 30, 33],
        [36, 39, 42],
        [45, 48, 51]]),
 array([[ 9, 12, 15],
        [36, 39, 42],
        [63, 66, 69]]),
 array([[ 3, 12, 21],
        [30, 39, 48],
        [57, 66, 75]]))
```

The parameter *dtype* specifies the data type over which a reduction operation (like summing) should take place. The default reduce data type is the same as the data type of *self*. To avoid overflow, it can be useful to perform the reduction using a larger data type.

For several methods, an optional *out* argument can also be provided and the result will be placed into the output array given. The *out* argument must be an *ndarray* and have the same number of elements. It can have a different data type in which case casting will be performed.

<code>ndarray.max([axis, out, keepdims, initial, ...])</code>	Return the maximum along a given axis.
<code>ndarray.argmax([axis, out, keepdims])</code>	Return indices of the maximum values along the given axis.
<code>ndarray.min([axis, out, keepdims, initial, ...])</code>	Return the minimum along a given axis.
<code>ndarray.argmin([axis, out, keepdims])</code>	Return indices of the minimum values along the given axis.
<code>ndarray.clip([min, max, out])</code>	Return an array whose values are limited to <code>[min, max]</code> .
<code>ndarray.conj()</code>	Complex-conjugate all elements.
<code>ndarray.round([decimals, out])</code>	Return <code>a</code> with each element rounded to the given number of decimals.
<code>ndarray.trace([offset, axis1, axis2, dtype, out])</code>	Return the sum along diagonals of the array.
<code>ndarray.sum([axis, dtype, out, keepdims, ...])</code>	Return the sum of the array elements over the given axis.
<code>ndarray.cumsum([axis, dtype, out])</code>	Return the cumulative sum of the elements along the given axis.
<code>ndarray.mean([axis, dtype, out, keepdims, where])</code>	Returns the average of the array elements along given axis.
<code>ndarray.var([axis, dtype, out, ddof, ...])</code>	Returns the variance of the array elements, along given axis.
<code>ndarray.std([axis, dtype, out, ddof, ...])</code>	Returns the standard deviation of the array elements along given axis.
<code>ndarray.prod([axis, dtype, out, keepdims, ...])</code>	Return the product of the array elements over the given axis
<code>ndarray.cumprod([axis, dtype, out])</code>	Return the cumulative product of the elements along the given axis.
<code>ndarray.all([axis, out, keepdims, where])</code>	Returns True if all elements evaluate to True.
<code>ndarray.any([axis, out, keepdims, where])</code>	Returns True if any of the elements of <code>a</code> evaluate to True.

Arithmetic, matrix multiplication, and comparison operations

Arithmetic and comparison operations on *ndarrays* are defined as element-wise operations, and generally yield *ndarray* objects as results.

Each of the arithmetic operations (+, -, *, /, //, %, `divmod()`, ** or `pow()`, <<, >>, &, ^, |, ~) and the comparisons (==, <, >, <=, >=, !=) is equivalent to the corresponding universal function (or ufunc for short) in NumPy. For more information, see the section on *Universal Functions*.

Comparison operators:

<code>ndarray.__lt__(value, /)</code>	Return self<value.
<code>ndarray.__le__(value, /)</code>	Return self<=value.
<code>ndarray.__gt__(value, /)</code>	Return self>value.
<code>ndarray.__ge__(value, /)</code>	Return self>=value.
<code>ndarray.__eq__(value, /)</code>	Return self==value.
<code>ndarray.__ne__(value, /)</code>	Return self!=value.

method

`ndarray.__lt__(value, /)`

Return self<value.

method

`ndarray.__le__(value, /)`

Return `self <= value`.

method

`ndarray.__gt__(value, /)`

Return `self > value`.

method

`ndarray.__ge__(value, /)`

Return `self >= value`.

method

`ndarray.__eq__(value, /)`

Return `self == value`.

method

`ndarray.__ne__(value, /)`

Return `self != value`.

Truth value of an array (`bool()`):

<code>ndarray.__bool__()</code>	True if self else False
---------------------------------	-------------------------

method

`ndarray.__bool__()`

True if self else False

Note: Truth-value testing of an array invokes `ndarray.__bool__`, which raises an error if the number of elements in the array is not 1, because the truth value of such arrays is ambiguous. Use `.any()` and `.all()` instead to be clear about what is meant in such cases. (If you wish to check for whether an array is empty, use for example `.size > 0`.)

Unary operations:

<code>ndarray.__neg__()</code>	<code>-self</code>
<code>ndarray.__pos__()</code>	<code>+self</code>
<code>ndarray.__abs__(self)</code>	
<code>ndarray.__invert__()</code>	<code>~self</code>

method

`ndarray.__neg__()`

`-self`

method

`ndarray.__pos__()`

`+self`

method

`ndarray.__abs__(self)`

method

`ndarray.__invert__()`
`~self`

Arithmetic:

<code>ndarray.__add__(value, /)</code>	Return self+value.
<code>ndarray.__sub__(value, /)</code>	Return self-value.
<code>ndarray.__mul__(value, /)</code>	Return self*value.
<code>ndarray.__truediv__(value, /)</code>	Return self/value.
<code>ndarray.__floordiv__(value, /)</code>	Return self//value.
<code>ndarray.__mod__(value, /)</code>	Return self%value.
<code>ndarray.__divmod__(value, /)</code>	Return divmod(self, value).
<code>ndarray.__pow__(value[, mod])</code>	Return pow(self, value, mod).
<code>ndarray.__lshift__(value, /)</code>	Return self<<value.
<code>ndarray.__rshift__(value, /)</code>	Return self>>value.
<code>ndarray.__and__(value, /)</code>	Return self&value.
<code>ndarray.__or__(value, /)</code>	Return self value.
<code>ndarray.__xor__(value, /)</code>	Return self^value.

method

`ndarray.__add__(value, /)`
 Return self+value.

method

`ndarray.__sub__(value, /)`
 Return self-value.

method

`ndarray.__mul__(value, /)`
 Return self*value.

method

`ndarray.__truediv__(value, /)`
 Return self/value.

method

`ndarray.__floordiv__(value, /)`
 Return self//value.

method

`ndarray.__mod__(value, /)`
 Return self%value.

method

`ndarray.__divmod__(value, /)`
 Return divmod(self, value).

method

`ndarray.__pow__ (value, mod=None, /)`

Return `pow(self, value, mod)`.

method

`ndarray.__lshift__ (value, /)`

Return `self<<value`.

method

`ndarray.__rshift__ (value, /)`

Return `self>>value`.

method

`ndarray.__and__ (value, /)`

Return `self&value`.

method

`ndarray.__or__ (value, /)`

Return `self|value`.

method

`ndarray.__xor__ (value, /)`

Return `self^value`.

Note:

- Any third argument to `pow` is silently ignored, as the underlying `ufunc` takes only two arguments.
 - Because `ndarray` is a built-in type (written in C), the `__r{op}__` special methods are not directly defined.
 - The functions called to implement many arithmetic special methods for arrays can be modified using `__array_ufunc__`.
-

Arithmetic, in-place:

<code>ndarray.__iadd__ (value, /)</code>	Return <code>self+=value</code> .
<code>ndarray.__isub__ (value, /)</code>	Return <code>self-=value</code> .
<code>ndarray.__imul__ (value, /)</code>	Return <code>self*=value</code> .
<code>ndarray.__itruediv__ (value, /)</code>	Return <code>self/=value</code> .
<code>ndarray.__ifloordiv__ (value, /)</code>	Return <code>self//=value</code> .
<code>ndarray.__imod__ (value, /)</code>	Return <code>self%=value</code> .
<code>ndarray.__ipow__ (value, /)</code>	Return <code>self**=value</code> .
<code>ndarray.__ilshift__ (value, /)</code>	Return <code>self<<=value</code> .
<code>ndarray.__irshift__ (value, /)</code>	Return <code>self>>=value</code> .
<code>ndarray.__iand__ (value, /)</code>	Return <code>self&=value</code> .
<code>ndarray.__ior__ (value, /)</code>	Return <code>self =value</code> .
<code>ndarray.__ixor__ (value, /)</code>	Return <code>self^=value</code> .

method

`ndarray.__iadd__ (value, /)`

Return `self+=value`.

method

`ndarray.__isub__ (value, /)`

Return `self-=value`.

method

`ndarray.__imul__ (value, /)`

Return `self*=value`.

method

`ndarray.__itruediv__ (value, /)`

Return `self/=value`.

method

`ndarray.__ifloordiv__ (value, /)`

Return `self//=value`.

method

`ndarray.__imod__ (value, /)`

Return `self%=value`.

method

`ndarray.__ipow__ (value, /)`

Return `self**=value`.

method

`ndarray.__ilshift__ (value, /)`

Return `self<<=value`.

method

`ndarray.__irshift__ (value, /)`

Return `self>>=value`.

method

`ndarray.__iand__ (value, /)`

Return `self&=value`.

method

`ndarray.__ior__ (value, /)`

Return `self|=value`.

method

`ndarray.__ixor__ (value, /)`

Return `self^=value`.

Warning: In place operations will perform the calculation using the precision decided by the data type of the two operands, but will silently downcast the result (if necessary) so it can fit back into the array. Therefore, for mixed precision calculations, `A {op}= B` can be different than `A = A {op} B`. For example, suppose `a = ones((3, 3))`. Then, `a += 3j` is different than `a = a + 3j`: while they both perform the same computation, `a += 3` casts the result to fit back in `a`, whereas `a = a + 3j` re-binds the name `a` to the result.

Matrix Multiplication:

<code>ndarray.__matmul__(value, /)</code>	Return <code>self@value</code> .
---	----------------------------------

method

`ndarray.__matmul__(value, /)`
Return `self@value`.

Note: Matrix operators `@` and `@=` were introduced in Python 3.5 following [PEP 465](#), and the `@` operator has been introduced in NumPy 1.10.0. Further information can be found in the [`matmul`](#) documentation.

Special methods

For standard library functions:

<code>ndarray.__copy__()</code>	Used if <code>copy.copy</code> is called on an array.
<code>ndarray.__deepcopy__(memo, /)</code>	Used if <code>copy.deepcopy</code> is called on an array.
<code>ndarray.__reduce__()</code>	For pickling.
<code>ndarray.__setstate__(state, /)</code>	For unpickling.

method

`ndarray.__copy__()`
Used if `copy.copy` is called on an array. Returns a copy of the array.
Equivalent to `a.copy(order='K')`.

method

`ndarray.__deepcopy__(memo, /)`
Used if `copy.deepcopy` is called on an array.

method

`ndarray.__reduce__()`
For pickling.

method

`ndarray.__setstate__(state, /)`
For unpickling.

The `state` argument must be a sequence that contains the following elements:

Parameters

version

[int] optional pickle version. If omitted defaults to 0.

shape

[tuple]

dtype

[data-type]

isFortran

[bool]

rawdata

[string or list] a binary string with the data (or a list if 'a' is an object array)

Basic customization:

`ndarray.__new__(*args, **kwargs)``ndarray.__array__([dtype], *, copy)`For `dtype` parameter it returns a new reference to self if `dtype` is not given or it matches array's data type.`ndarray.__array_wrap__(array[, context[, ...])`Returns a view of `array` with the same type as self.

method

`ndarray.__new__(*args, **kwargs)`

method

`ndarray.__array__([dtype], *, copy=None)`

For `dtype` parameter it returns a new reference to self if `dtype` is not given or it matches array's data type. A new array of provided data type is returned if `dtype` is different from the current data type of the array. For `copy` parameter it returns a new reference to self if `copy=False` or `copy=None` and copying isn't enforced by `dtype` parameter. The method returns a new array for `copy=True`, regardless of `dtype` parameter.

A more detailed explanation of the `__array__` interface can be found in `dunder_array.interface`.

method

`ndarray.__array_wrap__(array, [context, [return_scalar, ]])`Returns a view of `array` with the same type as self.Container customization: (see [Indexing](#))`ndarray.__len__()`Return `len(self)`.`ndarray.__getitem__(key, /)`Return `self[key]`.`ndarray.__setitem__(key, value, /)`Set `self[key]` to value.`ndarray.__contains__(key, /)`Return `bool(key in self)`.

method

`ndarray.__len__()`Return `len(self)`.

method

`ndarray.__getitem__(key, /)`Return `self[key]`.

method

`ndarray.__setitem__(key, value, /)`Set `self[key]` to value.

method

`ndarray.__contains__ (key, /)`

Return `bool(key in self)`.

Conversion; the operations `int()`, `float()` and `complex()`. They work only on arrays that have one element in them and return the appropriate scalar.

`ndarray.__int__(self)`

`ndarray.__float__(self)`

`ndarray.__complex__(self)`

method

`ndarray.__int__ (self)`

method

`ndarray.__float__ (self)`

method

`ndarray.__complex__ (self)`

String representations:

<code>ndarray.__str__ (/)</code>	Return <code>str(self)</code> .
<code>ndarray.__repr__ (/)</code>	Return <code>repr(self)</code> .

method

`ndarray.__str__ (/)`

Return `str(self)`.

method

`ndarray.__repr__ (/)`

Return `repr(self)`.

Utility method for typing:

<code>ndarray.__class_getitem__ (\$cls, item, /)</code>	<code>ndarray[shape, dtype]</code>
---	------------------------------------

method

`ndarray.__class_getitem__ ($cls, item, /)`

`ndarray[shape, dtype]`

Return a parametrized wrapper around the `ndarray` type.

New in version 1.22.

Returns

alias

[`types.GenericAlias`] A parametrized `ndarray` type.

See also:

PEP 585

Type hinting generics in standard collections.

`numpy.typing.NDArray`

An ndarray alias `generic` w.r.t. its `dtype.type`.

Examples

```
>>> import numpy as np
```

```
>>> np.ndarray[tuple[int], np.dtype[np.uint8]]
numpy.ndarray[tuple[int], numpy.dtype[numpy.uint8]]
```

Structural pattern matching

Arrays support **structural pattern matching**. The array is matched as a sequence, so you can unpack arrays along the first dimension in `match/case` statements:

```
>>> arr = np.array([[1, 2], [3, 4]])
>>> match arr:
...     case [row1, row2]:
...         print(f"row1={row1}, row2={row2}")
row1=[1 2], row2=[3 4]
```

Nested patterns work too, matching inner dimensions:

```
>>> match arr:
...     case [[a, b], [c, d]]:
...         print(f"a={a}, b={b}, c={c}, d={d}")
a=1, b=2, c=3, d=4
```

All ndarray subclasses inherit this behavior.

1.2.2 Scalars

Python defines only one type of a particular data class (there is only one integer type, one floating-point type, etc.). This can be convenient in applications that don't need to be concerned with all the ways data can be represented in a computer. For scientific computing, however, more control is often needed.

In NumPy, there are 24 new fundamental Python types to describe different types of scalars. These type descriptors are mostly based on the types available in the C language that CPython is written in, with several additional types compatible with Python's types.

Array scalars have the same attributes and methods as `ndarrays`.¹ This allows one to treat items of an array partly on the same footing as arrays, smoothing out rough edges that result when mixing scalar and array operations.

Array scalars live in a hierarchy (see the Figure below) of data types. They can be detected using the hierarchy: For example, `isinstance(val, np.generic)` will return `True` if `val` is an array scalar object. Alternatively, what kind of array scalar is present can be determined using other members of the data type hierarchy. Thus, for example `isinstance(val, np.complexfloating)` will return `True` if `val` is a complex valued type, while

¹ However, array scalars are immutable, so none of the array scalar attributes are settable.

`isinstance(val, np.flexible)` will return true if `val` is one of the flexible itemsize array types (`str_`, `bytes_`, `void`).

Fig. 2: **Figure:** Hierarchy of type objects representing the array data types. Not shown are the two integer types `intp` and `uintp` which are used for indexing (the same as the default integer since NumPy 2).

Built-in scalar types

The built-in scalar types are shown below. The C-like names are associated with character codes, which are shown in their descriptions. Use of the character codes, however, is discouraged.

Some of the scalar types are essentially equivalent to fundamental Python types and therefore inherit from them as well as from the generic array scalar type:

Array scalar type	Related Python type	Inherits?
<code>int_</code>	<code>int</code>	no
<code>double</code>	<code>float</code>	yes
<code>cdouble</code>	<code>complex</code>	yes
<code>bytes_</code>	<code>bytes</code>	yes
<code>str_</code>	<code>str</code>	yes
<code>bool_</code>	<code>bool</code>	no
<code>datetime64</code>	<code>datetime.datetime</code>	no
<code>timedelta64</code>	<code>datetime.timedelta</code>	no

The `bool_` data type is very similar to the Python `bool` but does not inherit from it because Python's `bool` does not allow itself to be inherited from, and on the C-level the size of the actual bool data is not the same as a Python Boolean scalar.

Warning: The `int_` type does **not** inherit from the built-in `int`, because type `int` is not a fixed-width integer type.

Tip: The default data type in NumPy is `double`.

class `numpy.generic`

Base class for numpy scalar types.

Class from which most (all?) numpy scalar types are derived. For consistency, exposes the same API as `ndarray`, despite many consequent attributes being either “get-only,” or completely irrelevant. This is the class from which it is strongly suggested users should derive custom scalar types.

class `numpy.number`

Abstract base class of all numeric scalar types.

Integer types

class `numpy.integer`

Abstract base class of all integer scalar types.

Note: The numpy integer types mirror the behavior of C integers, and can therefore be subject to overflow-errors.

Signed integer types

class `numpy.signedinteger`

Abstract base class of all signed integer scalar types.

class `numpy.byte`

`int8(value=0, /)` –

Signed integer type, compatible with C `char`.

Character code

`'b'`

Canonical name

`numpy.byte`

Alias on this platform (Linux x86_64)

`numpy.int8`: 8-bit signed integer (–128 to 127).

class `numpy.short`

`int16(value=0, /)` –

Signed integer type, compatible with C `short`.

Character code

`'h'`

Canonical name

`numpy.short`

Alias on this platform (Linux x86_64)

`numpy.int16`: 16-bit signed integer (–32_768 to 32_767).

class `numpy.intc`

`int32(value=0, /)` –

Signed integer type, compatible with C `int`.

Character code

`'i'`

Canonical name

`numpy.intc`

Alias on this platform (Linux x86_64)

`numpy.int32`: 32-bit signed integer (–2_147_483_648 to 2_147_483_647).

class `numpy.int_`

`int64(value=0, /)` –

Signed integer type, compatible with C `long`.

Character code

`'l'`

Canonical name

`numpy.long`

Alias on this platform (Linux x86_64)

`numpy.int64`: 64-bit signed integer (–9_223_372_036_854_775_808 to 9_223_372_036_854_775_807).

Alias on this platform (Linux x86_64)*numpy.intp*: Signed integer large enough to fit pointer, compatible with C `intptr_t`.`numpy.long`alias of *int_***class** `numpy.longlong` (*value=0, /*)Signed integer type, compatible with C `long long`.**Character code**

'q'

Unsigned integer types**class** `numpy.unsignedinteger`

Abstract base class of all unsigned integer scalar types.

class `numpy.ubyte``uint8`(*value=0, /*) –Unsigned integer type, compatible with C `unsigned char`.**Character code**

'B'

Canonical name*numpy.ubyte***Alias on this platform (Linux x86_64)***numpy.uint8*: 8-bit unsigned integer (0 to 255).**class** `numpy.ushort``uint16`(*value=0, /*) –Unsigned integer type, compatible with C `unsigned short`.**Character code**

'H'

Canonical name*numpy.ushort***Alias on this platform (Linux x86_64)***numpy.uint16*: 16-bit unsigned integer (0 to 65_535).**class** `numpy.uintc``uint32`(*value=0, /*) –Unsigned integer type, compatible with C `unsigned int`.**Character code**

'I'

Canonical name*numpy.uintc***Alias on this platform (Linux x86_64)***numpy.uint32*: 32-bit unsigned integer (0 to 4_294_967_295).

class `numpy.uint`

`uint64(value=0, /)` –

Unsigned integer type, 64bit on 64bit systems and 32bit on 32bit systems.

Character code

'L'

Canonical name

`numpy.uint`

Alias on this platform (Linux x86_64)

`numpy.uint64`: 64-bit unsigned integer (0 to 18_446_744_073_709_551_615).

Alias on this platform (Linux x86_64)

`numpy.uintp`: Unsigned integer large enough to fit pointer, compatible with C `uintptr_t`.

`numpy.ulong`

alias of `uint`

class `numpy.ulonglong` (`value=0, /`)

Unsigned integer type, compatible with C `unsigned long long`.

Character code

'Q'

Inexact types

class `numpy.inexact`

Abstract base class of all numeric scalar types with a (potentially) inexact representation of the values in its range, such as floating-point numbers.

Note: Inexact scalars are printed using the fewest decimal digits needed to distinguish their value from other values of the same datatype, by judicious rounding. See the `unique` parameter of `format_float_positional` and `format_float_scientific`.

This means that variables with equal binary values but whose datatypes are of different precisions may display differently:

```
>>> import numpy as np
```

```
>>> f16 = np.float16("0.1")
>>> f32 = np.float32(f16)
>>> f64 = np.float64(f32)
>>> f16 == f32 == f64
True
>>> f16, f32, f64
(0.1, 0.099975586, 0.0999755859375)
```

Note that none of these floats hold the exact value $\frac{1}{10}$; `f16` prints as `0.1` because it is as close to that value as possible, whereas the other types do not as they have more precision and therefore have closer values.

Conversely, floating-point scalars of different precisions which approximate the same decimal value may compare unequal despite printing identically:

```
>>> f16 = np.float16("0.1")
>>> f32 = np.float32("0.1")
>>> f64 = np.float64("0.1")
>>> f16 == f32 == f64
```

(continues on next page)

(continued from previous page)

```
False
>>> f16, f32, f64
(0.1, 0.1, 0.1)
```

Floating-point types

class `numpy.floating`

Abstract base class of all floating-point scalar types.

class `numpy.half`

`float16(value=0, /)` –

Half-precision floating-point number type.

Character code

'e'

Canonical name

`numpy.half`

Alias on this platform (Linux x86_64)

`numpy.float16`: 16-bit-precision floating-point number type: sign bit, 5 bits exponent, 10 bits mantissa.

class `numpy.single`

`float32(value=0, /)` –

Single-precision floating-point number type, compatible with C `float`.

Character code

'f'

Canonical name

`numpy.single`

Alias on this platform (Linux x86_64)

`numpy.float32`: 32-bit-precision floating-point number type: sign bit, 8 bits exponent, 23 bits mantissa.

class `numpy.double` (`x=0, /`)

`float64(value=0, /)` –

Double-precision floating-point number type, compatible with Python `float` and C `double`.

Character code

'd'

Canonical name

`numpy.double`

Alias on this platform (Linux x86_64)

`numpy.float64`: 64-bit precision floating-point number type: sign bit, 11 bits exponent, 52 bits mantissa.

class `numpy.longdouble` (`value=0, /`)

Extended-precision floating-point number type, compatible with C `long double` but not necessarily with IEEE 754 quadruple-precision.

Character code

'g'

Alias on this platform (Linux x86_64)

numpy.float128: 128-bit extended-precision floating-point number type.

Complex floating-point types**class** `numpy.complexfloating`

Abstract base class of all complex number scalar types that are made up of floating-point numbers.

class `numpy.csingle`

`complex64(real=0, imag=0, /)` –

Complex number type composed of two single-precision floating-point numbers.

Character code

'F'

Canonical name

numpy.csingle

Alias on this platform (Linux x86_64)

numpy.complex64: Complex number type composed of 2 32-bit-precision floating-point numbers.

class `numpy.cdouble` (*real=0, imag=0*)

`complex128(real=0, imag=0, /)` –

Complex number type composed of two double-precision floating-point numbers, compatible with Python `complex`.

Character code

'D'

Canonical name

numpy.cdouble

Alias on this platform (Linux x86_64)

numpy.complex128: Complex number type composed of 2 64-bit-precision floating-point numbers.

class `numpy.clongdouble` (*real=0, imag=0, /*)

Complex number type composed of two extended-precision floating-point numbers.

Character code

'G'

Alias on this platform (Linux x86_64)

numpy.complex256: Complex number type composed of 2 128-bit extended-precision floating-point numbers.

Other types

`numpy.bool_`

alias of `bool`

class `numpy.bool` (*value=False, /*)

Boolean type (True or False), stored as a byte.

Warning: The `bool` type is not a subclass of the `int_` type (the `bool` is not even a number type). This is different than Python's default implementation of `bool` as a sub-class of `int`.

Character code

'?'

class `numpy.datetime64` (*value=None, *args*)

If created from a 64-bit integer, it represents an offset from 1970-01-01T00:00:00. If created from string, the string can be in ISO 8601 date or datetime format.

When parsing a string to create a datetime object, if the string contains a trailing timezone (A 'Z' or a timezone offset), the timezone will be dropped and a User Warning is given.

Datetime64 objects should be considered to be UTC and therefore have an offset of +0000.

```
>>> np.datetime64(10, 'Y')
np.datetime64('1980')
>>> np.datetime64('1980', 'Y')
np.datetime64('1980')
>>> np.datetime64(10, 'D')
np.datetime64('1970-01-11')
```

See *Datetimes and timedeltas* for more information.

Character code

'M'

class `numpy.timedelta64` (*value=0, *args*)

A timedelta stored as a 64-bit integer.

See *Datetimes and timedeltas* for more information.

Character code

'm'

class `numpy.object_` (*value=None, /*)

Any Python object.

Character code

'O'

Note: The data actually stored in object arrays (*i.e.*, arrays having dtype `object_`) are references to Python objects, not the objects themselves. Hence, object arrays behave more like usual Python `lists`, in the sense that their contents need not be of the same Python type.

The object type is also special because an array containing `object_` items does not return an `object_` object on item access, but instead returns the actual object that the array item refers to.

The following data types are **flexible**: they have no predefined size and the data they describe can be of different length in different arrays. (In the character codes # is an integer denoting how many elements the data type consists of.)

class `numpy.flexible`

Abstract base class of all scalar types without predefined length. The actual size of these types depends on the specific `numpy.dtype` instantiation.

class `numpy.character`

Abstract base class of all character string scalar types.

class `numpy.bytes_` (*value=""*, **args*, ***kwargs*)

A byte string.

When used in arrays, this type strips trailing null bytes.

Character code

'S'

class `numpy.str_` (*value=""*, **args*, ***kwargs*)

A unicode string.

This type strips trailing null codepoints.

```
>>> s = np.str_("abc\x00")
>>> s
'abc'
```

Unlike the builtin `str`, this supports the [Buffer Protocol](#), exposing its contents as UCS4:

```
>>> m = memoryview(np.str_("abc"))
>>> m.format
'3w'
>>> m.tobytes()
b'a\x00\x00\x00b\x00\x00\x00c\x00\x00\x00'
```

Character code

'U'

class `numpy.void` (*length_or_data*, /, *dtype=None*)

Create a new structured or unstructured void scalar.

Parameters

length_or_data

[int, array-like, bytes-like, object] One of multiple meanings (see notes). The length or bytes data of an unstructured void. Or alternatively, the data to be stored in the new scalar when `dtype` is provided. This can be an array-like, in which case an array may be returned.

dtype

[dtype, optional] If provided the dtype of the new scalar. This dtype must be “void” dtype (i.e. a structured or unstructured void, see also [defining-structured-types](#)).

New in version 1.24.

Notes

For historical reasons and because void scalars can represent both arbitrary byte data and structured dtypes, the void constructor has three calling conventions:

1. **`np.void(5)` creates a `dtype="V5"` scalar filled with five `\0` bytes.** The 5 can be a Python or NumPy integer.
2. **`np.void(b"bytes-like")` creates a void scalar from the byte string.** The dtype itemsize will match the byte string length, here `"V10"`.
3. **When a `dtype=` is passed the call is roughly the same as an array creation.** However, a void scalar rather than array is returned.

Please see the examples which show all three different conventions.

Examples

```
>>> np.void(5)
np.void(b'\x00\x00\x00\x00\x00')
>>> np.void(b'abcd')
np.void(b'\x61\x62\x63\x64')
>>> np.void((3.2, b'eggs'), dtype="d,S5")
np.void((3.2, b'eggs'), dtype=[('f0', '<f8'), ('f1', 'S5')])
>>> np.void(3, dtype=[('x', np.int8), ('y', np.int8)])
np.void((3, 3), dtype=[('x', 'i1'), ('y', 'i1')])
```

Character code

'V'

Warning: Numeric Compatibility: If you used old typecode characters in your Numeric code (which was never recommended), you will need to change some of them to the new characters. In particular, the needed changes are `c` $\rightarrow$ `S1`, `b` $\rightarrow$ `B`, `l` $\rightarrow$ `b`, `s` $\rightarrow$ `h`, `w` $\rightarrow$ `H`, and `u` $\rightarrow$ `I`. These changes make the type character convention more consistent with other Python modules such as the `struct` module.

Sized aliases

Along with their (mostly) C-derived names, the integer, float, and complex data-types are also available using a bit-width convention so that an array of the right size can always be ensured. Two aliases (`numpy.intp` and `numpy.uintp`) pointing to the integer type that is sufficiently large to hold a C pointer are also provided.

`numpy.int8`

`numpy.int16`

`numpy.int32`

`numpy.int64`

Aliases for the signed integer types (one of `numpy.byte`, `numpy.short`, `numpy.intc`, `numpy.int_`, `numpy.long` and `numpy.longlong`) with the specified number of bits.

Compatible with the C99 `int8_t`, `int16_t`, `int32_t`, and `int64_t`, respectively.

`numpy.uint8`

`numpy.uint16`

`numpy.uint32`

numpy.uint64

Alias for the unsigned integer types (one of *numpy.ubyte*, *numpy.ushort*, *numpy.uintc*, *numpy.uint*, *numpy.ulong* and *numpy.ulonglong*) with the specified number of bits.

Compatible with the C99 `uint8_t`, `uint16_t`, `uint32_t`, and `uint64_t`, respectively.

numpy.intp

Alias for the signed integer type (one of *numpy.byte*, *numpy.short*, *numpy.intc*, *numpy.int_*, *numpy.long* and *numpy.longlong*) that is used as a default integer and for indexing.

Compatible with the C `Py_ssize_t`.

Character code

'n'

Changed in version 2.0: Before NumPy 2, this had the same size as a pointer. In practice this is almost always identical, but the character code 'p' maps to the C `intptr_t`. The character code 'n' was added in NumPy 2.0.

numpy.uintp

Alias for the unsigned integer type that is the same size as `intp`.

Compatible with the C `size_t`.

Character code

'N'

Changed in version 2.0: Before NumPy 2, this had the same size as a pointer. In practice this is almost always identical, but the character code 'P' maps to the C `uintptr_t`. The character code 'N' was added in NumPy 2.0.

numpy.float16

alias of *half*

numpy.float32

alias of *single*

numpy.float64

alias of *double*

numpy.float96**numpy.float128**

Alias for *numpy.longdouble*, named after its size in bits. The existence of these aliases depends on the platform.

numpy.complex64

alias of *csingle*

numpy.complex128

alias of *cdouble*

numpy.complex192**numpy.complex256**

Alias for *numpy.clongdouble*, named after its size in bits. The existence of these aliases depends on the platform.

Attributes

The array scalar objects have an *array priority* of `NPY_SCALAR_PRIORITY` (-1,000,000.0). They also do not (yet) have a *ctypes* attribute. Otherwise, they share the same attributes as arrays:

<code>generic.flags</code>	The integer value of flags.
<code>generic.shape</code>	Tuple of array dimensions.
<code>generic.strides</code>	Tuple of bytes steps in each dimension.
<code>generic.ndim</code>	The number of array dimensions.
<code>generic.data</code>	Pointer to start of data.
<code>generic.size</code>	The number of elements in the gentype.
<code>generic.itemsize</code>	The length of one element in bytes.
<code>generic.base</code>	Scalar attribute identical to <code>ndarray.base</code> .
<code>generic.dtype</code>	Get array data-descriptor.
<code>generic.real</code>	The real part of the scalar.
<code>generic.imag</code>	The imaginary part of the scalar.
<code>generic.flat</code>	A 1-D view of the scalar.
<code>generic.T</code>	Scalar attribute identical to <code>ndarray.T</code> .
<code>generic.__array_interface__</code>	Array protocol: Python side
<code>generic.__array_struct__</code>	Array protocol: struct
<code>generic.__array_priority__</code>	Array priority.
<code>generic.__array_wrap__</code>	<code>__array_wrap__</code> implementation for scalar types

attribute

`generic.flags`

The integer value of flags.

attribute

`generic.shape`

Tuple of array dimensions.

attribute

`generic.strides`

Tuple of bytes steps in each dimension.

attribute

`generic.ndim`

The number of array dimensions.

attribute

`generic.data`

Pointer to start of data.

attribute

`generic.size`

The number of elements in the gentype.

attribute

`generic.itemsize`

The length of one element in bytes.

attribute

`generic.base`

Scalar attribute identical to `ndarray.base`.

attribute

`generic.dtype`

Get array data-descriptor.

attribute

`generic.real`

The real part of the scalar.

attribute

`generic.imag`

The imaginary part of the scalar.

attribute

`generic.flat`

A 1-D view of the scalar.

attribute

`generic.T`

Scalar attribute identical to `ndarray.T`.

attribute

`generic.__array_interface__`

Array protocol: Python side

attribute

`generic.__array_struct__`

Array protocol: struct

attribute

`generic.__array_priority__`

Array priority.

method

`generic.__array_wrap__()`

`__array_wrap__` implementation for scalar types

Indexing

See also:

Indexing routines, Data type objects (dtype)

Array scalars can be indexed like 0-dimensional arrays: if *x* is an array scalar,

- `x[()]` returns a copy of array scalar
- `x[...]` returns a 0-dimensional `ndarray`

- `x['field-name']` returns the array scalar in the field *field-name*. (*x* can have fields, for example, when it corresponds to a structured data type.)

Methods

Array scalars have exactly the same methods as arrays. The default behavior of these methods is to internally convert the scalar to an equivalent 0-dimensional array and to call the corresponding array method. In addition, math operations on array scalars are defined so that the same hardware flags are set and used to interpret the results as for *ufunc*, so that the error state used for ufuncs also carries over to the math on array scalars.

The exceptions to the above rules are given below:

<code>generic.__array__</code>	<code>sc.__array__(dtype)</code> return 0-dim array from scalar with specified dtype
<code>generic.__array_wrap__</code>	<code>__array_wrap__</code> implementation for scalar types
<code>generic.squeeze([/, axis])</code>	Scalar method identical to <code>ndarray.squeeze</code> .
<code>generic.byteswap([/, inplace])</code>	Scalar method identical to <code>ndarray.byteswap</code> .
<code>generic.__reduce__</code>	Helper for pickle.
<code>generic.__setstate__</code>	
<code>generic.setflags(*[, write, align, uic])</code>	Scalar method identical to <code>ndarray.setflags</code> .

method

`generic.__array__()`
`sc.__array__(dtype)` return 0-dim array from scalar with specified dtype

method

`generic.squeeze(/, axis=None)`
 Scalar method identical to `ndarray.squeeze`.

method

`generic.byteswap(/, inplace=False)`
 Scalar method identical to `ndarray.byteswap`.

method

`generic.__reduce__()`
 Helper for pickle.

method

`generic.__setstate__()`

method

`generic.setflags(*, write=None, align=None, uic=None)`
 Scalar method identical to `ndarray.setflags`.

Utility method for typing:

<code>number.__class_getitem__(item, /)</code>	Return a parametrized wrapper around the <code>number</code> type.
--	--

method

`number.__class_getitem__(item, /)`

Return a parametrized wrapper around the `number` type.

New in version 1.22.

Returns

alias

[types.GenericAlias] A parametrized `number` type.

See also:

PEP 585

Type hinting generics in standard collections.

Examples

```
>>> from typing import Any
>>> import numpy as np
```

```
>>> np.signedinteger[Any]
numpy.signedinteger[typing.Any]
```

Defining new types

There are two ways to effectively define a new array scalar type (apart from composing structured types *dtypes* from the built-in scalar types): One way is to simply subclass the `ndarray` and overwrite the methods of interest. This will work to a degree, but internally certain behaviors are fixed by the data type of the array. To fully customize the data type of an array you need to define a new data-type, and register it with NumPy. Such new types can only be defined in C, using the *NumPy C-API*.

1.2.3 Data type objects (dtype)

A data type object (an instance of `numpy.dtype` class) describes how the bytes in the fixed-size block of memory corresponding to an array item should be interpreted. It describes the following aspects of the data:

1. Type of the data (integer, float, Python object, etc.)
2. Size of the data (how many bytes is in *e.g.* the integer)
3. Byte order of the data (little-endian or big-endian)
4. If the data type is structured data type, an aggregate of other data types, (*e.g.*, describing an array item consisting of an integer and a float),
 1. what are the names of the “fields” of the structure, by which they can be accessed,
 2. what is the data-type of each field, and
 3. which part of the memory block each field takes.
5. If the data type is a sub-array, what is its shape and data type.

To describe the type of scalar data, there are several *built-in scalar types* in NumPy for various precision of integers, floating-point numbers, *etc.* An item extracted from an array, *e.g.*, by indexing, will be a Python object whose type is the scalar type associated with the data type of the array.

Note that the scalar types are not *dtype* objects, even though they can be used in place of one whenever a data type specification is needed in NumPy.

Structured data types are formed by creating a data type whose field contain other data types. Each field has a name by which it can be accessed. The parent data type should be of sufficient size to contain all its fields; the parent is nearly always based on the *void* type which allows an arbitrary item size. Structured data types may also contain nested structured sub-array data types in their fields.

Finally, a data type can describe items that are themselves arrays of items of another data type. These sub-arrays must, however, be of a fixed size.

If an array is created using a data-type describing a sub-array, the dimensions of the sub-array are appended to the shape of the array when the array is created. Sub-arrays in a field of a structured type behave differently, see `arrays.indexing.fields`.

Sub-arrays always have a C-contiguous memory layout.

Example

A simple data type containing a 32-bit big-endian integer: (see *Specifying and constructing data types* for details on construction)

```
>>> import numpy as np
```

```
>>> dt = np.dtype('>i4')
>>> dt.byteorder
'>'
>>> dt.itemsize
4
>>> dt.name
'int32'
>>> dt.type is np.int32
True
```

The corresponding array scalar type is *int32*.

Example

A structured data type containing a 16-character string (in field 'name') and a sub-array of two 64-bit floating-point number (in field 'grades'):

```
>>> import numpy as np
```

```
>>> dt = np.dtype([('name', np.str_, 16), ('grades', np.float64, (2,))])
>>> dt['name']
dtype('<U16')
>>> dt['grades']
dtype('<f8', (2,))
```

Items of an array of this data type are wrapped in an *array scalar* type that also has two fields:

```
>>> import numpy as np
```

```
>>> x = np.array([('Sarah', (8.0, 7.0)), ('John', (6.0, 7.0))], dtype=dt)
>>> x[1]
('John', [6., 7.])
>>> x[1]['grades']
```

(continues on next page)

(continued from previous page)

```
array([6., 7.])
>>> type(x[1])
<class 'numpy.void'>
>>> type(x[1]['grades'])
<class 'numpy.ndarray'>
```

Specifying and constructing data types

Whenever a data-type is required in a NumPy function or method, either a *dtype* object or something that can be converted to one can be supplied. Such conversions are done by the *dtype* constructor:

```
dtype(dtype[, align, copy])
```

--

```
class numpy.dtype (dtype, align=False, copy=False, **kwargs)
```

–

```
dtype(dtype, align=False, copy=False, [metadata])
```

Create a data type object.

A numpy array is homogeneous, and contains elements described by a dtype object. A dtype object can be constructed from different combinations of fundamental numeric types.

Parameters

dtype

Object to be converted to a data type object.

align

[bool, optional] Add padding to the fields to match what a C compiler would output for a similar C-struct. Can be `True` only if *obj* is a dictionary or a comma-separated string. If a struct dtype is being created, this also sets a sticky alignment flag `isalignedstruct`.

copy

[bool, optional] Make a new copy of the data-type object. If `False`, the result may just be a reference to a built-in data-type object.

metadata

[dict, optional] An optional dictionary with dtype metadata.

Attributes

alignment

The required alignment (bytes) of this data-type according to the compiler.

base

Returns dtype for the base element of the subarrays, regardless of their dimension or shape.

byteorder

A character indicating the byte-order of this data-type object.

char

A unique character code for each of the 21 different built-in types.

descr

`__array_interface__` description of the data-type.

fields

Dictionary of named fields defined for this data type, or `None`.

flags

Bit-flags describing how this data type is to be interpreted.

hasobject

Boolean indicating whether this dtype contains any reference-counted objects in any fields or sub-dtypes.

isalignedstruct

Boolean indicating whether the dtype is a struct which maintains field alignment.

isbuiltin

Integer indicating how this dtype relates to the built-in dtypes.

isnative

Boolean indicating whether the byte order of this dtype is native to the platform.

itemsize

The element size of this data-type object.

kind

A character code (one of 'biufcmMOSTUV') identifying the general kind of data.

metadata

Either `None` or a readonly dictionary of metadata (mappingproxy).

name

A bit-width name for this data-type.

names

Ordered list of field names, or `None` if there are no fields.

ndim

Number of dimensions of the sub-array if this data type describes a sub-array, and 0 otherwise.

num

A unique number for each of the 21 different built-in types.

shape

Shape tuple of the sub-array if this data type describes a sub-array, and `()` otherwise.

str

The array-protocol typestring of this data-type object.

subdtype

Tuple (`item_dtype`, `shape`) if this *dtype* describes a sub-array, and `None` otherwise.

type

Methods

<code>newbyteorder([new_order])</code>	Return a new dtype with a different byte order.
--	---

method

`dtype.newbyteorder(new_order='S', /)`

Return a new dtype with a different byte order.

Changes are also made in all fields and sub-arrays of the data type.

Parameters

new_order

[string, optional] Byte order to force; a value from the byte order specifications below. The default value ('S') results in swapping the current byte order. *new_order* codes can be any of:

- 'S' - swap dtype from current to opposite endian
- {'<', 'little'} - little endian
- {'>', 'big'} - big endian
- {'=' , 'native'} - native order
- {'|', 'T'} - ignore (no change to byte order)

Returns

new_dtype

[dtype] New dtype object with the given change to the byte order.

Notes

Changes are also made in all fields and sub-arrays of the data type.

Examples

```
>>> import sys
>>> sys_is_le = sys.byteorder == 'little'
>>> native_code = '<' if sys_is_le else '>'
>>> swapped_code = '>' if sys_is_le else '<'
>>> import numpy as np
>>> native_dt = np.dtype(native_code+'i2')
>>> swapped_dt = np.dtype(swapped_code+'i2')
>>> native_dt.newbyteorder('S') == swapped_dt
True
>>> native_dt.newbyteorder() == swapped_dt
True
>>> native_dt == swapped_dt.newbyteorder('S')
True
>>> native_dt == swapped_dt.newbyteorder('=')
True
>>> native_dt == swapped_dt.newbyteorder('N')
True
>>> native_dt == native_dt.newbyteorder('|')
True
```

(continues on next page)

(continued from previous page)

```
>>> np.dtype('<i2') == native_dt.newbyteorder('<')
True
>>> np.dtype('<i2') == native_dt.newbyteorder('L')
True
>>> np.dtype('>i2') == native_dt.newbyteorder('>')
True
>>> np.dtype('>i2') == native_dt.newbyteorder('B')
True
```

See also:

result_type

Examples

Using array-scalar type:

```
>>> import numpy as np
>>> np.dtype(np.int16)
dtype('int16')
```

Structured type, one field name 'f1', containing int16:

```
>>> np.dtype([('f1', np.int16)])
dtype([('f1', '<i2')])
```

Structured type, one field named 'f1', in itself containing a structured type with one field:

```
>>> np.dtype([('f1', [('f1', np.int16)])])
dtype([('f1', [('f1', '<i2')])])
```

Structured type, two fields: the first field contains an unsigned int, the second an int32:

```
>>> np.dtype([('f1', np.uint64), ('f2', np.int32)])
dtype([('f1', '<u8'), ('f2', '<i4')])
```

Using array-protocol type strings:

```
>>> np.dtype([('a', 'f8'), ('b', 'S10')])
dtype([('a', '<f8'), ('b', 'S10')])
```

Using comma-separated field formats. The shape is (2,3):

```
>>> np.dtype("i4, (2,3)f8")
dtype([('f0', '<i4'), ('f1', '<f8', (2, 3))])
```

Using tuples. int is a fixed type, 3 the field's shape. void is a flexible type, here of size 10:

```
>>> np.dtype([('hello', (np.int64, 3)), ('world', np.void, 10)])
dtype([('hello', '<i8', (3,)), ('world', 'V10')])
```

Subdivide int16 into 2 int8's, called x and y. 0 and 1 are the offsets in bytes:

```
>>> np.dtype((np.int16, {'x': (np.int8, 0), 'y': (np.int8, 1)}))
dtype((numpy.int16, [('x', 'i1'), ('y', 'i1')]))
```

Using dictionaries. Two fields named 'gender' and 'age':

```
>>> np.dtype({'names': ['gender', 'age'], 'formats': ['S1', np.uint8]})
dtype([('gender', 'S1'), ('age', 'u1')])
```

Offsets in bytes, here 0 and 25:

```
>>> np.dtype({'surname': ('S25', 0), 'age': (np.uint8, 25)})
dtype([('surname', 'S25'), ('age', 'u1')])
```

What can be converted to a data-type object is described below:

***dtype* object**

Used as-is.

None

The default data type: *float64*.

Array-scalar types

The 24 built-in *array scalar type objects* all convert to an associated data-type object. This is true for their subclasses as well.

Note that not all data-type information can be supplied with a type-object: for example, *flexible* data-types have a default *itemsize* of 0, and require an explicitly given size to be useful.

Example

```
>>> import numpy as np
```

```
>>> dt = np.dtype(np.int32)      # 32-bit integer
>>> dt = np.dtype(np.complex128) # 128-bit complex floating-point number
```

Generic types

The generic hierarchical type objects convert to corresponding type objects according to the associations:

<i>number, inexact, floating</i>	<i>float64</i>
<i>complexfloating</i>	<i>complex128</i>
<i>integer, signedinteger</i>	<i>int_</i>
<i>unsignedinteger</i>	<i>uint</i>
<i>generic, flexible</i>	<i>void</i>

Deprecated since version 1.19: This conversion of generic scalar types is deprecated. This is because it can be unexpected in a context such as `arr.astype(dtype=np.floating)`, which casts an array of `float32` to an array of `float64`, even though `float32` is a subtype of `np.floating`.

Built-in Python types

Several Python types are equivalent to a corresponding array scalar when used to generate a *dtype* object:

Python type	NumPy type
<code>int</code>	<code>int_</code>
<code>bool</code>	<code>bool_</code>
<code>float</code>	<code>float64</code>
<code>complex</code>	<code>complex128</code>
<code>bytes</code>	<code>bytes_</code>
<code>str</code>	<code>str_</code>
<code>memoryview</code>	<code>void</code>
(all others)	<code>object_</code>

Note that `str_` corresponds to UCS4 encoded unicode strings.

Example

```
>>> import numpy as np
```

```
>>> dt = np.dtype(float)    # Python-compatible floating-point number
>>> dt = np.dtype(int)     # Python-compatible integer
>>> dt = np.dtype(object)   # Python object
```

Note: All other types map to `object_` for convenience. Code should expect that such types may map to a specific (new) dtype in the future.

Types with `.dtype`

Any type object with a `dtype` attribute: The attribute will be accessed and used directly. The attribute must return something that is convertible into a dtype object.

Several kinds of strings can be converted. Recognized strings can be prepended with `'>'` (big-endian), `'<'` (little-endian), or `'='` (hardware-native, the default), to specify the byte order.

One-character strings

Each built-in data-type has a character code (the updated Numeric typecodes), that uniquely identifies it.

Example

```
>>> import numpy as np
```

```
>>> dt = np.dtype('b')    # byte, native byte order
>>> dt = np.dtype('>H')   # big-endian unsigned short
>>> dt = np.dtype('<f')   # little-endian single-precision float
>>> dt = np.dtype('d')    # double-precision floating-point number
```

Array-protocol type strings (see [The array interface protocol](#))

The first character specifies the kind of data and the remaining characters specify the number of bytes per item, except for Unicode, where it is interpreted as the number of characters, and except `b1` which represents boolean. The item size must correspond to an existing type, or an error will be raised. The supported kinds are

' ? '	boolean
' b '	(signed) byte
' B '	unsigned byte
' h '	(signed) short
' H '	unsigned short
' i '	(signed) integer
' I '	unsigned integer
' l '	(signed) long integer
' L '	unsigned long integer
' q '	(signed) long long integer
' Q '	unsigned long long integer
' f '	single precision
' F '	complex single precision
' d '	double precision
' D '	complex double precision
' g '	long precision
' G '	complex long double precision
' O '	(Python) objects
' S '	zero-terminated bytes (not recommended)
' U '	Unicode string
' V '	raw data (<i>void</i>)

Example

```
>>> import numpy as np
```

```
>>> dt = np.dtype('i4')      # 32-bit signed integer
>>> dt = np.dtype('f8')      # 64-bit floating-point number
>>> dt = np.dtype('c16')     # 128-bit complex floating-point number
>>> dt = np.dtype('S25')     # 25-length zero-terminated bytes
>>> dt = np.dtype('U25')     # 25-character string
```

String with comma-separated fields

A short-hand notation for specifying the format of a structured data type is a comma-separated string of basic formats.

A basic format in this context is an optional shape specifier followed by an array-protocol type string. Parenthesis are required on the shape if it has more than one dimension. NumPy allows a modification on the format in that any string that can uniquely identify the type can be used to specify the data-type in a field. The generated data-type fields are named 'f0', 'f1', ..., 'f<N-1>' where N (>1) is the number of comma-separated basic formats in the string. If the optional shape specifier is provided, then the data-type for the corresponding field describes a sub-array.

Example

- field named f0 containing a 32-bit integer
- field named f1 containing a 2 x 3 sub-array of 64-bit floating-point numbers
- field named f2 containing a 32-bit floating-point number

```
>>> import numpy as np
>>> dt = np.dtype("i4, (2,3)f8, f4")
```

- field named f0 containing a 3-character string
- field named f1 containing a sub-array of shape (3,) containing 64-bit unsigned integers
- field named f2 containing a 3 x 4 sub-array containing 10-character strings

```
>>> import numpy as np
>>> dt = np.dtype("S3, 3u8, (3,4)S10")
```

Type strings

Any string name of a NumPy dtype, e.g.:

Example

```
>>> import numpy as np
```

```
>>> dt = np.dtype('uint32') # 32-bit unsigned integer
>>> dt = np.dtype('float64') # 64-bit floating-point number
```

(flexible_dtype, itemsize)

The first argument must be an object that is converted to a zero-sized flexible data-type object, the second argument is an integer providing the desired itemsize.

Example

```
>>> import numpy as np
```

```
>>> dt = np.dtype((np.void, 10)) # 10-byte wide data block
>>> dt = np.dtype(('U', 10)) # 10-character unicode string
```

(fixed_dtype, shape)

The first argument is any object that can be converted into a fixed-size data-type object. The second argument is the desired shape of this type. If the shape parameter is 1, then the data-type object used to be equivalent to fixed dtype. This behaviour is deprecated since NumPy 1.17 and will raise an error in the future. If *shape* is a tuple, then the new dtype defines a sub-array of the given shape.

Example

```
>>> import numpy as np
```

```
>>> dt = np.dtype((np.int32, (2,2))) # 2 x 2 integer sub-array
>>> dt = np.dtype(('i4, (2,3)f8, f4', (2,3))) # 2 x 3 structured sub-array
```

[(field_name, field_dtype, field_shape), ...]

obj should be a list of fields where each field is described by a tuple of length 2 or 3. (Equivalent to the `descr` item in the `__array_interface__` attribute.)

The first element, *field_name*, is the field name (if this is ' ' then a standard field name, 'f#', is assigned). The field name may also be a 2-tuple of strings where the first string is either a “title” (which may be any string or unicode string) or meta-data for the field which can be any object, and the second string is the “name” which must be a valid Python identifier.

The second element, *field_dtype*, can be anything that can be interpreted as a data-type.

The optional third element *field_shape* contains the shape if this field represents an array of the data-type in the second element. Note that a 3-tuple with a third argument equal to 1 is equivalent to a 2-tuple.

This style does not accept *align* in the *dtype* constructor as it is assumed that all of the memory is accounted for by the array interface description.

Example

Data-type with fields `big` (big-endian 32-bit integer) and `little` (little-endian 32-bit integer):

```
>>> import numpy as np
```

```
>>> dt = np.dtype([('big', '>i4'), ('little', '<i4')])
```

Data-type with fields `R`, `G`, `B`, `A`, each being an unsigned 8-bit integer:

```
>>> dt = np.dtype([('R', 'u1'), ('G', 'u1'), ('B', 'u1'), ('A', 'u1')])
```

```
{'names': ..., 'formats': ..., 'offsets': ..., 'titles': ..., 'itemsize': ...}
```

This style has two required and three optional keys. The *names* and *formats* keys are required. Their respective values are equal-length lists with the field names and the field formats. The field names must be strings and the field formats can be any object accepted by *dtype* constructor.

When the optional keys *offsets* and *titles* are provided, their values must each be lists of the same length as the *names* and *formats* lists. The *offsets* value is a list of byte offsets (limited to `ctypes.c_int`) for each field, while the *titles* value is a list of titles for each field (`None` can be used if no title is desired for that field). The *titles* can be any object, but when a `str` object will add another entry to the fields dictionary keyed by the title and referencing the same field tuple which will contain the title as an additional tuple member.

The *itemsize* key allows the total size of the dtype to be set, and must be an integer large enough so all the fields are within the dtype. If the dtype being constructed is aligned, the *itemsize* must also be divisible by the struct alignment. Total dtype *itemsize* is limited to `ctypes.c_int`.

Example

Data type with fields `r`, `g`, `b`, `a`, each being an 8-bit unsigned integer:

```
>>> import numpy as np
```

```
>>> dt = np.dtype({'names': ['r', 'g', 'b', 'a'],  
...                 'formats': [np.uint8, np.uint8, np.uint8, np.uint8]})
```

Data type with fields `r` and `b` (with the given titles), both being 8-bit unsigned integers, the first at byte position 0 from the start of the field and the second at position 2:

```
>>> dt = np.dtype({'names': ['r', 'b'], 'formats': ['u1', 'u1'],  
...               'offsets': [0, 2],  
...               'titles': ['Red pixel', 'Blue pixel']})
```

```
{'field1': ..., 'field2': ..., ...}
```

This usage is discouraged, because it is ambiguous with the other dict-based construction method. If you have a field called 'names' and a field called 'formats' there will be a conflict.

This style allows passing in the *fields* attribute of a data-type object.

obj should contain string or unicode keys that refer to (data-type, offset) or (data-type, offset, title) tuples.

Example

Data type containing field `col1` (10-character string at byte position 0), `col2` (32-bit float at byte position 10), and `col3` (integers at byte position 14):

```
>>> import numpy as np
```

```
>>> dt = np.dtype({'col1': ('U10', 0), 'col2': (np.float32, 10),
...               'col3': (int, 14)})
```

(base_dtype, new_dtype)

In NumPy 1.7 and later, this form allows *base_dtype* to be interpreted as a structured dtype. Arrays created with this dtype will have underlying dtype *base_dtype* but will have fields and flags taken from *new_dtype*. This is useful for creating custom structured dtypes, as done in *record arrays*.

This form also makes it possible to specify struct dtypes with overlapping fields, functioning like the 'union' type in C. This usage is discouraged, however, and the union mechanism is preferred.

Both arguments must be convertible to data-type objects with the same total size.

Example

32-bit integer, whose first two bytes are interpreted as an integer via field `real`, and the following two bytes via field `imag`.

```
>>> import numpy as np
```

```
>>> dt = np.dtype((np.int32, {'real': (np.int16, 0), 'imag': (np.int16, 2)}))
```

32-bit integer, which is interpreted as consisting of a sub-array of shape `(4,)` containing 8-bit integers:

```
>>> dt = np.dtype((np.int32, (np.int8, 4)))
```

32-bit integer, containing fields `r`, `g`, `b`, `a` that interpret the 4 bytes in the integer as four unsigned integers:

```
>>> dt = np.dtype(('i4', [(('r', 'u1'), ('g', 'u1'), ('b', 'u1'), ('a', 'u1'))]))
```

Checking the data type

When checking for a specific data type, use `==` comparison.

Example

```
>>> import numpy as np

>>> a = np.array([1, 2], dtype=np.float32)
>>> a.dtype == np.float32
True
```

As opposed to Python types, a comparison using `is` should not be used.

First, NumPy treats data type specifications (everything that can be passed to the `dtype` constructor) as equivalent to the data type object itself. This equivalence can only be handled through `==`, not through `is`.

Example

A `dtype` object is equal to all data type specifications that are equivalent to it.

```
>>> import numpy as np

>>> a = np.array([1, 2], dtype=np.float64)
>>> a.dtype == np.dtype(np.float64)
True
>>> a.dtype == np.float64
True
>>> a.dtype == float
True
>>> a.dtype == "float64"
True
>>> a.dtype == "d"
True
```

Second, there is no guarantee that data type objects are singletons.

Example

Do not use `is` because data type objects may or may not be singletons.

```
>>> import numpy as np

>>> np.dtype(float) is np.dtype(float)
True
>>> np.dtype([('a', float)]) is np.dtype([('a', float)])
False
```

dtype

NumPy data type descriptions are instances of the `dtype` class.

Attributes

The type of the data is described by the following `dtype` attributes:

<code>dtype.type</code>	
<code>dtype.kind</code>	A character code (one of 'biufcmMOSTUV') identifying the general kind of data.
<code>dtype.char</code>	A unique character code for each of the 21 different built-in types.
<code>dtype.num</code>	A unique number for each of the 21 different built-in types.
<code>dtype.str</code>	The array-protocol typestring of this data-type object.

attribute

`dtype.type = None`

attribute

`dtype.kind`

A character code (one of 'biufcmMOSTUV') identifying the general kind of data.

b	boolean
i	signed integer
u	unsigned integer
f	floating-point
c	complex floating-point
m	timedelta
M	datetime
O	object
S	(byte-)string
T	string (StringDType)
U	Unicode
V	void

Examples

```

>>> import numpy as np
>>> dt = np.dtype(np.int32)
>>> dt.kind
'i'
>>> dt = np.dtype(np.float64)
>>> dt.kind
'f'
>>> dt = np.dtype([('field1', np.float64)])
>>> dt.kind
'V'

```

attribute

`dtype.char`

A unique character code for each of the 21 different built-in types.

Examples

```
>>> import numpy as np
>>> x = np.dtype(float)
>>> x.char
'd'
```

attribute

`dtype.num`

A unique number for each of the 21 different built-in types.

These are roughly ordered from least-to-most precision.

Examples

```
>>> import numpy as np
>>> dt = np.dtype(str)
>>> dt.num
19
```

```
>>> dt = np.dtype(float)
>>> dt.num
12
```

attribute

`dtype.str`

The array-protocol typestring of this data-type object.

Size of the data is in turn described by:

<code>dtype.name</code>	A bit-width name for this data-type.
<code>dtype.itemsize</code>	The element size of this data-type object.

attribute

`dtype.name`

A bit-width name for this data-type.

Un-sized flexible data-type objects do not have this attribute.

Examples

```
>>> import numpy as np
>>> x = np.dtype(float)
>>> x.name
'float64'
>>> x = np.dtype([('a', np.int32, 8), ('b', np.float64, 6)])
>>> x.name
'void640'
```

attribute

`dtype.itemsize`

The element size of this data-type object.

For 18 of the 21 types this number is fixed by the data-type. For the flexible data-types, this number can be anything.

Examples

```
>>> import numpy as np
>>> arr = np.array([[1, 2], [3, 4]])
>>> arr.dtype
dtype('int64')
>>> arr.itemsize
8
```

```
>>> dt = np.dtype([('name', np.str_, 16), ('grades', np.float64, (2,))])
>>> dt.itemsize
80
```

Endianness of this data:

`dtype.byteorder`

A character indicating the byte-order of this data-type object.

attribute

`dtype.byteorder`

A character indicating the byte-order of this data-type object.

One of:

'='	native
'<'	little-endian
'>'	big-endian
' '	not applicable

All built-in data-type objects have byteorder either '=' or '|'.

Examples

```
>>> import numpy as np
>>> dt = np.dtype(np.int16)
>>> dt.byteorder
'='
>>> # endian is not relevant for 8 bit numbers
>>> np.dtype(np.int8).byteorder
'|'
>>> # or ASCII strings
>>> np.dtype('S2').byteorder
'|'
>>> # Even if specific code is given, and it is native
>>> # '=' is the byteorder
>>> import sys
>>> sys_is_le = sys.byteorder == 'little'
>>> native_code = '<' if sys_is_le else '>'
>>> swapped_code = '>' if sys_is_le else '<'
>>> dt = np.dtype(native_code + 'i2')
>>> dt.byteorder
'='
>>> # Swapped code shows up as itself
>>> dt = np.dtype(swapped_code + 'i2')
>>> dt.byteorder == swapped_code
True
```

Information about sub-data-types in a structured data type:

<code>dtype.fields</code>	Dictionary of named fields defined for this data type, or None.
<code>dtype.names</code>	Ordered list of field names, or None if there are no fields.

attribute

`dtype.fields`

Dictionary of named fields defined for this data type, or None.

The dictionary is indexed by keys that are the names of the fields. Each entry in the dictionary is a tuple fully describing the field:

```
(dtype, offset[, title])
```

Offset is limited to C int, which is signed and usually 32 bits. If present, the optional title can be any object (if it is a string or unicode then it will also be a key in the fields dictionary, otherwise it's meta-data). Notice also that the first two elements of the tuple can be passed directly as arguments to the `ndarray.getfield` and `ndarray.setfield` methods.

See also:

`ndarray.getfield`, `ndarray.setfield`

Examples

```
>>> import numpy as np
>>> dt = np.dtype([('name', np.str_, 16), ('grades', np.float64, (2,))])
>>> print(dt.fields)
{'name': (dtype('<U16'), 0), 'grades': (dtype('<f8', (2,)), 64)}
```

attribute

`dtype.names`

Ordered list of field names, or None if there are no fields.

The names are ordered according to increasing byte offset. This can be used, for example, to walk through all of the named fields in offset order.

Examples

```
>>> dt = np.dtype([('name', np.str_, 16), ('grades', np.float64, (2,))])
>>> dt.names
('name', 'grades')
```

For data types that describe sub-arrays:

<code>dtype.subdtype</code>	Tuple (<code>item_dtype</code> , <code>shape</code>) if this <code>dtype</code> describes a sub-array, and None otherwise.
<code>dtype.shape</code>	Shape tuple of the sub-array if this data type describes a sub-array, and () otherwise.

attribute

`dtype.subdtype`

Tuple (`item_dtype`, `shape`) if this `dtype` describes a sub-array, and None otherwise.

The *shape* is the fixed shape of the sub-array described by this data type, and *item_dtype* the data type of the array.

If a field whose dtype object has this attribute is retrieved, then the extra dimensions implied by *shape* are tacked on to the end of the retrieved array.

See also:

`dtype.base`

Examples

```
>>> import numpy as np
>>> x = np.dtype('8f')
>>> x.subdtype
(dtype('float32'), (8,))
```

```
>>> x = np.dtype(np.int16)
>>> x.subdtype
>>>
```

attribute

dtype.shape

Shape tuple of the sub-array if this data type describes a sub-array, and `()` otherwise.

Examples

```
>>> import numpy as np
>>> dt = np.dtype('i4', 4)
>>> dt.shape
(4,)
```

```
>>> dt = np.dtype('i4', (2, 3))
>>> dt.shape
(2, 3)
```

Attributes providing additional information:

<code>dtype.hasobject</code>	Boolean indicating whether this dtype contains any reference-counted objects in any fields or sub-dtypes.
<code>dtype.flags</code>	Bit-flags describing how this data type is to be interpreted.
<code>dtype.isbuiltin</code>	Integer indicating how this dtype relates to the built-in dtypes.
<code>dtype.isnative</code>	Boolean indicating whether the byte order of this dtype is native to the platform.
<code>dtype.descr</code>	<code>__array_interface__</code> description of the data-type.
<code>dtype.alignment</code>	The required alignment (bytes) of this data-type according to the compiler.
<code>dtype.base</code>	Returns dtype for the base element of the subarrays, regardless of their dimension or shape.

attribute**dtype.hasobject**

Boolean indicating whether this dtype contains any reference-counted objects in any fields or sub-dtypes.

Recall that what is actually in the ndarray memory representing the Python object is the memory address of that object (a pointer). Special handling may be required, and this attribute is useful for distinguishing data types that may contain arbitrary Python objects and data-types that won't.

attribute**dtype.flags**

Bit-flags describing how this data type is to be interpreted.

Bit-masks are in `numpy._core.multiarray` as the constants `ITEM_HASOBJECT`, `LIST_PICKLE`, `ITEM_IS_POINTER`, `NEEDS_INIT`, `NEEDS_PYAPI`, `USE_GETITEM`, `USE_SETITEM`. A full explanation of these flags is in C-API documentation; they are largely useful for user-defined data-types.

The following example demonstrates that operations on this particular dtype requires Python C-API.

Examples

```
>>> import numpy as np
>>> x = np.dtype([('a', np.int32, 8), ('b', np.float64, 6)])
>>> x.flags
16
>>> np._core.multiarray.NEEDS_PYAPI
16
```

attribute

`dtype.isbuiltin`

Integer indicating how this dtype relates to the built-in dtypes.

Read-only.

0	if this is a structured array type, with fields
1	if this is a dtype compiled into numpy (such as ints, floats etc)
2	if the dtype is for a user-defined numpy type A user-defined type uses the numpy C-API machinery to extend numpy to handle a new array type. See <code>user.user-defined-data-types</code> in the NumPy manual.

Examples

```
>>> import numpy as np
>>> dt = np.dtype(np.int16)
>>> dt.isbuiltin
1
>>> dt = np.dtype(np.float64)
>>> dt.isbuiltin
1
>>> dt = np.dtype([('field1', np.float64)])
>>> dt.isbuiltin
0
```

attribute

`dtype.isnative`

Boolean indicating whether the byte order of this dtype is native to the platform.

attribute

`dtype.descr`

`__array_interface__` description of the data-type.

The format is that required by the 'descr' key in the `__array_interface__` attribute.

Warning: This attribute exists specifically for `__array_interface__`, and passing it directly to `numpy.dtype` will not accurately reconstruct some dtypes (e.g., scalar and subarray dtypes).

Examples

```
>>> import numpy as np
>>> x = np.dtype(float)
>>> x.descr
[('', '<f8')]
```

```
>>> dt = np.dtype([('name', np.str_, 16), ('grades', np.float64, (2,))])
>>> dt.descr
[('name', '<U16'), ('grades', '<f8', (2,))]
```

attribute

`dtype.alignment`

The required alignment (bytes) of this data-type according to the compiler.

More information is available in the C-API section of the manual.

Examples

```
>>> import numpy as np
>>> x = np.dtype(np.int32)
>>> x.alignment
4
```

```
>>> x = np.dtype(np.float64)
>>> x.alignment
8
```

attribute

`dtype.base`

Returns dtype for the base element of the subarrays, regardless of their dimension or shape.

See also:

`dtype.subdtype`

Examples

```
>>> import numpy as np
>>> x = np.dtype('8f')
>>> x.base
dtype('float32')
```

```
>>> x = np.dtype(np.int16)
>>> x.base
dtype('int16')
```

Metadata attached by the user:

`dtype.metadata`

Either None or a readonly dictionary of metadata (mappingproxy).

attribute

`dtype.metadata`

Either None or a readonly dictionary of metadata (mappingproxy).

The metadata field can be set using any dictionary at data-type creation. NumPy currently has no uniform approach to propagating metadata; although some array operations preserve it, there is no guarantee that others will.

Warning: Although used in certain projects, this feature was long undocumented and is not well supported. Some aspects of metadata propagation are expected to change in the future.

Examples

```
>>> import numpy as np
>>> dt = np.dtype(float, metadata={"key": "value"})
>>> dt.metadata["key"]
'value'
>>> arr = np.array([1, 2, 3], dtype=dt)
>>> arr.dtype.metadata
mappingproxy({'key': 'value'})
```

Adding arrays with identical datatypes currently preserves the metadata:

```
>>> (arr + arr).dtype.metadata
mappingproxy({'key': 'value'})
```

If the arrays have different dtype metadata, the first one wins:

```
>>> dt2 = np.dtype(float, metadata={"key2": "value2"})
>>> arr2 = np.array([3, 2, 1], dtype=dt2)
>>> print((arr + arr2).dtype.metadata)
{'key': 'value'}
```

Methods

Data types have the following method for changing the byte order:

<code>dtype.newbyteorder([new_order])</code>	Return a new dtype with a different byte order.
--	---

The following methods implement the pickle protocol:

<code>dtype.__reduce__</code>	Helper for pickle.
<code>dtype.__setstate__</code>	

method

`dtype.__reduce__()`

Helper for pickle.

method

`dtype.__setstate__()`

Utility method for typing:

<code>dtype.__class_getitem__(item, /)</code>	Return a parametrized wrapper around the <code>dtype</code> type.
---	---

method

`dtype.__class_getitem__(item, /)`

Return a parametrized wrapper around the `dtype` type.

New in version 1.22.

Returns

alias

[types.GenericAlias] A parametrized `dtype` type.

See also:

PEP 585

Type hinting generics in standard collections.

Examples

```
>>> import numpy as np
```

```
>>> np.dtype[np.int64]  
numpy.dtype[numpy.int64]
```

Comparison operations:

<code>dtype.__ge__(value, /)</code>	Return self>=value.
<code>dtype.__gt__(value, /)</code>	Return self>value.
<code>dtype.__le__(value, /)</code>	Return self<=value.
<code>dtype.__lt__(value, /)</code>	Return self<value.

method

`dtype.__ge__(value, /)`

Return self>=value.

method

`dtype.__gt__(value, /)`

Return self>value.

method

`dtype.__le__(value, /)`

Return self<=value.

method

`dtype.__lt__(value, /)`

Return self<value.

1.2.4 Data type promotion in NumPy

When mixing two different data types, NumPy has to determine the appropriate dtype for the result of the operation. This step is referred to as *promotion* or *finding the common dtype*.

In typical cases, the user does not need to worry about the details of promotion, since the promotion step usually ensures that the result will either match or exceed the precision of the input.

For example, when the inputs are of the same dtype, the dtype of the result matches the dtype of the inputs:

```
>>> np.int8(1) + np.int8(1)
np.int8(2)
```

Mixing two different dtypes normally produces a result with the dtype of the higher precision input:

```
>>> np.int8(4) + np.int64(8)   # 64 > 8
np.int64(12)
>>> np.float32(3) + np.float16(3)   # 32 > 16
np.float32(6.0)
```

In typical cases, this does not lead to surprises. However, if you work with non-default dtypes like unsigned integers and low-precision floats, or if you mix NumPy integers, NumPy floats, and Python scalars, some details of NumPy promotion rules may be relevant. Note that these detailed rules do not always match those of other languages¹.

Numerical dtypes come in four “kinds” with a natural hierarchy.

1. unsigned integers (`uint`)
2. signed integers (`int`)
3. float (`float`)
4. complex (`complex`)

In addition to kind, NumPy numerical dtypes also have an associated precision, specified in bits. Together, the kind and precision specify the dtype. For example, a `uint8` is an unsigned integer stored using 8 bits.

The result of an operation will always be of an equal or higher kind of any of the inputs. Furthermore, the result will always have a precision greater than or equal to those of the inputs. Already, this can lead to some examples which may be unexpected:

1. When mixing floating point numbers and integers, the precision of the integer may force the result to a higher precision floating point. For example, the result of an operation involving `int64` and `float16` is `float64`.
2. When mixing unsigned and signed integers with the same precision, the result will have *higher* precision than either inputs. Additionally, if one of them has 64bit precision already, no higher precision integer is available and for example an operation involving `int64` and `uint64` gives `float64`.

Please see the *Numerical promotion* section and image below for details on both.

¹ To a large degree, this may just be for choices made early on in NumPy’s predecessors. For more details, see [NEP 50](#).

Detailed behavior of Python scalars

Since NumPy 2.0², an important point in our promotion rules is that although operations involving two NumPy dtypes never lose precision, operations involving a NumPy dtype and a Python scalar (`int`, `float`, or `complex`) *can* lose precision. For instance, it is probably intuitive that the result of an operation between a Python integer and a NumPy integer should be a NumPy integer. However, Python integers have arbitrary precision whereas all NumPy dtypes have fixed precision, so the arbitrary precision of Python integers cannot be preserved.

More generally, NumPy considers the “kind” of Python scalars, but ignores their precision when determining the result dtype. This is often convenient. For instance, when working with arrays of a low precision dtype, it is usually desirable for simple operations with Python scalars to preserve the dtype.

```
>>> arr_float32 = np.array([1, 2.5, 2.1], dtype=np.float32)
>>> arr_float32 + 10.0 # undesirable to promote to float64
array([11. , 12.5, 12.1], dtype=float32)
>>> arr_int16 = np.array([3, 5, 7], dtype=np.int16)
>>> arr_int16 + 10 # undesirable to promote to int64
array([13, 15, 17], dtype=int16)
```

In both cases, the result precision is dictated by the NumPy dtype. Because of this, `arr_float32 + 3.0` behaves the same as `arr_float32 + np.float32(3.0)`, and `arr_int16 + 10` behaves as `arr_int16 + np.int16(10.)`.

As another example, when mixing NumPy integers with a Python float or complex, the result always has type `float64` or `complex128`:

```
>> np.int16(1) + 1.0 np.float64(2.0)
```

However, these rules can also lead to surprising behavior when working with low precision dtypes.

First, since the Python value is converted to a NumPy one before the operation can be performed, operations can fail with an error when the result seems obvious. For instance, `np.int8(1) + 1000` cannot continue because 1000 exceeds the maximum value of an `int8`. When the Python scalar cannot be coerced to the NumPy dtype, an error is raised:

```
>>> np.int8(1) + 1000
Traceback (most recent call last):
...
OverflowError: Python integer 1000 out of bounds for int8
>>> np.int64(1) * 10**100
Traceback (most recent call last):
...
OverflowError: Python int too large to convert to C long
>>> np.float32(1) + 1e300
np.float32(inf)
... RuntimeWarning: overflow encountered in cast
```

Second, since the Python float or integer precision is always ignored, a low precision NumPy scalar will keep using its lower precision unless explicitly converted to a higher precision NumPy dtype or Python scalar (e.g. via `int()`, `float()`, or `scalar.item()`). This lower precision may be detrimental to some calculations or lead to incorrect results, especially in the case of integer overflows:

```
>>> np.int8(100) + 100 # the result exceeds the capacity of int8
np.int8(-56)
... RuntimeWarning: overflow encountered in scalar add
```

² See also [NEP 50](#) which changed the rules for NumPy 2.0. Previous versions of NumPy would sometimes return higher precision results based on the input value of Python scalars. Further, previous versions of NumPy would typically ignore the higher precision of NumPy scalars or 0-D arrays for promotion purposes.

Note that NumPy warns when overflows occur for scalars, but not for arrays; e.g., `np.array(100, dtype=np.uint8) + 100` will *not* warn.

Numerical promotion

The following image shows the numerical promotion rules with the kinds on the vertical axis and the precision on the horizontal axis.

The input dtype with the higher kind determines the kind of the result dtype. The result dtype has a precision as low as possible without appearing to the left of either input dtype in the diagram.

Note the following specific rules and observations:

1. When a Python float or complex interacts with a NumPy integer the result will be float64 or complex128 (yellow border). NumPy booleans will also be cast to the default integer³. This is not relevant when additionally NumPy floating point values are involved.
2. The precision is drawn such that `float16 < int16 < uint16` because large uint16 do not fit int16 and large int16 will lose precision when stored in a float16. This pattern however is broken since NumPy always considers float64 and complex128 to be acceptable promotion results for any integer value.
3. A special case is that NumPy promotes many combinations of signed and unsigned integers to float64. A higher kind is used here because no signed integer dtype is sufficiently precise to hold a uint64.

Exceptions to the general promotion rules

In NumPy promotion refers to what specific functions do with the result and in some cases, this means that NumPy may deviate from what the `np.result_type` would give.

³ The default integer is marked as `int64` in the schema but is `int32` on 32bit platforms. However, most modern systems are 64bit.

Behavior of `sum` and `prod`

`np.sum` and `np.prod` will always return the default integer type when summing over integer values (or booleans). This is usually an `int64`. The reason for this is that integer summations are otherwise very likely to overflow and give confusing results. This rule also applies to the underlying `np.add.reduce` and `np.multiply.reduce`.

Notable behavior with NumPy or Python integer scalars

NumPy promotion refers to the result dtype and operation precision, but the operation will sometimes dictate that result. Division always returns floating point values and comparison always booleans.

This leads to what may appear as “exceptions” to the rules:

- NumPy comparisons with Python integers or mixed precision integers always return the correct result. The inputs will never be cast in a way which loses precision.
- Equality comparisons between types which cannot be promoted will be considered all `False` (equality) or all `True` (not-equal).
- Unary math functions like `np.sin` that always return floating point values, accept any Python integer input by converting it to `float64`.
- Division always returns floating point values and thus also allows divisions between any NumPy integer with any Python integer value by casting both to `float64`.

In principle, some of these exceptions may make sense for other functions. Please raise an issue if you feel this is the case.

Notable behavior with Python builtin type classes

When combining Python’s builtin scalar *types* (i.e., `float`, `int`, or `complex`, not scalar *values*), the promotion rules can appear surprising:

```
>>> np.result_type(7, np.array([1], np.float32))
dtype('float32') # The scalar value '7' does not impact type promotion
>>> np.result_type(type(7), np.array([1], np.float32))
dtype('float64') # The *type* of the scalar value '7' does impact promotion
# Similar situations happen with Python's float and complex types
```

The reason for this behavior is that NumPy converts `int` to its default integer type, and uses that type for promotion:

```
>>> np.result_type(int)
dtype('int64')
```

See also *Built-in Python types* for more details.

Promotion of non-numerical datatypes

NumPy extends the promotion to non-numerical types, although in many cases promotion is not well defined and simply rejected.

The following rules apply:

- NumPy byte strings (`np.bytes_`) can be promoted to unicode strings (`np.str_`). However, casting the bytes to unicode will fail for non-ascii characters.
- For some purposes NumPy will promote almost any other datatype to strings. This applies to array creation or concatenation.
- The array constructors like `np.array()` will use `object` dtype when there is no viable promotion.

- Structured dtypes can promote when their field names and order matches. In that case all fields are promoted individually.
- NumPy `timedelta` can in some cases promote with integers.

Note: Some of these rules are somewhat surprising, and are being considered for change in the future. However, any backward-incompatible changes have to be weighed against the risks of breaking existing code. Please raise an issue if you have particular ideas about how promotion should work.

Details of promoted dtype instances

The above discussion has mainly dealt with the behavior when mixing different DType classes. A dtype instance attached to an array can carry additional information such as byte-order, metadata, string length, or exact structured dtype layout.

While the string length or field names of a structured dtype are important, NumPy considers byte-order, metadata, and the exact layout of a structured dtype as storage details.

During promotion NumPy does *not* take these storage details into account:

- Byte-order is converted to native byte-order.
- Metadata attached to the dtype may or may not be preserved.
- Resulting structured dtypes will be packed (but aligned if inputs were).

This behavior is the best behavior for most programs where storage details are not relevant to the final results and where the use of incorrect byte-order could drastically slow down evaluation.

1.2.5 Iterating over arrays

Note: Arrays support the iterator protocol and can be iterated over like Python lists. See the [quickstart.indexing-slicing-and-iterating](#) section in the Quickstart guide for basic usage and examples. The remainder of this document presents the `nditer` object and covers more advanced usage.

The iterator object `nditer`, introduced in NumPy 1.6, provides many flexible ways to visit all the elements of one or more arrays in a systematic fashion. This page introduces some basic ways to use the object for computations on arrays in Python, then concludes with how one can accelerate the inner loop in Cython. Since the Python exposure of `nditer` is a relatively straightforward mapping of the C array iterator API, these ideas will also provide help working with array iteration from C or C++.

Single array iteration

The most basic task that can be done with the `nditer` is to visit every element of an array. Each element is provided one by one using the standard Python iterator interface.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(6).reshape(2,3)
>>> for x in np.nditer(a):
...     print(x, end=' ')
...
0 1 2 3 4 5
```

An important thing to be aware of for this iteration is that the order is chosen to match the memory layout of the array instead of using a standard C or Fortran ordering. This is done for access efficiency, reflecting the idea that by default one simply wants to visit each element without concern for a particular ordering. We can see this by iterating over the transpose of our previous array, compared to taking a copy of that transpose in C order.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(6).reshape(2,3)
>>> for x in np.nditer(a.T):
...     print(x, end=' ')
...
0 1 2 3 4 5
```

```
>>> for x in np.nditer(a.T.copy(order='C')):
...     print(x, end=' ')
...
0 3 1 4 2 5
```

The elements of both *a* and *a.T* get traversed in the same order, namely the order they are stored in memory, whereas the elements of *a.T.copy(order='C')* get visited in a different order because they have been put into a different memory layout.

Controlling iteration order

There are times when it is important to visit the elements of an array in a specific order, irrespective of the layout of the elements in memory. The `nditer` object provides an *order* parameter to control this aspect of iteration. The default, having the behavior described above, is *order='K'* to keep the existing order. This can be overridden with *order='C'* for C order and *order='F'* for Fortran order.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(6).reshape(2,3)
>>> for x in np.nditer(a, order='F'):
...     print(x, end=' ')
...
0 3 1 4 2 5
>>> for x in np.nditer(a.T, order='C'):
...     print(x, end=' ')
...
0 3 1 4 2 5
```

Modifying array values

By default, the `nditer` treats the input operand as a read-only object. To be able to modify the array elements, you must specify either read-write or write-only mode using the `'readwrite'` or `'writeonly'` per-operand flags.

The `nditer` will then yield writeable buffer arrays which you may modify. However, because the `nditer` must copy this buffer data back to the original array once iteration is finished, you must signal when the iteration is ended, by one of two methods. You may either:

- used the `nditer` as a context manager using the `with` statement, and the temporary data will be written back when the context is exited.
- call the iterator's `close` method once finished iterating, which will trigger the write-back.

The `nditer` can no longer be iterated once either `close` is called or its context is exited.

Example

```
>>> import numpy as np

>>> a = np.arange(6).reshape(2,3)
>>> a
array([[0, 1, 2],
       [3, 4, 5]])
>>> with np.nditer(a, op_flags=['readwrite']) as it:
...     for x in it:
...         x[...] = 2 * x
...
>>> a
array([[ 0,  2,  4],
       [ 6,  8, 10]])
```

If you are writing code that needs to support older versions of `numpy`, note that prior to 1.15, `nditer` was not a context manager and did not have a `close` method. Instead it relied on the destructor to initiate the writeback of the buffer.

Using an external loop

In all the examples so far, the elements of `a` are provided by the iterator one at a time, because all the looping logic is internal to the iterator. While this is simple and convenient, it is not very efficient. A better approach is to move the one-dimensional innermost loop into your code, external to the iterator. This way, NumPy's vectorized operations can be used on larger chunks of the elements being visited.

The `nditer` will try to provide chunks that are as large as possible to the inner loop. By forcing 'C' and 'F' order, we get different external loop sizes. This mode is enabled by specifying an iterator flag.

Observe that with the default of keeping native memory order, the iterator is able to provide a single one-dimensional chunk, whereas when forcing Fortran order, it has to provide three chunks of two elements each.

Example

```
>>> import numpy as np

>>> a = np.arange(6).reshape(2,3)
>>> for x in np.nditer(a, flags=['external_loop']):
...     print(x, end=' ')
...
[0 1 2 3 4 5]
```

```
>>> for x in np.nditer(a, flags=['external_loop'], order='F'):
...     print(x, end=' ')
...
[0 3] [1 4] [2 5]
```

Tracking an index or multi-index

During iteration, you may want to use the index of the current element in a computation. For example, you may want to visit the elements of an array in memory order, but use a C-order, Fortran-order, or multidimensional index to look up values in a different array.

The index is tracked by the iterator object itself, and accessible through the *index* or *multi_index* properties, depending on what was requested. The examples below show printouts demonstrating the progression of the index:

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(6).reshape(2,3)
>>> it = np.nditer(a, flags=['f_index'])
>>> for x in it:
...     print("%d <%d>" % (x, it.index), end=' ')
...
0 <0> 1 <2> 2 <4> 3 <1> 4 <3> 5 <5>
```

```
>>> it = np.nditer(a, flags=['multi_index'])
>>> for x in it:
...     print("%d <%s>" % (x, it.multi_index), end=' ')
...
0 <(0, 0)> 1 <(0, 1)> 2 <(0, 2)> 3 <(1, 0)> 4 <(1, 1)> 5 <(1, 2)>
```

```
>>> with np.nditer(a, flags=['multi_index'], op_flags=['writeonly']) as it:
...     for x in it:
...         x[...] = it.multi_index[1] - it.multi_index[0]
...
>>> a
array([[ 0,  1,  2],
       [-1,  0,  1]])
```

Tracking an index or multi-index is incompatible with using an external loop, because it requires a different index value per element. If you try to combine these flags, the *nditer* object will raise an exception.

Example

```
>>> import numpy as np
```

```
>>> a = np.zeros((2,3))
>>> it = np.nditer(a, flags=['c_index', 'external_loop'])
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Iterator flag EXTERNAL_LOOP cannot be used if an index or multi-index is_
↳being tracked
```

Alternative looping and element access

To make its properties more readily accessible during iteration, `nditer` has an alternative syntax for iterating, which works explicitly with the iterator object itself. With this looping construct, the current value is accessible by indexing into the iterator. Other properties, such as tracked indices remain as before. The examples below produce identical results to the ones in the previous section.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(6).reshape(2,3)
>>> it = np.nditer(a, flags=['f_index'])
>>> while not it.finished:
...     print("%d <%d>" % (it[0], it.index), end=' ')
...     is_not_finished = it.iternext()
...
0 <0> 1 <2> 2 <4> 3 <1> 4 <3> 5 <5>
```

```
>>> it = np.nditer(a, flags=['multi_index'])
>>> while not it.finished:
...     print("%d <%s>" % (it[0], it.multi_index), end=' ')
...     is_not_finished = it.iternext()
...
0 <(0, 0)> 1 <(0, 1)> 2 <(0, 2)> 3 <(1, 0)> 4 <(1, 1)> 5 <(1, 2)>
```

```
>>> with np.nditer(a, flags=['multi_index'], op_flags=['writeonly']) as it:
...     while not it.finished:
...         it[0] = it.multi_index[1] - it.multi_index[0]
...         is_not_finished = it.iternext()
...
>>> a
array([[ 0,  1,  2],
       [-1,  0,  1]])
```

Buffering the array elements

When forcing an iteration order, we observed that the external loop option may provide the elements in smaller chunks because the elements can't be visited in the appropriate order with a constant stride. When writing C code, this is generally fine, however in pure Python code this can cause a significant reduction in performance.

By enabling buffering mode, the chunks provided by the iterator to the inner loop can be made larger, significantly reducing the overhead of the Python interpreter. In the example forcing Fortran iteration order, the inner loop gets to see all the elements in one go when buffering is enabled.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(6).reshape(2,3)
>>> for x in np.nditer(a, flags=['external_loop'], order='F'):
...     print(x, end=' ')
...
[0 3] [1 4] [2 5]
```

```
>>> for x in np.nditer(a, flags=['external_loop', 'buffered'], order='F'):
...     print(x, end=' ')
...
[0 3 1 4 2 5]
```

Iterating as a specific data type

There are times when it is necessary to treat an array as a different data type than it is stored as. For instance, one may want to do all computations on 64-bit floats, even if the arrays being manipulated are 32-bit floats. Except when writing low-level C code, it's generally better to let the iterator handle the copying or buffering instead of casting the data type yourself in the inner loop.

There are two mechanisms which allow this to be done, temporary copies and buffering mode. With temporary copies, a copy of the entire array is made with the new data type, then iteration is done in the copy. Write access is permitted through a mode which updates the original array after all the iteration is complete. The major drawback of temporary copies is that the temporary copy may consume a large amount of memory, particularly if the iteration data type has a larger itemsize than the original one.

Buffering mode mitigates the memory usage issue and is more cache-friendly than making temporary copies. Except for special cases, where the whole array is needed at once outside the iterator, buffering is recommended over temporary copying. Within NumPy, buffering is used by the ufuncs and other functions to support flexible inputs with minimal memory overhead.

In our examples, we will treat the input array with a complex data type, so that we can take square roots of negative numbers. Without enabling copies or buffering mode, the iterator will raise an exception if the data type doesn't match precisely.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(6).reshape(2,3) - 3
>>> for x in np.nditer(a, op_dtypes=['complex128']):
...     print(np.sqrt(x), end=' ')
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: Iterator operand required copying or buffering, but neither copying nor
↳buffering was enabled
```

In copying mode, 'copy' is specified as a per-operand flag. This is done to provide control in a per-operand fashion. Buffering mode is specified as an iterator flag.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(6).reshape(2,3) - 3
>>> for x in np.nditer(a, op_flags=['readonly', 'copy'],
...                     op_dtypes=['complex128']):
...     print(np.sqrt(x), end=' ')
...
1.7320508075688772j 1.4142135623730951j 1j 0j (1+0j) (1.4142135623730951+0j)
```

```
>>> for x in np.nditer(a, flags=['buffered'], op_dtypes=['complex128']):
...     print(np.sqrt(x), end=' ')
...
1.7320508075688772j 1.4142135623730951j 1j 0j (1+0j) (1.4142135623730951+0j)
```

The iterator uses NumPy's casting rules to determine whether a specific conversion is permitted. By default, it enforces 'safe' casting. This means, for example, that it will raise an exception if you try to treat a 64-bit float array as a 32-bit float array. In many cases, the rule 'same_kind' is the most reasonable rule to use, since it will allow conversion from 64 to 32-bit float, but not from float to int or from complex to float.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(6.)
>>> for x in np.nditer(a, flags=['buffered'], op_dtypes=['float32']):
...     print(x, end=' ')
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: Iterator operand 0 dtype could not be cast from dtype('float64') to dtype(
↳ 'float32') according to the rule 'safe'
```

```
>>> for x in np.nditer(a, flags=['buffered'], op_dtypes=['float32'],
...                     casting='same_kind'):
...     print(x, end=' ')
...
0.0 1.0 2.0 3.0 4.0 5.0
```

```
>>> for x in np.nditer(a, flags=['buffered'], op_dtypes=['int32'], casting='same_kind
↳ '):
...     print(x, end=' ')
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: Iterator operand 0 dtype could not be cast from dtype('float64') to dtype(
↳ 'int32') according to the rule 'same_kind'
```

One thing to watch out for is conversions back to the original data type when using a read-write or write-only operand. A common case is to implement the inner loop in terms of 64-bit floats, and use 'same_kind' casting to allow the other floating-point types to be processed as well. While in read-only mode, an integer array could be provided, read-write mode will raise an exception because conversion back to the array would violate the casting rule.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(6)
>>> for x in np.nditer(a, flags=['buffered'], op_flags=['readwrite'],
...                     op_dtypes=['float64'], casting='same_kind'):
...     x[...] = x / 2.0
...
...
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
TypeError: Iterator requested dtype could not be cast from dtype('float64') to dtype(
↳ 'int64'), the operand 0 dtype, according to the rule 'same_kind'
```

Broadcasting array iteration

NumPy has a set of rules for dealing with arrays that have differing shapes which are applied whenever functions take multiple operands which combine element-wise. This is called broadcasting. The `nditer` object can apply these rules for you when you need to write such a function.

As an example, we print out the result of broadcasting a one and a two dimensional array together.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(3)
>>> b = np.arange(6).reshape(2,3)
>>> for x, y in np.nditer([a,b]):
...     print("%d:%d" % (x,y), end=' ')
...
0:0 1:1 2:2 0:3 1:4 2:5
```

When a broadcasting error occurs, the iterator raises an exception which includes the input shapes to help diagnose the problem.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(2)
>>> b = np.arange(6).reshape(2,3)
>>> for x, y in np.nditer([a,b]):
...     print("%d:%d" % (x,y), end=' ')
...
Traceback (most recent call last):
...
ValueError: operands could not be broadcast together with shapes (2,) (2,3)
```

Iterator-allocated output arrays

A common case in NumPy functions is to have outputs allocated based on the broadcasting of the input, and additionally have an optional parameter called 'out' where the result will be placed when it is provided. The `nditer` object provides a convenient idiom that makes it very easy to support this mechanism.

We'll show how this works by creating a function `square` which squares its input. Let's start with a minimal function definition excluding 'out' parameter support.

Example

```
>>> import numpy as np

>>> def square(a):
...     with np.nditer([a, None]) as it:
...         for x, y in it:
...             y[...] = x*x
...         return it.operands[1]
...
>>> square([1,2,3])
array([1, 4, 9])
```

By default, the `nditer` uses the flags ‘allocate’ and ‘writeonly’ for operands that are passed in as `None`. This means we were able to provide just the two operands to the iterator, and it handled the rest.

When adding the ‘out’ parameter, we have to explicitly provide those flags, because if someone passes in an array as ‘out’, the iterator will default to ‘readonly’, and our inner loop would fail. The reason ‘readonly’ is the default for input arrays is to prevent confusion about unintentionally triggering a reduction operation. If the default were ‘readwrite’, any broadcasting operation would also trigger a reduction, a topic which is covered later in this document.

While we're at it, let's also introduce the 'no_broadcast' flag, which will prevent the output from being broadcast. This is important, because we only want one input value for each output. Aggregating more than one input value is a reduction operation which requires special handling. It would already raise an error because reductions must be explicitly enabled in an iterator flag, but the error message that results from disabling broadcasting is much more understandable for end-users. To see how to generalize the square function to a reduction, look at the sum of squares function in the section about Cython.

For completeness, we'll also add the 'external_loop' and 'buffered' flags, as these are what you will typically want for performance reasons.

Example

```
>>> import numpy as np

>>> def square(a, out=None):
...     it = np.nditer([a, out],
...                     flags = ['external_loop', 'buffered'],
...                     op_flags = [['readonly'],
...                                  ['writeonly', 'allocate', 'no_broadcast']])
...     with it:
...         for x, y in it:
...             y[...] = x*x
...     return it.operands[1]
... 
```

```
>>> square([1,2,3])
array([1, 4, 9])
```

```
>>> b = np.zeros((3,))
>>> square([1,2,3], out=b)
array([1., 4., 9.])
>>> b
array([1., 4., 9.])
```

```
>>> square(np.arange(6).reshape(2,3), out=b)
Traceback (most recent call last):
...
ValueError: non-broadcastable output operand with shape (3,) doesn't
match the broadcast shape (2,3)
```

Outer product iteration

Any binary operation can be extended to an array operation in an outer product fashion like in *outer*, and the *nditer* object provides a way to accomplish this by explicitly mapping the axes of the operands. It is also possible to do this with *newaxis* indexing, but we will show you how to directly use the *nditer op_axes* parameter to accomplish this with no intermediate views.

We'll do a simple outer product, placing the dimensions of the first operand before the dimensions of the second operand. The *op_axes* parameter needs one list of axes for each operand, and provides a mapping from the iterator's axes to the axes of the operand.

Suppose the first operand is one dimensional and the second operand is two dimensional. The iterator will have three dimensions, so *op_axes* will have two 3-element lists. The first list picks out the one axis of the first operand, and is -1 for the rest of the iterator axes, with a final result of [0, -1, -1]. The second list picks out the two axes of the second operand, but shouldn't overlap with the axes picked out in the first operand. Its list is [-1, 0, 1]. The output operand maps onto the iterator axes in the standard manner, so we can provide None instead of constructing another list.

The operation in the inner loop is a straightforward multiplication. Everything to do with the outer product is handled by the iterator setup.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(3)
>>> b = np.arange(8).reshape(2,4)
>>> it = np.nditer([a, b, None], flags=['external_loop'],
...               op_axes=[[0, -1, -1], [-1, 0, 1], None])
>>> with it:
...     for x, y, z in it:
...         z[...] = x*y
...     result = it.operands[2] # same as z
...
>>> result
array([[ 0,  0,  0,  0],
       [ 0,  0,  0,  0],
       [ 0,  1,  2,  3],
       [ 4,  5,  6,  7]],
      [[ 0,  2,  4,  6],
       [ 8, 10, 12, 14]])
```

Note that once the iterator is closed we can not access operands and must use a reference created inside the context manager.

Reduction iteration

Whenever a writeable operand has fewer elements than the full iteration space, that operand is undergoing a reduction. The `nditer` object requires that any reduction operand be flagged as read-write, and only allows reductions when 'reduce_ok' is provided as an iterator flag.

For a simple example, consider taking the sum of all elements in an array.

Example

```
>>> import numpy as np

>>> a = np.arange(24).reshape(2,3,4)
>>> b = np.array(0)
>>> with np.nditer([a, b], flags=['reduce_ok'],
...               op_flags=[['readonly'], ['readwrite']]) as it:
...     for x,y in it:
...         y[...] += x
...
>>> b
array(276)
>>> np.sum(a)
276
```

Things are a little bit more tricky when combining reduction and allocated operands. Before iteration is started, any reduction operand must be initialized to its starting values. Here's how we can do this, taking sums along the last axis of *a*.

Example

```
>>> import numpy as np

>>> a = np.arange(24).reshape(2,3,4)
>>> it = np.nditer([a, None], flags=['reduce_ok'],
...               op_flags=[['readonly'], ['readwrite', 'allocate']],
...               op_axes=[None, [0,1,-1]])
>>> with it:
...     it.operands[1][...] = 0
...     for x, y in it:
...         y[...] += x
...     result = it.operands[1]
...
>>> result
array([[ 6, 22, 38],
       [54, 70, 86]])
>>> np.sum(a, axis=2)
array([[ 6, 22, 38],
       [54, 70, 86]])
```

To do buffered reduction requires yet another adjustment during the setup. Normally the iterator construction involves copying the first buffer of data from the readable arrays into the buffer. Any reduction operand is readable, so it may be read into a buffer. Unfortunately, initialization of the operand after this buffering operation is complete will not be reflected in the buffer that the iteration starts with, and garbage results will be produced.

The iterator flag “`delay_bufalloc`” is there to allow iterator-allocated reduction operands to exist together with buffering. When this flag is set, the iterator will leave its buffers uninitialized until it receives a reset, after which it will be ready for regular iteration. Here’s how the previous example looks if we also enable buffering.

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(24).reshape(2,3,4)
>>> it = np.nditer([a, None], flags=['reduce_ok',
...                                'buffered', 'delay_bufalloc'],
...               op_flags=[['readonly'], ['readwrite', 'allocate']],
...               op_axes=[None, [0,1,-1]])
>>> with it:
...     it.operands[1][...] = 0
...     it.reset()
...     for x, y in it:
...         y[...] += x
...     result = it.operands[1]
...
>>> result
array([[ 6, 22, 38],
       [54, 70, 86]])
```

Putting the inner loop in Cython

Those who want really good performance out of their low level operations should strongly consider directly using the iteration API provided in C, but for those who are not comfortable with C or C++, Cython is a good middle ground with reasonable performance tradeoffs. For the `nditer` object, this means letting the iterator take care of broadcasting, dtype conversion, and buffering, while giving the inner loop to Cython.

For our example, we’ll create a sum of squares function. To start, let’s implement this function in straightforward Python. We want to support an ‘axis’ parameter similar to the numpy `sum` function, so we will need to construct a list for the `op_axes` parameter. Here’s how this looks.

Example

```
>>> def axis_to_axeslist(axis, ndim):
...     if axis is None:
...         return [-1] * ndim
...     else:
...         if type(axis) is not tuple:
...             axis = (axis,)
...         axeslist = [1] * ndim
...         for i in axis:
...             axeslist[i] = -1
...         ax = 0
...         for i in range(ndim):
```

(continues on next page)

(continued from previous page)

```

...         if axeslist[i] != -1:
...             axeslist[i] = ax
...             ax += 1
...         return axeslist
...
>>> def sum_squares_py(arr, axis=None, out=None):
...     axeslist = axis_to_axeslist(axis, arr.ndim)
...     it = np.nditer([arr, out], flags=['reduce_ok',
...                                     'buffered', 'delay_bufalloc'],
...                   op_flags=[['readonly'], ['readwrite', 'allocate']],
...                   op_axes=[None, axeslist],
...                   op_dtypes=['float64', 'float64'])
...     with it:
...         it.operands[1][...] = 0
...         it.reset()
...         for x, y in it:
...             y[...] += x*x
...         return it.operands[1]
...
>>> a = np.arange(6).reshape(2,3)
>>> sum_squares_py(a)
array(55.)
>>> sum_squares_py(a, axis=-1)
array([ 5., 50.])

```

To Cython-ize this function, we replace the inner loop (`y[...] += x*x`) with Cython code that's specialized for the `float64` dtype. With the `'external_loop'` flag enabled, the arrays provided to the inner loop will always be one-dimensional, so very little checking needs to be done.

Here's the listing of `sum_squares.pyx`:

```

import numpy as np
cimport numpy as np
cimport cython

def axis_to_axeslist(axis, ndim):
    if axis is None:
        return [-1] * ndim
    else:
        if type(axis) is not tuple:
            axis = (axis,)
        axeslist = [1] * ndim
        for i in axis:
            axeslist[i] = -1
        ax = 0
        for i in range(ndim):
            if axeslist[i] != -1:
                axeslist[i] = ax
                ax += 1
        return axeslist

@cython.boundscheck(False)
def sum_squares_cy(arr, axis=None, out=None):
    cdef np.ndarray[double] x
    cdef np.ndarray[double] y
    cdef int size

```

(continues on next page)

(continued from previous page)

```

cdef double value

axeslist = axis_to_axeslist(axis, arr.ndim)
it = np.nditer([arr, out], flags=['reduce_ok', 'external_loop',
                                'buffered', 'delay_bufalloc'],
               op_flags=[['readonly'], ['readwrite', 'allocate']],
               op_axes=[None, axeslist],
               op_dtypes=['float64', 'float64'])

with it:
    it.operands[1][...] = 0
    it.reset()
    for xarr, yarr in it:
        x = xarr
        y = yarr
        size = x.shape[0]
        for i in range(size):
            value = x[i]
            y[i] = y[i] + value * value
    return it.operands[1]

```

On this machine, building the .pyx file into a module looked like the following, but you may have to find some Cython tutorials to tell you the specifics for your system configuration.:

```

$ cython sum_squares.pyx
$ gcc -shared -pthread -fPIC -fwrapv -O2 -Wall -I/usr/include/python2.7 -fno-strict-
  ↳aliasing -o sum_squares.so sum_squares.c

```

Running this from the Python interpreter produces the same answers as our native Python/NumPy code did.

Example

```

>>> from sum_squares import sum_squares_cy
>>> a = np.arange(6).reshape(2,3)
>>> sum_squares_cy(a)
array(55.0)
>>> sum_squares_cy(a, axis=-1)
array([ 5., 50.])

```

Doing a little timing in IPython shows that the reduced overhead and memory allocation of the Cython inner loop is providing a very nice speedup over both the straightforward Python code and an expression using NumPy's built-in sum function.:

```

>>> a = np.random.rand(1000,1000)

>>> timeit sum_squares_py(a, axis=-1)
10 loops, best of 3: 37.1 ms per loop

>>> timeit np.sum(a*a, axis=-1)
10 loops, best of 3: 20.9 ms per loop

>>> timeit sum_squares_cy(a, axis=-1)
100 loops, best of 3: 11.8 ms per loop

>>> np.all(sum_squares_cy(a, axis=-1) == np.sum(a*a, axis=-1))

```

(continues on next page)

(continued from previous page)

```
True
>>> np.all(sum_squares_py(a, axis=-1) == np.sum(a*a, axis=-1))
True
```

1.2.6 Standard array subclasses

Note: Subclassing a `numpy.ndarray` is possible but if your goal is to create an array with *modified* behavior, as do dask arrays for distributed computation and cupy arrays for GPU-based computation, subclassing is discouraged. Instead, using numpy's dispatch mechanism is recommended.

The `ndarray` can be inherited from (in Python or in C) if desired. Therefore, it can form a foundation for many useful classes. Often whether to sub-class the array object or to simply use the core array component as an internal part of a new class is a difficult decision, and can be simply a matter of choice. NumPy has several tools for simplifying how your new object interacts with other array objects, and so the choice may not be significant in the end. One way to simplify the question is by asking yourself if the object you are interested in can be replaced as a single array or does it really require two or more arrays at its core.

Note that `asarray` always returns the base-class `ndarray`. If you are confident that your use of the array object can handle any subclass of an `ndarray`, then `asanyarray` can be used to allow subclasses to propagate more cleanly through your subroutine. In principle, a subclass could redefine any aspect of the array and therefore, under strict guidelines, `asanyarray` would rarely be useful. However, most subclasses of the array object will not redefine certain aspects of the array object such as the buffer interface, or the attributes of the array. One important example, however, of why your subroutine may not be able to handle an arbitrary subclass of an array is that matrices redefine the “*” operator to be matrix-multiplication, rather than element-by-element multiplication.

Special attributes and methods

See also:

Subclassing ndarray

NumPy provides several hooks that classes can customize:

```
class.__array_ufunc__ (ufunc, method, *inputs, **kwargs)
```

Any class, `ndarray` subclass or not, can define this method or set it to `None` in order to override the behavior of NumPy's ufuncs. This works quite similarly to Python's `__mul__` and other binary operation routines.

- `ufunc` is the ufunc object that was called.
- `method` is a string indicating which Ufunc method was called (one of `"__call__"`, `"reduce"`, `"reduceat"`, `"accumulate"`, `"outer"`, `"inner"`).
- `inputs` is a tuple of the input arguments to the ufunc.
- `kwargs` is a dictionary containing the optional input arguments of the ufunc. If given, any `out` arguments, both positional and keyword, are passed as a tuple in `kwargs`. See the discussion in *Universal functions (ufunc)* for details.

The method should return either the result of the operation, or `NotImplemented` if the operation requested is not implemented.

If one of the input, output, or `where` arguments has a `__array_ufunc__` method, it is executed *instead* of the ufunc. If more than one of the arguments implements `__array_ufunc__`, they are tried in the order: subclasses

before superclasses, inputs before outputs, outputs before `where`, otherwise left to right. The first routine returning something other than `NotImplemented` determines the result. If all of the `__array_ufunc__` operations return `NotImplemented`, a `TypeError` is raised.

Note: We intend to re-implement numpy functions as (generalized) Ufunc, in which case it will become possible for them to be overridden by the `__array_ufunc__` method. A prime candidate is `matmul`, which currently is not a Ufunc, but could be relatively easily be rewritten as a (set of) generalized Ufuncs. The same may happen with functions such as `median`, `amin`, and `argsort`.

Like with some other special methods in python, such as `__hash__` and `__iter__`, it is possible to indicate that your class does *not* support ufuncs by setting `__array_ufunc__ = None`. Ufuncs always raise `TypeError` when called on an object that sets `__array_ufunc__ = None`.

The presence of `__array_ufunc__` also influences how `ndarray` handles binary operations like `arr + obj` and `arr < obj` when `arr` is an `ndarray` and `obj` is an instance of a custom class. There are two possibilities. If `obj.__array_ufunc__` is present and not `None`, then `ndarray.__add__` and friends will delegate to the ufunc machinery, meaning that `arr + obj` becomes `np.add(arr, obj)`, and then `add` invokes `obj.__array_ufunc__`. This is useful if you want to define an object that acts like an array.

Alternatively, if `obj.__array_ufunc__` is set to `None`, then as a special case, special methods like `ndarray.__add__` will notice this and *unconditionally* raise `TypeError`. This is useful if you want to create objects that interact with arrays via binary operations, but are not themselves arrays. For example, a units handling system might have an object `m` representing the “meters” unit, and want to support the syntax `arr * m` to represent that the array has units of “meters”, but not want to otherwise interact with arrays via ufuncs or otherwise. This can be done by setting `__array_ufunc__ = None` and defining `__mul__` and `__rmul__` methods. (Note that this means that writing an `__array_ufunc__` that always returns `NotImplemented` is not quite the same as setting `__array_ufunc__ = None`: in the former case, `arr + obj` will raise `TypeError`, while in the latter case it is possible to define a `__radd__` method to prevent this.)

The above does not hold for in-place operators, for which `ndarray` never returns `NotImplemented`. Hence, `arr += obj` would always lead to a `TypeError`. This is because for arrays in-place operations cannot generically be replaced by a simple reverse operation. (For instance, by default, `arr += obj` would be translated to `arr = arr + obj`, i.e., `arr` would be replaced, contrary to what is expected for in-place array operations.)

Note: If you define `__array_ufunc__`:

- If you are not a subclass of `ndarray`, we recommend your class define special methods like `__add__` and `__lt__` that delegate to ufuncs just like `ndarray` does. An easy way to do this is to subclass from `NDArrayOperatorsMixin`.
- If you subclass `ndarray`, we recommend that you put all your override logic in `__array_ufunc__` and not also override special methods. This ensures the class hierarchy is determined in only one place rather than separately by the ufunc machinery and by the binary operation rules (which gives preference to special methods of subclasses; the alternative way to enforce a one-place only hierarchy, of setting `__array_ufunc__` to `None`, would seem very unexpected and thus confusing, as then the subclass would not work at all with ufuncs).
- `ndarray` defines its own `__array_ufunc__`, which, evaluates the ufunc if no arguments have overrides, and returns `NotImplemented` otherwise. This may be useful for subclasses for which `__array_ufunc__` converts any instances of its own class to `ndarray`: it can then pass these on to its superclass using `super().__array_ufunc__(*inputs, **kwargs)`, and finally return the results after possible back-conversion. The advantage of this practice is that it ensures that it is possible to have a hierarchy of subclasses that extend the behaviour. See Subclassing `ndarray` for details.

```
class.__array_function__ (func, types, args, kwargs)
```

- `func` is an arbitrary callable exposed by NumPy's public API, which was called in the form `func(*args, **kwargs)`.
- `types` is a collection `collections.abc.Collection` of unique argument types from the original NumPy function call that implement `__array_function__`.
- The tuple `args` and dict `kwargs` are directly passed on from the original call.

As a convenience for `__array_function__` implementers, `types` provides all argument types with an `'__array_function__'` attribute. This allows implementers to quickly identify cases where they should defer to `__array_function__` implementations on other arguments. Implementations should not rely on the iteration order of `types`.

Most implementations of `__array_function__` will start with two checks:

1. Is the given function something that we know how to overload?
2. Are all arguments of a type that we know how to handle?

If these conditions hold, `__array_function__` should return the result from calling its implementation for `func(*args, **kwargs)`. Otherwise, it should return the sentinel value `NotImplemented`, indicating that the function is not implemented by these types.

There are no general requirements on the return value from `__array_function__`, although most sensible implementations should probably return array(s) with the same type as one of the function's arguments.

It may also be convenient to define a custom decorators (implements below) for registering `__array_function__` implementations.

```
HANDLED_FUNCTIONS = {}

class MyArray:
    def __array_function__(self, func, types, args, kwargs):
        if func not in HANDLED_FUNCTIONS:
            return NotImplemented
        # Note: this allows subclasses that don't override
        # __array_function__ to handle MyArray objects
        if not all(issubclass(t, MyArray) for t in types):
            return NotImplemented
        return HANDLED_FUNCTIONS[func](*args, **kwargs)

    def implements(numpy_function):
        """Register an __array_function__ implementation for MyArray objects."""
        def decorator(func):
            HANDLED_FUNCTIONS[numpy_function] = func
            return func
        return decorator

    @implements(np.concatenate)
    def concatenate(arrays, axis=0, out=None):
        ... # implementation of concatenate for MyArray objects

    @implements(np.broadcast_to)
    def broadcast_to(array, shape):
        ... # implementation of broadcast_to for MyArray objects
```

Note that it is not required for `__array_function__` implementations to include *all* of the corresponding NumPy function's optional arguments (e.g., `broadcast_to` above omits the irrelevant `subok` argument). Optional arguments are only passed in to `__array_function__` if they were explicitly used in the NumPy function call.

Just like the case for builtin special methods like `__add__`, properly written `__array_function__` methods should always return `NotImplemented` when an unknown type is encountered. Otherwise, it will be impossible to correctly override NumPy functions from another object if the operation also includes one of your objects.

For the most part, the rules for dispatch with `__array_function__` match those for `__array_ufunc__`. In particular:

- NumPy will gather implementations of `__array_function__` from all specified inputs and call them in order: subclasses before superclasses, and otherwise left to right. Note that in some edge cases involving subclasses, this differs slightly from the [current behavior](#) of Python.
- Implementations of `__array_function__` indicate that they can handle the operation by returning any value other than `NotImplemented`.
- If all `__array_function__` methods return `NotImplemented`, NumPy will raise `TypeError`.

If no `__array_function__` methods exists, NumPy will default to calling its own implementation, intended for use on NumPy arrays. This case arises, for example, when all array-like arguments are Python numbers or lists. (NumPy arrays do have a `__array_function__` method, given below, but it always returns `NotImplemented` if any argument other than a NumPy array subclass implements `__array_function__`.)

One deviation from the current behavior of `__array_ufunc__` is that NumPy will only call `__array_function__` on the *first* argument of each unique type. This matches Python's [rule for calling reflected methods](#), and this ensures that checking overloads has acceptable performance even when there are a large number of overloaded arguments.

```
class.__array_finalize__(obj)
```

This method is called whenever the system internally allocates a new array from *obj*, where *obj* is a subclass (sub-type) of the `ndarray`. It can be used to change attributes of *self* after construction (so as to ensure a 2-d matrix for example), or to update meta-information from the “parent.” Subclasses inherit a default implementation of this method that does nothing.

```
class.__array_wrap__(array, context=None, return_scalar=False)
```

At the end of every ufunc, this method is called on the input object with the highest array priority, or the output object if one was specified. The ufunc-computed array is passed in and whatever is returned is passed to the user. Subclasses inherit a default implementation of this method, which transforms the array into a new instance of the object's class. Subclasses may opt to use this method to transform the output array into an instance of the subclass and update metadata before returning the array to the user.

NumPy may also call this function without a context from non-ufuncs to allow preserving subclass information.

Changed in version 2.0: `return_scalar` is now passed as either `False` (usually) or `True` indicating that NumPy would return a scalar. Subclasses may ignore the value, or return `array[()]` to behave more like NumPy.

Note: It is hoped to eventually deprecate this method in favour of `__array_ufunc__` for ufuncs (and `__array_function__` for a few other functions like `numpy.squeeze`).

```
class.__array_priority__
```

The value of this attribute is used to determine what type of object to return in situations where there is more than one possibility for the Python type of the returned object. Subclasses inherit a default value of 0.0 for this attribute.

Note: For ufuncs, it is hoped to eventually deprecate this method in favour of `__array_ufunc__`.

`class.__array__ (dtype=None, copy=None)`

If defined on an object, it must return a NumPy `ndarray`. This method is called by array-coercion functions like `np.array()` if an object implementing this interface is passed to those functions.

Third-party implementations of `__array__` must take `dtype` and `copy` arguments.

Deprecated since version NumPy: 2.0 Not implementing `copy` and `dtype` is deprecated as of NumPy 2. When adding them, you must ensure correct behavior for `copy`.

- `dtype` is the requested data type of the returned array and is passed by NumPy positionally (only if requested by the user). It is acceptable to ignore the `dtype` because NumPy will check the result and cast to `dtype` if necessary. If it is more efficient to coerce the data to the requested `dtype` without relying on NumPy, you should handle it in your library.
- `copy` is a boolean passed by keyword. If `copy=True` you *must* return a copy. Returning a view into existing data will lead to incorrect user code. If `copy=False` the user requested that a copy is never made and you *must* raise an error unless no copy is made and the returned array is a view into existing data. It is valid to always raise an error for `copy=False`. The default `copy=None` (not passed) allows for the result to either be a view or a copy. However, a view return should be preferred when possible.

Please refer to Interoperability with NumPy for the protocol hierarchy, of which `__array__` is the oldest and least desirable.

Note: If a class (`ndarray` subclass or not) having the `__array__` method is used as the output object of an ufunc, results will *not* be written to the object returned by `__array__`. This practice will return `TypeError`.

Example

Use `__array__` to create a diagonal array of fixed size and value:

```
>>> import numpy as np
>>> class DiagonalArray:
...     def __init__(self, N, value):
...         self._N = N
...         self._i = value
...     def __repr__(self):
...         return f"{self.__class__.__name__}(N={self._N}, value={self._i})"
...     def __array__(self, dtype=None, copy=None):
...         if copy is False:
...             raise ValueError(
...                 "`copy=False` isn't supported. A copy is always created."
...             )
...         return self._i * np.eye(self._N, dtype=dtype)
```

Our custom array can be instantiated like:

```
>>> arr = DiagonalArray(5, 1)
>>> arr
DiagonalArray(N=5, value=1)
```

We can convert to a numpy array using `numpy.array` or `numpy.asarray`, which will call its `__array__` method to obtain a standard `numpy.ndarray`.

```
>>> np.asarray(arr)
array([[1., 0., 0., 0., 0.],
       [0., 1., 0., 0., 0.],
       [0., 0., 1., 0., 0.]
```

(continues on next page)

(continued from previous page)

```
[0., 0., 0., 1., 0.],
[0., 0., 0., 0., 1.]])
```

Using `dtype` should return an appropriate `ndarray` or raise an error:

```
>>> np.asarray(arr, dtype=np.float32)
array([[1., 0., 0., 0., 0.],
       [0., 1., 0., 0., 0.],
       [0., 0., 1., 0., 0.],
       [0., 0., 0., 1., 0.],
       [0., 0., 0., 0., 1.]], dtype=float32)
```

If we operate on `arr` with a numpy function, numpy will again use the `__array__` interface to convert it to an array and then apply the function in the usual way.

```
>>> np.multiply(arr, 2)
array([[2., 0., 0., 0., 0.],
       [0., 2., 0., 0., 0.],
       [0., 0., 2., 0., 0.],
       [0., 0., 0., 2., 0.],
       [0., 0., 0., 0., 2.]])
```

Notice that the return type is a standard `numpy.ndarray`.

```
>>> type(np.multiply(arr, 2))
<class 'numpy.ndarray'>
```

Matrix objects

Note: It is strongly advised *not* to use the matrix subclass. As described below, it makes writing functions that deal consistently with matrices and regular arrays very difficult. Currently, they are mainly used for interacting with `scipy.sparse`. We hope to provide an alternative for this use, however, and eventually remove the `matrix` subclass.

`matrix` objects inherit from the `ndarray` and therefore, they have the same attributes and methods of `ndarrays`. There are six important differences of matrix objects, however, that may lead to unexpected results when you use matrices but expect them to act like arrays:

1. Matrix objects can be created using a string notation to allow Matlab-style syntax where spaces separate columns and semicolons (;) separate rows.
2. Matrix objects are always two-dimensional. This has far-reaching implications, in that `m.ravel()` is still two-dimensional (with a 1 in the first dimension) and item selection returns two-dimensional objects so that sequence behavior is fundamentally different than arrays.
3. Matrix objects over-ride multiplication to be matrix-multiplication. **Make sure you understand this for functions that you may want to receive matrices. Especially in light of the fact that `asanyarray(m)` returns a matrix when `m` is a matrix.**
4. Matrix objects over-ride power to be matrix raised to a power. The same warning about using power inside a function that uses `asanyarray(...)` to get an array object holds for this fact.
5. The default `__array_priority__` of matrix objects is 10.0, and therefore mixed operations with `ndarrays` always produce matrices.

6. Matrices have special attributes which make calculations easier. These are

<code>matrix.T</code>	Returns the transpose of the matrix.
<code>matrix.H</code>	Returns the (complex) conjugate transpose of <i>self</i> .
<code>matrix.I</code>	Returns the (multiplicative) inverse of invertible <i>self</i> .
<code>matrix.A</code>	Return <i>self</i> as an <i>ndarray</i> object.

property

property `matrix.T`

Returns the transpose of the matrix.

Does *not* conjugate! For the complex conjugate transpose, use `.H`.

Parameters

None

Returns

ret

[matrix object] The (non-conjugated) transpose of the matrix.

See also:

[transpose](#), *[getH](#)*

Examples

```
>>> m = np.matrix('[1, 2; 3, 4]')
>>> m
matrix([[1, 2],
        [3, 4]])
>>> m.getT()
matrix([[1, 3],
        [2, 4]])
```

property

property `matrix.H`

Returns the (complex) conjugate transpose of *self*.

Equivalent to `np.transpose(self)` if *self* is real-valued.

Parameters

None

Returns

ret

[matrix object] complex conjugate transpose of *self*

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3,4)))
>>> z = x - 1j*x; z
matrix([[ 0. +0.j,   1. -1.j,   2. -2.j,   3. -3.j],
        [ 4. -4.j,   5. -5.j,   6. -6.j,   7. -7.j],
        [ 8. -8.j,   9. -9.j,  10. -10.j,  11. -11.j]])
>>> z.getH()
matrix([[ 0. -0.j,   4. +4.j,   8. +8.j],
        [ 1. +1.j,   5. +5.j,   9. +9.j],
        [ 2. +2.j,   6. +6.j,  10. +10.j],
        [ 3. +3.j,   7. +7.j,  11. +11.j]])
```

property

property `matrix.I`

Returns the (multiplicative) inverse of invertible *self*.

Parameters

None

Returns

ret

[matrix object] If *self* is non-singular, *ret* is such that `ret * self == self * ret == np.matrix(np.eye(self[0,:].size))` all return True.

Raises

numpy.linalg.LinAlgError: Singular matrix

If *self* is singular.

See also:

[*linalg.inv*](#)

Examples

```
>>> m = np.matrix('[1, 2; 3, 4]'); m
matrix([[1, 2],
        [3, 4]])
>>> m.getI()
matrix([[ -2. ,   1. ],
        [ 1.5,  -0.5]])
>>> m.getI() * m
matrix([[ 1.,   0.], # may vary
        [ 0.,   1.]])
```

property

property `matrix.A`

Return *self* as an [*ndarray*](#) object.

Equivalent to `np.asarray(self)`.

Parameters

None

Returns

ret
[ndarray] *self* as an *ndarray*

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3,4))); x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> x.getA()
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11]])
```

Warning: Matrix objects over-ride multiplication, `*`, and power, `**`, to be matrix-multiplication and matrix power, respectively. If your subroutine can accept sub-classes and you do not convert to base-class arrays, then you must use the ufuncs `multiply` and `power` to be sure that you are performing the correct operation for all inputs.

The matrix class is a Python subclass of the ndarray and can be used as a reference for how to construct your own subclass of the ndarray. Matrices can be created from other matrices, strings, and anything else that can be converted to an ndarray. The name “mat” is an alias for “matrix” in NumPy.

<code>matrix(data[, dtype, copy])</code>	Returns a matrix from an array-like object, or from a string of data.
<code>asmatrix(data[, dtype])</code>	Interpret the input as a matrix.
<code>bmat(obj[, ldict, gdict])</code>	Build a matrix object from a string, nested sequence, or array.

class `numpy.matrix` (*data*, *dtype=None*, *copy=True*)

Returns a matrix from an array-like object, or from a string of data.

A matrix is a specialized 2-D array that retains its 2-D nature through operations. It has certain special operators, such as `*` (matrix multiplication) and `**` (matrix power).

Note: It is no longer recommended to use this class, even for linear algebra. Instead use regular arrays. The class may be removed in the future.

Parameters

data

[array_like or string] If *data* is a string, it is interpreted as a matrix with commas or spaces separating columns, and semicolons separating rows.

dtype

[data-type] Data-type of the output matrix.

copy

[bool] If *data* is already an *ndarray*, then this flag determines whether the data is copied (the default), or whether a view is constructed.

Attributes

A

Return *self* as an *ndarray* object.

A1

Return *self* as a flattened *ndarray*.

H

Returns the (complex) conjugate transpose of *self*.

I

Returns the (multiplicative) inverse of invertible *self*.

T

Returns the transpose of the matrix.

base

Base object if memory is from some other object.

ctypes

An object to simplify the interaction of the array with the ctypes module.

data

Python buffer object pointing to the start of the array's data.

device

dtype

Data-type of the array's elements.

flags

Information about the memory layout of the array.

flat

A 1-D iterator over the array.

imag

The imaginary part of the array.

itemsize

Length of one array element in bytes.

mT

View of the matrix transposed array.

nbytes

Total bytes consumed by the elements of the array.

ndim

Number of array dimensions.

real

The real part of the array.

shape

Tuple of array dimensions.

size

Number of elements in the array.

strides

Tuple of bytes to step in each dimension when traversing an array.

Methods

<code>all([axis, out])</code>	Test whether all matrix elements along a given axis evaluate to True.
<code>any([axis, out])</code>	Test whether any array element along a given axis evaluates to True.
<code>argmax([axis, out])</code>	Indexes of the maximum values along an axis.
<code>argmin([axis, out])</code>	Indexes of the minimum values along an axis.
<code>argpartition(kth[, axis, kind, order])</code>	Returns the indices that would partition this array.
<code>argsort([axis, kind, order, stable, descending])</code>	Returns the indices that would sort this array.
<code>astype(dtype[, order, casting, subok, copy])</code>	Copy of the array, cast to a specified type.
<code>byteswap(inplace)</code>	Swap the bytes of the array elements
<code>choose(choices[, out, mode])</code>	Use an index array to construct a new array from a set of choices.
<code>clip([min, max, out])</code>	Return an array whose values are limited to <code>[min, max]</code> .
<code>compress(condition[, axis, out])</code>	Return selected slices of this array along given axis.
<code>conj()</code>	Complex-conjugate all elements.
<code>conjugate()</code>	Return the complex conjugate, element-wise.
<code>copy([order])</code>	Return a copy of the array.
<code>cumprod([axis, dtype, out])</code>	Return the cumulative product of the elements along the given axis.
<code>cumsum([axis, dtype, out])</code>	Return the cumulative sum of the elements along the given axis.
<code>diagonal([offset, axis1, axis2])</code>	Return specified diagonals.
<code>dot(other, /[, out])</code>	Refer to <code>numpy.dot</code> for full documentation.
<code>dump(file)</code>	Dump a pickle of the array to the specified file.
<code>dumps()</code>	Returns the pickle of the array as a string.
<code>fill(value)</code>	Fill the array with a scalar value.
<code>flatten([order])</code>	Return a flattened copy of the matrix.
<code>getA()</code>	Return <code>self</code> as an <code>ndarray</code> object.
<code>getA1()</code>	Return <code>self</code> as a flattened <code>ndarray</code> .
<code>getH()</code>	Returns the (complex) conjugate transpose of <code>self</code> .
<code>getI()</code>	Returns the (multiplicative) inverse of invertible <code>self</code> .
<code>getT()</code>	Returns the transpose of the matrix.
<code>getfield(dtype[, offset])</code>	Returns a field of the given array as a certain type.
<code>item(*args)</code>	Copy an element of an array to a standard Python scalar and return it.
<code>max([axis, out])</code>	Return the maximum value along an axis.
<code>mean([axis, dtype, out])</code>	Returns the average of the matrix elements along the given axis.
<code>min([axis, out])</code>	Return the minimum value along an axis.
<code>nonzero()</code>	Return the indices of the elements that are non-zero.
<code>partition(kth[, axis, kind, order])</code>	Partially sorts the elements in the array in such a way that the value of the element in k-th position is in the position it would be in a sorted array.
<code>prod([axis, dtype, out])</code>	Return the product of the array elements over the given axis.
<code>ptp([axis, out])</code>	Peak-to-peak (maximum - minimum) value along the given axis.
<code>put(indices, values[, mode])</code>	Set <code>a.flat[n] = values[n]</code> for all <code>n</code> in indices.
<code>ravel([order])</code>	Return a flattened matrix.

continues on next page

Table 7 – continued from previous page

<code>repeat(repeats[, axis])</code>	Repeat elements of an array.
<code>reshape(a.reshape)</code>	Returns an array containing the same data with a new shape.
<code>resize(a.resize)</code>	Change shape and size of array in-place.
<code>round([decimals, out])</code>	Return <i>a</i> with each element rounded to the given number of decimals.
<code>searchsorted(v[, side, sorter])</code>	Find indices where elements of <i>v</i> should be inserted in <i>a</i> to maintain order.
<code>setfield(val, dtype[, offset])</code>	Put a value into a specified place in a field defined by a data-type.
<code>setflags([write, align, uic])</code>	Set array flags WRITEABLE, ALIGNED, WRITE-BACKIFCOPY, respectively.
<code>sort([axis, kind, order, stable, descending])</code>	Sort an array in-place.
<code>squeeze([axis])</code>	Return a possibly reshaped matrix.
<code>std([axis, dtype, out, ddof])</code>	Return the standard deviation of the array elements along the given axis.
<code>sum([axis, dtype, out])</code>	Returns the sum of the matrix elements, along the given axis.
<code>swapaxes(axis1, axis2, /)</code>	Return a view of the array with <i>axis1</i> and <i>axis2</i> interchanged.
<code>take(indices[, axis, out, mode])</code>	Return an array formed from the elements of <i>a</i> at the given indices.
<code>to_device(device, /, *[, stream])</code>	For Array API compatibility.
<code>tobytes([order])</code>	Construct Python bytes containing the raw data bytes in the array.
<code>tofile(fid, /[, sep, format])</code>	Write array to a file as text or binary (default).
<code>tolist()</code>	Return the matrix as a (possibly nested) list.
<code>trace([offset, axis1, axis2, dtype, out])</code>	Return the sum along diagonals of the array.
<code>transpose(*axes)</code>	Returns a view of the array with axes transposed.
<code>var([axis, dtype, out, ddof])</code>	Returns the variance of the matrix elements, along the given axis.
<code>view([dtype][, type])</code>	New view of array with the same data.

method

`matrix.all (axis=None, out=None)`

Test whether all matrix elements along a given axis evaluate to True.

Parameters

See ``numpy.all`` for complete descriptions

See also:

`numpy.all`

Notes

This is the same as `ndarray.all`, but it returns a `matrix` object.

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3,4))); x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> y = x[0]; y
matrix([[0, 1, 2, 3]])
>>> (x == y)
matrix([[ True,  True,  True,  True],
        [False, False, False, False],
        [False, False, False, False]])
>>> (x == y).all()
False
>>> (x == y).all(0)
matrix([[False, False, False, False]])
>>> (x == y).all(1)
matrix([[ True],
        [False],
        [False]])
```

method

`matrix.any` (*axis=None, out=None*)

Test whether any array element along a given axis evaluates to True.

Refer to `numpy.any` for full documentation.

Parameters

axis

[int, optional] Axis along which logical OR is performed

out

[ndarray, optional] Output to existing array instead of creating new one, must have same shape as expected output

Returns

any

[bool, ndarray] Returns a single bool if *axis* is None; otherwise, returns `ndarray`

method

`matrix.argmax` (*axis=None, out=None*)

Indexes of the maximum values along an axis.

Return the indexes of the first occurrences of the maximum values along the specified axis. If *axis* is None, the index is for the flattened matrix.

Parameters

See ``numpy.argmax`` for complete descriptions

See also:

`numpy.argmax`

Notes

This is the same as `ndarray.argmax`, but returns a *matrix* object where `ndarray.argmax` would return an *ndarray*.

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3,4))); x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> x.argmax()
11
>>> x.argmax(0)
matrix([[2, 2, 2, 2]])
>>> x.argmax(1)
matrix([[3],
        [3],
        [3]])
```

method

`matrix.argmaxin` (*axis=None, out=None*)

Indexes of the minimum values along an axis.

Return the indexes of the first occurrences of the minimum values along the specified axis. If axis is None, the index is for the flattened matrix.

Parameters

See ``numpy.argmaxin`` for complete descriptions.

See also:

`numpy.argmaxin`

Notes

This is the same as `ndarray.argmaxin`, but returns a *matrix* object where `ndarray.argmaxin` would return an *ndarray*.

Examples

```
>>> x = -np.matrix(np.arange(12).reshape((3,4))); x
matrix([[ 0, -1, -2, -3],
        [-4, -5, -6, -7],
        [-8, -9, -10, -11]])
>>> x.argmaxin()
11
>>> x.argmaxin(0)
matrix([[2, 2, 2, 2]])
>>> x.argmaxin(1)
matrix([[3],
        [3],
        [3]])
```

method

`matrix.argmaxpartition` (*kth*, *axis=-1*, *kind='introselect'*, *order=None*)

Returns the indices that would partition this array.

Refer to [`numpy.argmaxpartition`](#) for full documentation.

See also:

[`numpy.argmaxpartition`](#)

equivalent function

method

`matrix.argsort` (*axis=-1*, *kind=None*, *order=None*, ***, *stable=None*, *descending=None*)

Returns the indices that would sort this array.

Refer to [`numpy.argsort`](#) for full documentation.

See also:

[`numpy.argsort`](#)

equivalent function

method

`matrix.astype` (*dtype*, *order='K'*, *casting='unsafe'*, *subok=True*, *copy=True*)

Copy of the array, cast to a specified type.

Parameters

dtype

[str or dtype] Typecode or data-type to which the array is cast.

order

[[*'C'*, *'F'*, *'A'*, *'K'*], optional] Controls the memory layout order of the result. *'C'* means C order, *'F'* means Fortran order, *'A'* means *'F'* order if all the arrays are Fortran contiguous, *'C'* order otherwise, and *'K'* means as close to the order the array elements appear in memory as possible. Default is *'K'*.

casting

[[*'no'*, *'equiv'*, *'safe'*, *'same_kind'*, *'same_value'*, *'unsafe'*], optional] Controls what kind of data casting may occur. Defaults to *'unsafe'* for backwards compatibility.

- *'no'* means the data types should not be cast at all.
- *'equiv'* means only byte-order changes are allowed.
- *'safe'* means only casts which can preserve values are allowed.
- *'same_kind'* means only safe casts or casts within a kind, like float64 to float32, are allowed.
- *'unsafe'* means any data conversions may be done.
- *'same_value'* means any data conversions may be done, but the values must not change, including rounding of floats or overflow of ints

New in version 2.4: Support for *'same_value'* was added.

subok

[bool, optional] If True, then sub-classes will be passed-through (default), otherwise the returned array will be forced to be a base-class array.

copy

[bool, optional] By default, `astype` always returns a newly allocated array. If this is set to false, and the *dtype*, *order*, and *subok* requirements are satisfied, the input array is returned instead of a copy.

Returns**arr_t**

[ndarray] Unless *copy* is False and the other conditions for returning the input array are satisfied (see description for *copy* input parameter), *arr_t* is a new array of the same shape as the input array, with dtype, order given by *dtype*, *order*.

Raises**ComplexWarning**

When casting from complex to float or int. To avoid this, one should use `a.real.astype(t)`.

ValueError

When casting using 'same_value' and the values change or would overflow

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 2.5])
>>> x
array([1. ,  2. ,  2.5])
```

```
>>> x.astype(np.int_)
array([1, 2, 2])
```

```
>>> x.astype(np.int_, casting="same_value")
Traceback (most recent call last):
...
ValueError: could not cast 'same_value' double to long
```

```
>>> x[:2].astype(np.int_, casting="same_value")
array([1, 2])
```

method

`matrix.byteswap(inplace=False)`

Swap the bytes of the array elements

Toggle between low-endian and big-endian data representation by returning a byteswapped array, optionally swapped in-place. Arrays of byte-strings are not swapped. The real and imaginary parts of a complex number are swapped individually.

Parameters**inplace**

[bool, optional] If True, swap bytes in-place, default is False.

Returns**out**

[ndarray] The byteswapped array. If *inplace* is True, this is a view to self.

Examples

```
>>> import numpy as np
>>> A = np.array([1, 256, 8755], dtype=np.int16)
>>> list(map(hex, A))
['0x1', '0x100', '0x2233']
>>> A.byteswap(inplace=True)
array([ 256,      1, 13090], dtype=int16)
>>> list(map(hex, A))
['0x100', '0x1', '0x3322']
```

Arrays of byte-strings are not swapped

```
>>> A = np.array([b'ceg', b'fac'])
>>> A.byteswap()
array([b'ceg', b'fac'], dtype='<S3')
```

`A.view(A.dtype.newbyteorder()).byteswap()` produces an array with the same values but different representation in memory

```
>>> A = np.array([1, 2, 3], dtype=np.int64)
>>> A.view(np.uint8)
array([1, 0, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0, 0, 0, 0, 3, 0, 0, 0, 0, 0,
       0, 0], dtype=uint8)
>>> A.view(A.dtype.newbyteorder()).byteswap(inplace=True)
array([1, 2, 3], dtype='>i8')
>>> A.view(np.uint8)
array([0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0, 0, 0,
       0, 3], dtype=uint8)
```

method

`matrix.choose` (*choices*, *out=None*, *mode='raise'*)

Use an index array to construct a new array from a set of choices.

Refer to [numpy.choose](#) for full documentation.

See also:

[numpy.choose](#)

equivalent function

method

`matrix.clip` (*min=<no value>*, *max=<no value>*, *out=None*, ***kwargs*)

Return an array whose values are limited to `[min, max]`. One of `max` or `min` must be given.

Refer to [numpy.clip](#) for full documentation.

See also:

[numpy.clip](#)

equivalent function

method

`matrix.compress` (*condition*, *axis=None*, *out=None*)

Return selected slices of this array along given axis.

Refer to [`numpy.compress`](#) for full documentation.

See also:

[`numpy.compress`](#)
equivalent function

method

`matrix.conj` ()

Complex-conjugate all elements.

Refer to [`numpy.conjugate`](#) for full documentation.

See also:

[`numpy.conjugate`](#)
equivalent function

method

`matrix.conjugate` ()

Return the complex conjugate, element-wise.

Refer to [`numpy.conjugate`](#) for full documentation.

See also:

[`numpy.conjugate`](#)
equivalent function

method

`matrix.copy` (*order='C'*)

Return a copy of the array.

Parameters

order

[['C', 'F', 'A', 'K'], optional] Controls the memory layout of the copy. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *a* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *a* as closely as possible. (Note that this function and [`numpy.copy`](#) are very similar but have different default values for their `order=` arguments, and this function always passes sub-classes through.)

See also:

[`numpy.copy`](#)
Similar function with different default behavior
[`numpy.copyto`](#)

Notes

This function is the preferred method for creating an array copy. The function `numpy.copy` is similar, but it defaults to using order 'K', and will not pass sub-classes through by default.

Examples

```
>>> import numpy as np
>>> x = np.array([[1,2,3],[4,5,6]], order='F')
```

```
>>> y = x.copy()
```

```
>>> x.fill(0)
```

```
>>> x
array([[0, 0, 0],
       [0, 0, 0]])
```

```
>>> y
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> y.flags['C_CONTIGUOUS']
True
```

For arrays containing Python objects (e.g. `dtype=np.object_`), the copy is a shallow one. The new array will contain the same object which may lead to surprises if that object can be modified (is mutable):

```
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> b = a.copy()
>>> b[2][0] = 10
>>> a
array([1, 'm', list([10, 3, 4])], dtype=object)
```

To ensure all elements within an object array are copied, use `copy.deepcopy`:

```
>>> import copy
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> c = copy.deepcopy(a)
>>> c[2][0] = 10
>>> c
array([1, 'm', list([10, 3, 4])], dtype=object)
>>> a
array([1, 'm', list([2, 3, 4])], dtype=object)
```

method

`matrix.cumprod` (*axis=None, dtype=None, out=None*)

Return the cumulative product of the elements along the given axis.

Refer to `numpy.cumprod` for full documentation.

See also:

`numpy.cumprod`
equivalent function

method

`matrix.cumsum (axis=None, dtype=None, out=None)`

Return the cumulative sum of the elements along the given axis.

Refer to [`numpy.cumsum`](#) for full documentation.

See also:

[`numpy.cumsum`](#)

equivalent function

method

`matrix.diagonal (offset=0, axis1=0, axis2=1)`

Return specified diagonals. In NumPy 1.9 the returned array is a read-only view instead of a copy as in previous NumPy versions. In a future version the read-only restriction will be removed.

Refer to [`numpy.diagonal`](#) for full documentation.

See also:

[`numpy.diagonal`](#)

equivalent function

method

`matrix.dot (other, /, out=None)`

Refer to [`numpy.dot`](#) for full documentation.

See also:

[`numpy.dot`](#)

equivalent function

method

`matrix.dump (file)`

Dump a pickle of the array to the specified file. The array can be read back with `pickle.load` or `numpy.load`.

Parameters

file

[str or Path] A string naming the dump file.

method

`matrix.dumps ()`

Returns the pickle of the array as a string. `pickle.loads` will convert the string back to an array.

Parameters

None

method

`matrix.fill (value)`

Fill the array with a scalar value.

Parameters

value

[scalar] All elements of *a* will be assigned this value.

Examples

```
>>> import numpy as np
>>> a = np.array([1, 2])
>>> a.fill(0)
>>> a
array([0, 0])
>>> a = np.empty(2)
>>> a.fill(1)
>>> a
array([1., 1.])
```

Fill expects a scalar value and always behaves the same as assigning to a single array element. The following is a rare example where this distinction is important:

```
>>> a = np.array([None, None], dtype=np.object_)
>>> a[0] = np.array(3)
>>> a
array([array(3), None], dtype=object)
>>> a.fill(np.array(3))
>>> a
array([array(3), array(3)], dtype=object)
```

Where other forms of assignments will unpack the array being assigned:

```
>>> a[...] = np.array(3)
>>> a
array([3, 3], dtype=object)
```

method

`matrix.flatten(order='C')`

Return a flattened copy of the matrix.

All *N* elements of the matrix are placed into a single row.

Parameters**order**

[[‘C’, ‘F’, ‘A’, ‘K’], optional] ‘C’ means to flatten in row-major (C-style) order. ‘F’ means to flatten in column-major (Fortran-style) order. ‘A’ means to flatten in column-major order if *m* is Fortran *contiguous* in memory, row-major order otherwise. ‘K’ means to flatten *m* in the order the elements occur in memory. The default is ‘C’.

Returns**y**

[matrix] A copy of the matrix, flattened to a $(1, N)$ matrix where *N* is the number of elements in the original matrix.

See also:

[*ravel*](#)

Return a flattened array.

flat

A 1-D flat iterator over the matrix.

Examples

```
>>> m = np.matrix([[1,2], [3,4]])
>>> m.flatten()
matrix([[1, 2, 3, 4]])
>>> m.flatten('F')
matrix([[1, 3, 2, 4]])
```

method

`matrix.getA()`

Return *self* as an *ndarray* object.

Equivalent to `np.asarray(self)`.

Parameters

None

Returns

ret

[*ndarray*] *self* as an *ndarray*

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3,4))); x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> x.getA()
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11]])
```

method

`matrix.getA1()`

Return *self* as a flattened *ndarray*.

Equivalent to `np.asarray(x).ravel()`

Parameters

None

Returns

ret

[*ndarray*] *self*, 1-D, as an *ndarray*

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3,4))); x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> x.getA1()
array([ 0,  1,  2, ...,  9, 10, 11])
```

method

`matrix.getH()`

Returns the (complex) conjugate transpose of *self*.

Equivalent to `np.transpose(self)` if *self* is real-valued.

Parameters

None

Returns

ret

[matrix object] complex conjugate transpose of *self*

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3,4)))
>>> z = x - 1j*x; z
matrix([[ 0.+0.j,  1.-1.j,  2.-2.j,  3.-3.j],
        [ 4.-4.j,  5.-5.j,  6.-6.j,  7.-7.j],
        [ 8.-8.j,  9.-9.j, 10.-10.j, 11.-11.j]])
>>> z.getH()
matrix([[ 0.-0.j,  4.+4.j,  8.+8.j],
        [ 1.+1.j,  5.+5.j,  9.+9.j],
        [ 2.+2.j,  6.+6.j, 10.+10.j],
        [ 3.+3.j,  7.+7.j, 11.+11.j]])
```

method

`matrix.getI()`

Returns the (multiplicative) inverse of invertible *self*.

Parameters

None

Returns

ret

[matrix object] If *self* is non-singular, *ret* is such that `ret * self == self * ret == np.matrix(np.eye(self[0,:].size))` all return True.

Raises

numpy.linalg.LinAlgError: Singular matrix

If *self* is singular.

See also:

[`linalg.inv`](#)

Examples

```
>>> m = np.matrix('[1, 2; 3, 4]'); m
matrix([[1, 2],
        [3, 4]])
>>> m.getI()
matrix([[ -2. ,  1. ],
        [ 1.5, -0.5]])
>>> m.getI() * m
matrix([[ 1.,  0.], # may vary
        [ 0.,  1.]])
```

method

`matrix.getT()`

Returns the transpose of the matrix.

Does *not* conjugate! For the complex conjugate transpose, use `.H`.

Parameters

None

Returns

ret

[matrix object] The (non-conjugated) transpose of the matrix.

See also:

[*transpose*](#), [*getH*](#)

Examples

```
>>> m = np.matrix('[1, 2; 3, 4]')
>>> m
matrix([[1, 2],
        [3, 4]])
>>> m.getT()
matrix([[1, 3],
        [2, 4]])
```

method

`matrix.getfield(dtype, offset=0)`

Returns a field of the given array as a certain type.

A field is a view of the array data with a given data-type. The values in the view are determined by the given type and the offset into the current array in bytes. The offset needs to be such that the view dtype fits in the array dtype; for example an array of dtype `complex128` has 16-byte elements. If taking a view with a 32-bit integer (4 bytes), the offset needs to be between 0 and 12 bytes.

Parameters

dtype

[str or dtype] The data type of the view. The dtype size of the view can not be larger than that of the array itself.

offset

[int] Number of bytes to skip before beginning the element view.

Examples

```
>>> import numpy as np
>>> x = np.diag([1.+1.j]*2)
>>> x[1, 1] = 2 + 4.j
>>> x
array([[1.+1.j,  0.+0.j],
       [0.+0.j,  2.+4.j]])
>>> x.getfield(np.float64)
array([[1.,  0.],
       [0.,  2.]])
```

By choosing an offset of 8 bytes we can select the complex part of the array for our view:

```
>>> x.getfield(np.float64, offset=8)
array([[1.,  0.],
       [0.,  4.]])
```

method

`matrix.item(*args)`

Copy an element of an array to a standard Python scalar and return it.

Parameters***args**

[Arguments (variable number and type)]

- none: in this case, the method only works for arrays with one element (*a.size == 1*), which element is copied into a standard Python scalar object and returned.
- int_type: this argument is interpreted as a flat index into the array, specifying which element to copy and return.
- tuple of int_types: functions as does a single int_type argument, except that the argument is interpreted as an nd-index into the array.

Returns**z**

[Standard Python scalar object] A copy of the specified element of the array as a suitable Python scalar

Notes

When the data type of *a* is longdouble or clongdouble, `item()` returns a scalar array object because there is no available Python scalar that would not lose information. Void arrays return a buffer object for `item()`, unless fields are defined, in which case a tuple is returned.

`item` is very similar to `a[args]`, except, instead of an array scalar, a standard Python scalar is returned. This can be useful for speeding up access to elements of the array and doing arithmetic on elements of the array using Python's optimized math.

Examples

```
>>> import numpy as np
>>> np.random.seed(123)
>>> x = np.random.randint(9, size=(3, 3))
>>> x
array([[2, 2, 6],
       [1, 3, 6],
       [1, 0, 1]])
>>> x.item(3)
1
>>> x.item(7)
0
>>> x.item((0, 1))
2
>>> x.item((2, 2))
1
```

For an array with object dtype, elements are returned as-is.

```
>>> a = np.array([np.int64(1)], dtype=np.object_)
>>> a.item() #return np.int64
np.int64(1)
```

method

`matrix.max` (*axis=None, out=None*)

Return the maximum value along an axis.

Parameters

See ``amax`` for complete descriptions

See also:

[`amax`](#), [`ndarray.max`](#)

Notes

This is the same as `ndarray.max`, but returns a `matrix` object where `ndarray.max` would return an `ndarray`.

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3,4))); x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> x.max()
11
>>> x.max(0)
matrix([[ 8,  9, 10, 11]])
>>> x.max(1)
matrix([[ 3],
        [ 7],
        [11]])
```

method

`matrix.mean` (*axis=None, dtype=None, out=None*)

Returns the average of the matrix elements along the given axis.

Refer to `numpy.mean` for full documentation.

See also:

`numpy.mean`

Notes

Same as `ndarray.mean` except that, where that returns an `ndarray`, this returns a `matrix` object.

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3, 4)))
>>> x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> x.mean()
5.5
>>> x.mean(0)
matrix([[4., 5., 6., 7.]])
>>> x.mean(1)
matrix([[ 1.5],
        [ 5.5],
        [ 9.5]])
```

method

`matrix.min` (*axis=None, out=None*)

Return the minimum value along an axis.

Parameters

See ``amin`` for complete descriptions.

See also:

`amin`, `ndarray.min`

Notes

This is the same as `ndarray.min`, but returns a `matrix` object where `ndarray.min` would return an `ndarray`.

Examples

```
>>> x = -np.matrix(np.arange(12).reshape((3,4))); x
matrix([[ 0, -1, -2, -3],
        [-4, -5, -6, -7],
        [-8, -9, -10, -11]])
>>> x.min()
-11
>>> x.min(0)
matrix([[ -8,  -9, -10, -11]])
>>> x.min(1)
matrix([[ -3],
        [-7],
        [-11]])
```

method

`matrix.nonzero()`

Return the indices of the elements that are non-zero.

Refer to [*numpy.nonzero*](#) for full documentation.

See also:

[*numpy.nonzero*](#)
equivalent function

method

`matrix.partition(kth, axis=-1, kind='introselect', order=None)`

Partially sorts the elements in the array in such a way that the value of the element in k-th position is in the position it would be in a sorted array. In the output array, all elements smaller than the k-th element are located to the left of this element and all equal or greater are located to its right. The ordering of the elements in the two partitions on the either side of the k-th element in the output array is undefined.

Parameters

kth

[int or sequence of ints] Element index to partition by. The kth element value will be in its final sorted position and all smaller elements will be moved before it and all equal or greater elements behind it. The order of all elements in the partitions is undefined. If provided with a sequence of kth it will partition all elements indexed by kth of them into their sorted position at once.

Deprecated since version 1.22.0: Passing booleans as index is deprecated.

axis

[int, optional] Axis along which to sort. Default is -1, which means sort along the last axis.

kind

[{'introselect'}, optional] Selection algorithm. Default is 'introselect'.

order

[str or list of str, optional] When *a* is an array with fields defined, this argument specifies which fields to compare first, second, etc. A single field can be specified as a string, and not all fields need to be specified, but unspecified fields will still be used, in the order in which they come up in the dtype, to break ties.

See also:

`numpy.partition`

Return a partitioned copy of an array.

`argspartition`

Indirect partition.

`sort`

Full sort.

Notes

See `np.partition` for notes on the different algorithms.

Examples

```
>>> import numpy as np
>>> a = np.array([3, 4, 2, 1])
>>> a.partition(3)
>>> a
array([2, 1, 3, 4]) # may vary
```

```
>>> a.partition((1, 3))
>>> a
array([1, 2, 3, 4])
```

method

`matrix.prod` (*axis=None, dtype=None, out=None*)

Return the product of the array elements over the given axis.

Refer to [`prod`](#) for full documentation.

See also:

[`prod`](#), [`ndarray.prod`](#)

Notes

Same as [`ndarray.prod`](#), except, where that returns an [`ndarray`](#), this returns a [`matrix`](#) object instead.

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3,4))); x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> x.prod()
0
>>> x.prod(0)
matrix([[ 0, 45, 120, 231]])
>>> x.prod(1)
matrix([[ 0,
         [ 840],
         [7920]])
```

method

`matrix.ptp` (*axis=None, out=None*)

Peak-to-peak (maximum - minimum) value along the given axis.

Refer to [`numpy.ptp`](#) for full documentation.

See also:

[`numpy.ptp`](#)

Notes

Same as `ndarray.ptp`, except, where that would return an `ndarray` object, this returns a `matrix` object.

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3,4))); x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> x.ptp()
11
>>> x.ptp(0)
matrix([[8, 8, 8, 8]])
>>> x.ptp(1)
matrix([[3],
        [3],
        [3]])
```

method

`matrix.put` (*indices, values, mode='raise'*)

Set `a.flat[n] = values[n]` for all `n` in `indices`.

Refer to [`numpy.put`](#) for full documentation.

See also:

[`numpy.put`](#)

equivalent function

method

`matrix.ravel` (*order='C'*)

Return a flattened matrix.

Refer to [`numpy.ravel`](#) for more documentation.

Parameters

order

[{'C', 'F', 'A', 'K'}, optional] The elements of *m* are read using this index order. 'C' means to index the elements in C-like order, with the last axis index changing fastest, back to the first axis index changing slowest. 'F' means to index the elements in Fortran-like index order, with the first index changing fastest, and the last index changing slowest. Note that the 'C' and 'F' options take no account of the memory layout of the underlying array, and only refer

to the order of axis indexing. ‘A’ means to read the elements in Fortran-like index order if *m* is Fortran *contiguous* in memory, C-like order otherwise. ‘K’ means to read the elements in the order they occur in memory, except for reversing the data when strides are negative. By default, ‘C’ index order is used.

Returns

ret

[matrix] Return the matrix flattened to shape (I, N) where N is the number of elements in the original matrix. A copy is made only if necessary.

See also:

[`matrix.flatten`](#)

returns a similar output matrix but always a copy

matrix.flat

a flat iterator on the array.

[`numpy.ravel`](#)

related function which returns an ndarray

method

matrix.repeat (*repeats, axis=None*)

Repeat elements of an array.

Refer to [`numpy.repeat`](#) for full documentation.

See also:

[`numpy.repeat`](#)

equivalent function

method

matrix.reshape (*shape, /, *, order='C', copy=None*) *a.reshape(*shape, order='C', copy=None)*

matrix.reshape (**shape, order='C', copy=None*) → [`None`](#)

Returns an array containing the same data with a new shape.

Refer to [`numpy.reshape`](#) for full documentation.

See also:

[`numpy.reshape`](#)

equivalent function

Notes

Unlike the free function [`numpy.reshape`](#), this method on [`ndarray`](#) allows the elements of the shape parameter to be passed in as separate arguments. For example, `a.reshape(4, 2)` is equivalent to `a.reshape((4, 2))`.

method

matrix.resize (*new_shape, /, *, refcheck=True*) *a.resize(*new_shape, refcheck=True)*

`matrix.resize(*new_shape, refcheck=True) → None`

Change shape and size of array in-place.

Parameters

new_shape

[tuple of ints, or *n* ints] Shape of resized array.

refcheck

[bool, optional] If False, reference count will not be checked. Default is True. See Notes below for more explanation.

Returns

None

Raises

ValueError

If *a* does not own its own data or references or views to may exist.

See also:

resize

Return a new array with the specified shape.

Notes

This reallocates space for the data area if necessary.

Only contiguous arrays (data elements consecutive in memory) can be resized.

Reallocating arrays in-place can often lead to memory fragmentation and should be avoided. If the goal is to reclaim over-allocated memory, alternatives are to create a view or a copy of just the desired data, or using two passes to build the array: one to cheaply determine the shape and another to allocate and fill. Benchmark your use case to determine what is optimum. You may be surprised to find `resize` actually slows down or bloats your application.

The purpose of the reference count check is to make sure you do not use this array as a buffer for another Python object and then reallocate the memory.

On Python 3.13 and older, the check allows objects with exactly one reference to be reallocated in-place. On Python 3.14 and newer, the array must be uniquely referenced. See [1] for more details.

If you are sure that you have not shared the memory for this array with another Python object, then you may safely set `refcheck` to False.

References

[1]

Examples

Shrinking an array: array is flattened (in the order that the data are stored in memory), resized, and reshaped:

```
>>> import numpy as np
```

```
>>> a = np.array([[0, 1], [2, 3]], order='C')
>>> a.resize((2, 1))
>>> a
array([[0],
       [1]])
```

```
>>> a = np.array([[0, 1], [2, 3]], order='F')
>>> a.resize((2, 1))
>>> a
array([[0],
       [2]])
```

Enlarging an array: as above, but missing entries are filled with zeros:

```
>>> b = np.array([[0, 1], [2, 3]])
>>> b.resize(2, 3) # new_shape parameter doesn't have to be a tuple
>>> b
array([[0, 1, 2],
       [3, 0, 0]])
```

Referencing an array prevents resizing...

```
>>> c = a
>>> a.resize((1, 1))
Traceback (most recent call last):
...
ValueError: cannot resize an array that references or is referenced ...
```

Unless *refcheck* is False:

```
>>> a.resize((1, 1), refcheck=False)
>>> a
array([[0]])
>>> c
array([[0]])
```

method

`matrix.round(decimals=0, out=None)`

Return *a* with each element rounded to the given number of decimals.

Refer to [*numpy.around*](#) for full documentation.

See also:

[*numpy.around*](#)
equivalent function

method

`matrix.searchsorted(v, side='left', sorter=None)`

Find indices where elements of `v` should be inserted in `a` to maintain order.

For full documentation, see [`numpy.searchsorted`](#).

See also:

[`numpy.searchsorted`](#)
equivalent function

method

`matrix.setfield(val, dtype, offset=0)`

Put a value into a specified place in a field defined by a data-type.

Place `val` into `a`'s field defined by `dtype` and beginning `offset` bytes into the field.

Parameters

val
[object] Value to be placed in field.

dtype
[dtype object] Data-type of the field in which to place `val`.

offset
[int, optional] The number of bytes into the field at which to place `val`.

Returns

None

See also:

[`getfield`](#)

Examples

```
>>> import numpy as np
>>> x = np.eye(3)
>>> x.getfield(np.float64)
array([[1.,  0.,  0.],
       [0.,  1.,  0.],
       [0.,  0.,  1.]])
>>> x.setfield(3, np.int32)
>>> x.getfield(np.int32)
array([[3, 3, 3],
       [3, 3, 3],
       [3, 3, 3]], dtype=int32)
>>> x
array([[1.0e+000, 1.5e-323, 1.5e-323],
       [1.5e-323, 1.0e+000, 1.5e-323],
       [1.5e-323, 1.5e-323, 1.0e+000]])
>>> x.setfield(np.eye(3), np.int32)
>>> x
array([[1.,  0.,  0.],
       [0.,  1.,  0.],
       [0.,  0.,  1.]])
```

method

`matrix.setflags (write=None, align=None, uic=None)`

Set array flags WRITEABLE, ALIGNED, WRITEBACKIFCOPY, respectively.

These Boolean-valued flags affect how numpy interprets the memory area used by *a* (see Notes below). The ALIGNED flag can only be set to True if the data is actually aligned according to the type. The WRITEBACKIFCOPY flag can never be set to True. The flag WRITEABLE can only be set to True if the array owns its own memory, or the ultimate owner of the memory exposes a writeable buffer interface, or is a string. (The exception for string is made so that unpickling can be done without copying memory.)

Parameters

write

[bool, optional] Describes whether or not *a* can be written to.

align

[bool, optional] Describes whether or not *a* is aligned properly for its type.

uic

[bool, optional] Describes whether or not *a* is a copy of another “base” array.

Notes

Array flags provide information about how the memory area used for the array is to be interpreted. There are 7 Boolean flags in use, only three of which can be changed by the user: WRITEBACKIFCOPY, WRITEABLE, and ALIGNED.

WRITEABLE (W) the data area can be written to;

ALIGNED (A) the data and strides are aligned appropriately for the hardware (as determined by the compiler);

WRITEBACKIFCOPY (X) this array is a copy of some other array (referenced by `.base`). When the C-API function `PyArray_ResolveWritebackIfCopy` is called, the base array will be updated with the contents of this array.

All flags can be accessed using the single (upper case) letter as well as the full name.

Examples

```
>>> import numpy as np
>>> y = np.array([[3, 1, 7],
...              [2, 0, 0],
...              [8, 5, 9]])
>>> y
array([[3, 1, 7],
       [2, 0, 0],
       [8, 5, 9]])
>>> y.flags
C_CONTIGUOUS : True
F_CONTIGUOUS : False
OWNDATA : True
WRITEABLE : True
ALIGNED : True
WRITEBACKIFCOPY : False
>>> y.setflags(write=0, align=0)
>>> y.flags
C_CONTIGUOUS : True
```

(continues on next page)

(continued from previous page)

```

F_CONTIGUOUS : False
OWNDATA : True
WRITEABLE : False
ALIGNED : False
WRITEBACKIFCOPY : False
>>> y.setflags(uic=1)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: cannot set WRITEBACKIFCOPY flag to True

```

method

`matrix.sort(axis=-1, kind=None, order=None, *, stable=None, descending=None)`

Sort an array in-place. Refer to [numpy.sort](#) for full documentation.

Parameters

axis

[int, optional] Axis along which to sort. Default is -1, which means sort along the last axis.

kind

[[‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’], optional] Sorting algorithm. The default is ‘quicksort’. Note that both ‘stable’ and ‘mergesort’ use timsort under the covers and, in general, the actual implementation will vary with datatype. The ‘mergesort’ option is retained for backwards compatibility.

order

[str or list of str, optional] When *a* is an array with fields defined, this argument specifies which fields to compare first, second, etc. A single field can be specified as a string, and not all fields need be specified, but unspecified fields will still be used, in the order in which they come up in the dtype, to break ties.

stable

[bool, optional] Sort stability. If `True`, the returned array will maintain the relative order of a values which compare as equal. If `False` or `None`, this is not guaranteed. Internally, this option selects `kind='stable'`. Default: `None`.

New in version 2.0.0.

See also:

[numpy.sort](#)

Return a sorted copy of an array.

[numpy.argsort](#)

Indirect sort.

[numpy.lexsort](#)

Indirect stable sort on multiple keys.

[numpy.searchsorted](#)

Find elements in sorted array.

[numpy.partition](#)

Partial sort.

Notes

See `numpy.sort` for notes on the different sorting algorithms.

Examples

```
>>> import numpy as np
>>> a = np.array([[1,4], [3,1]])
>>> a.sort(axis=1)
>>> a
array([[1, 4],
       [1, 3]])
>>> a.sort(axis=0)
>>> a
array([[1, 3],
       [1, 4]])
```

Use the `order` keyword to specify a field to use when sorting a structured array:

```
>>> a = np.array([('a', 2), ('c', 1)], dtype=[('x', 'S1'), ('y', int)])
>>> a.sort(order='y')
>>> a
array([(b'c', 1), (b'a', 2)],
      dtype=[('x', 'S1'), ('y', '<i8')])
```

method

`matrix.squeeze` (*axis=None*)

Return a possibly reshaped matrix.

Refer to `numpy.squeeze` for more documentation.

Parameters

axis

[None or int or tuple of ints, optional] Selects a subset of the axes of length one in the shape. If an axis is selected with shape entry greater than one, an error is raised.

Returns

squeezed

[matrix] The matrix, but as a (1, N) matrix if it had shape (N, 1).

See also:

`numpy.squeeze`
related function

Notes

If m has a single column then that column is returned as the single row of a matrix. Otherwise m is returned. The returned matrix is always either m itself or a view into m . Supplying an axis keyword argument will not affect the returned matrix but it may cause an error to be raised.

Examples

```
>>> c = np.matrix([[1], [2]])
>>> c
matrix([[1],
        [2]])
>>> c.squeeze()
matrix([[1, 2]])
>>> r = c.T
>>> r
matrix([[1, 2]])
>>> r.squeeze()
matrix([[1, 2]])
>>> m = np.matrix([[1, 2], [3, 4]])
>>> m.squeeze()
matrix([[1, 2],
        [3, 4]])
```

method

`matrix.std` (*axis=None, dtype=None, out=None, ddof=0*)

Return the standard deviation of the array elements along the given axis.

Refer to [`numpy.std`](#) for full documentation.

See also:

[`numpy.std`](#)

Notes

This is the same as [`ndarray.std`](#), except that where an [`ndarray`](#) would be returned, a [`matrix`](#) object is returned instead.

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3, 4)))
>>> x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> x.std()
3.4520525295346629 # may vary
>>> x.std(0)
matrix([[ 3.26598632,  3.26598632,  3.26598632,  3.26598632]]) # may vary
>>> x.std(1)
matrix([[ 1.11803399],
```

(continues on next page)

(continued from previous page)

```
[ 1.11803399],
 [ 1.11803399]])
```

method

`matrix.sum(axis=None, dtype=None, out=None)`

Returns the sum of the matrix elements, along the given axis.

Refer to [numpy.sum](#) for full documentation.

See also:

[numpy.sum](#)

Notes

This is the same as [ndarray.sum](#), except that where an [ndarray](#) would be returned, a [matrix](#) object is returned instead.

Examples

```
>>> x = np.matrix([[1, 2], [4, 3]])
>>> x.sum()
10
>>> x.sum(axis=1)
matrix([[3],
        [7]])
>>> x.sum(axis=1, dtype=np.float64)
matrix([[3.],
        [7.]])
>>> out = np.zeros((2, 1), dtype=np.float64)
>>> x.sum(axis=1, dtype=np.float64, out=np.asmatrix(out))
matrix([[3.],
        [7.]])
```

method

`matrix.swapaxes(axis1, axis2, /)`

Return a view of the array with *axis1* and *axis2* interchanged.

Refer to [numpy.swapaxes](#) for full documentation.

See also:

[numpy.swapaxes](#)
equivalent function

method

`matrix.take(indices, axis=None, out=None, mode='raise')`

Return an array formed from the elements of *a* at the given indices.

Refer to [numpy.take](#) for full documentation.

See also:

numpy.take

equivalent function

method

`matrix.to_device(device, /, *, stream=None)`

For Array API compatibility. Since NumPy only supports CPU arrays, this method is a no-op that returns the same array.

Parameters

device

["cpu"] Must be "cpu".

stream

[None, optional] Currently unsupported.

Returns

out

[Self] Returns the same array.

method

`matrix.tobytes(order='C')`

Construct Python bytes containing the raw data bytes in the array.

Constructs Python bytes showing a copy of the raw contents of data memory. The bytes object is produced in C-order by default. This behavior is controlled by the `order` parameter.

Parameters

order

['C', 'F', 'A'], optional] Controls the memory layout of the bytes object. 'C' means C-order, 'F' means F-order, 'A' (short for *Any*) means 'F' if *a* is Fortran contiguous, 'C' otherwise. Default is 'C'.

Returns

s

[bytes] Python bytes exhibiting a copy of *a*'s raw data.

See also:

frombuffer

Inverse of this operation, construct a 1-dimensional array from Python bytes.

Examples

```
>>> import numpy as np
>>> x = np.array([[0, 1], [2, 3]], dtype='<u2')
>>> x.tobytes()
b'\x00\x00\x01\x00\x02\x00\x03\x00'
>>> x.tobytes('C') == x.tobytes()
True
>>> x.tobytes('F')
b'\x00\x00\x02\x00\x01\x00\x03\x00'
```

method

```
matrix.tofile(fid, /, sep=",", format='%s')
```

Write array to a file as text or binary (default).

Data is always written in 'C' order, independent of the order of *a*. The data produced by this method can be recovered using the function `fromfile()`.

Parameters

fid

[file or str or Path] An open file object, or a string containing a filename.

sep

[str] Separator between array items for text output. If "" (empty), a binary file is written, equivalent to `file.write(a.tobytes())`.

format

[str] Format string for text file output. Each entry in the array is formatted to text by first converting it to the closest Python type, and then using "format" % item.

Notes

This is a convenience function for quick storage of array data. Information on endianness and precision is lost, so this method is not a good choice for files intended to archive data or transport data between machines with different endianness. Some of these problems can be overcome by outputting the data as text files, at the expense of speed and file size.

When `fid` is a file object, array contents are directly written to the file, bypassing the file object's `write` method. As a result, `tofile` cannot be used with files objects supporting compression (e.g., `GzipFile`) or file-like objects that do not support `fileno()` (e.g., `BytesIO`).

method

```
matrix.tolist()
```

Return the matrix as a (possibly nested) list.

See `ndarray.tolist` for full documentation.

See also:

`ndarray.tolist`

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3,4))); x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> x.tolist()
[[0, 1, 2, 3], [4, 5, 6, 7], [8, 9, 10, 11]]
```

method

```
matrix.trace(offset=0, axis1=0, axis2=1, dtype=None, out=None)
```

Return the sum along diagonals of the array.

Refer to `numpy.trace` for full documentation.

See also:

`numpy.trace`

equivalent function

method

`matrix.transpose(*axes)`

Returns a view of the array with axes transposed.

Refer to `numpy.transpose` for full documentation.

Parameters

axes

[None, tuple of ints, or n ints]

- None or no argument: reverses the order of the axes.
- tuple of ints: i in the j -th place in the tuple means that the array's i -th axis becomes the transposed array's j -th axis.
- n ints: same as an n -tuple of the same ints (this form is intended simply as a “convenience” alternative to the tuple form).

Returns

p

[ndarray] View of the array with its axes suitably permuted.

See also:

`transpose`

Equivalent function.

`ndarray.T`

Array property returning the array transposed.

`ndarray.reshape`

Return a reshaped ndarray without changing data.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> a
array([[1, 2],
       [3, 4]])
>>> a.transpose()
array([[1, 3],
       [2, 4]])
>>> a.transpose((1, 0))
array([[1, 3],
       [2, 4]])
>>> a.transpose(1, 0)
array([[1, 3],
       [2, 4]])
```

```
>>> a = np.array([1, 2, 3, 4])
>>> a
array([1, 2, 3, 4])
```

(continues on next page)

(continued from previous page)

```
>>> a.transpose()
array([1, 2, 3, 4])
```

method

`matrix.var` (*axis=None, dtype=None, out=None, ddof=0*)

Returns the variance of the matrix elements, along the given axis.

Refer to [numpy.var](#) for full documentation.

See also:

[numpy.var](#)

Notes

This is the same as [ndarray.var](#), except that where an [ndarray](#) would be returned, a [matrix](#) object is returned instead.

Examples

```
>>> x = np.matrix(np.arange(12).reshape((3, 4)))
>>> x
matrix([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]])
>>> x.var()
11.916666666666666
>>> x.var(0)
matrix([[ 10.66666667,  10.66666667,  10.66666667,  10.66666667]]) # may vary
>>> x.var(1)
matrix([[ 1.25],
        [ 1.25],
        [ 1.25]])
```

method

`matrix.view` (*[dtype][, type]*)

New view of array with the same data.

Note: Passing `None` for `dtype` is different from omitting the parameter, since the former invokes `dtype(None)` which is an alias for `dtype(np.float64)`.

Parameters

`dtype`

[data-type or ndarray sub-class, optional] Data-type descriptor of the returned view, e.g., `float32` or `int16`. Omitting it results in the view having the same data-type as *a*. This argument can also be specified as an ndarray sub-class, which then specifies the type of the returned object (this is equivalent to setting the `type` parameter).

type

[Python type, optional] Type of the returned view, e.g., ndarray or matrix. Again, omission of the parameter results in type preservation.

Notes

`a.view()` is used two different ways:

`a.view(some_dtype)` or `a.view(dtype=some_dtype)` constructs a view of the array's memory with a different data-type. This can cause a reinterpretation of the bytes of memory.

`a.view(ndarray_subclass)` or `a.view(type=ndarray_subclass)` just returns an instance of `ndarray_subclass` that looks at the same array (same shape, dtype, etc.) This does not cause a reinterpretation of the memory.

For `a.view(some_dtype)`, if `some_dtype` has a different number of bytes per entry than the previous dtype (for example, converting a regular array to a structured array), then the last axis of `a` must be contiguous. This axis will be resized in the result.

Changed in version 1.23.0: Only the last axis needs to be contiguous. Previously, the entire array had to be C-contiguous.

Examples

```
>>> import numpy as np
>>> x = np.array([-1, 2], dtype=[('a', np.int8), ('b', np.int8)])
```

Viewing array data using a different type and dtype:

```
>>> nonneg = np.dtype([("a", np.uint8), ("b", np.uint8)])
>>> y = x.view(dtype=nonneg, type=np.recarray)
>>> x["a"]
array([-1], dtype=int8)
>>> y.a
array([255], dtype=uint8)
```

Creating a view on a structured array so it can be used in calculations

```
>>> x = np.array([(1, 2), (3, 4)], dtype=[('a', np.int8), ('b', np.int8)])
>>> xv = x.view(dtype=np.int8).reshape(-1, 2)
>>> xv
array([[1, 2],
       [3, 4]], dtype=int8)
>>> xv.mean(0)
array([2., 3.])
```

Making changes to the view changes the underlying array

```
>>> xv[0, 1] = 20
>>> x
array([(1, 20), (3, 4)], dtype=[('a', 'i1'), ('b', 'i1')])
```

Using a view to convert an array to a recarray:

```
>>> z = x.view(np.recarray)
>>> z.a
array([1, 3], dtype=int8)
```

Views share data:

```
>>> x[0] = (9, 10)
>>> z[0]
np.record((9, 10), dtype=[('a', 'i1'), ('b', 'i1')])
```

Views that change the dtype size (bytes per entry) should normally be avoided on arrays defined by slices, transposes, fortran-ordering, etc.:

```
>>> x = np.array([[1, 2, 3], [4, 5, 6]], dtype=np.int16)
>>> y = x[:, ::2]
>>> y
array([[1, 3],
       [4, 6]], dtype=int16)
>>> y.view(dtype=[('width', np.int16), ('length', np.int16)])
Traceback (most recent call last):
...
ValueError: To change to a dtype of a different size, the last axis must be_
↳ contiguous
>>> z = y.copy()
>>> z.view(dtype=[('width', np.int16), ('length', np.int16)])
array([[1, 3],
       [4, 6]], dtype=[('width', '<i2'), ('length', '<i2')])
```

However, views that change dtype are totally fine for arrays with a contiguous last axis, even if the rest of the axes are not C-contiguous:

```
>>> x = np.arange(2 * 3 * 4, dtype=np.int8).reshape(2, 3, 4)
>>> x.transpose(1, 0, 2).view(np.int16)
array([[[ 256,  770],
        [3340, 3854]],

       [[1284, 1798],
        [4368, 4882]],

       [[2312, 2826],
        [5396, 5910]]], dtype=int16)
```

See also:

[array](#)

Examples

```
>>> import numpy as np
>>> a = np.matrix('1 2; 3 4')
>>> a
matrix([[1, 2],
        [3, 4]])
```

```
>>> np.matrix([[1, 2], [3, 4]])
matrix([[1, 2],
        [3, 4]])
```

`numpy.asmatrix(data, dtype=None)`

Interpret the input as a matrix.

Unlike *matrix*, *asmatrix* does not make a copy if the input is already a matrix or an ndarray. Equivalent to `matrix(data, copy=False)`.

Parameters

data

[array_like] Input data.

dtype

[data-type] Data-type of the output matrix.

Returns

mat

[matrix] *data* interpreted as a matrix.

Examples

```
>>> import numpy as np
>>> x = np.array([[1, 2], [3, 4]])
```

```
>>> m = np.asmatrix(x)
```

```
>>> x[0,0] = 5
```

```
>>> m
matrix([[5, 2],
        [3, 4]])
```

`numpy.bmat(obj, ldict=None, gdict=None)`

Build a matrix object from a string, nested sequence, or array.

Parameters

obj

[str or array_like] Input data. If a string, variables in the current scope may be referenced by name.

ldict

[dict, optional] A dictionary that replaces local operands in current frame. Ignored if *obj* is not a string or *gdict* is None.

gdict

[dict, optional] A dictionary that replaces global operands in current frame. Ignored if *obj* is not a string.

Returns**out**

[matrix] Returns a matrix object, which is a specialized 2-D array.

See also:***block***

A generalization of this function for N-d arrays, that returns normal ndarrays.

Examples

```
>>> import numpy as np
>>> A = np.asmatrix('1 1; 1 1')
>>> B = np.asmatrix('2 2; 2 2')
>>> C = np.asmatrix('3 4; 5 6')
>>> D = np.asmatrix('7 8; 9 0')
```

All the following expressions construct the same block matrix:

```
>>> np.bmat([[A, B], [C, D]])
matrix([[1, 1, 2, 2],
        [1, 1, 2, 2],
        [3, 4, 7, 8],
        [5, 6, 9, 0]])
>>> np.bmat(np.r_[np.c_[A, B], np.c_[C, D]])
matrix([[1, 1, 2, 2],
        [1, 1, 2, 2],
        [3, 4, 7, 8],
        [5, 6, 9, 0]])
>>> np.bmat('A,B; C,D')
matrix([[1, 1, 2, 2],
        [1, 1, 2, 2],
        [3, 4, 7, 8],
        [5, 6, 9, 0]])
```

Example 1: Matrix creation from a string

```
>>> import numpy as np
>>> a = np.asmatrix('1 2 3; 4 5 3')
>>> print((a*a.T).I)
[[ 0.29239766 -0.13450292]
 [-0.13450292  0.08187135]]
```

Example 2: Matrix creation from a nested sequence

```
>>> import numpy as np
>>> np.asmatrix([[1,5,10],[1.0,3,4j]])
matrix([[ 1.+0.j,  5.+0.j, 10.+0.j],
        [ 1.+0.j,  3.+0.j,  0.+4.j]])
```

Example 3: Matrix creation from an array

```
>>> import numpy as np
>>> np.asmatrix(np.random.rand(3,3)).T
matrix([[4.17022005e-01, 3.02332573e-01, 1.86260211e-01],
        [7.20324493e-01, 1.46755891e-01, 3.45560727e-01],
        [1.14374817e-04, 9.23385948e-02, 3.96767474e-01]])
```

Memory-mapped file arrays

Memory-mapped files are useful for reading and/or modifying small segments of a large file with regular layout, without reading the entire file into memory. A simple subclass of the ndarray uses a memory-mapped file for the data buffer of the array. For small files, the over-head of reading the entire file into memory is typically not significant, however for large files using memory mapping can save considerable resources.

Memory-mapped-file arrays have one additional method (besides those they inherit from the ndarray): `.flush()` which must be called manually by the user to ensure that any changes to the array actually get written to disk.

<code>memmap(filename[, dtype, mode, offset, ...])</code>	Create a memory-map to an array stored in a <i>binary</i> file on disk.
<code>memmap.flush()</code>	Write any changes in the array to the file on disk.

class `numpy.memmap` (*filename, dtype=<class 'numpy.ubyte'>, mode='r+', offset=0, shape=None, order='C'*)

Create a memory-map to an array stored in a *binary* file on disk.

Memory-mapped files are used for accessing small segments of large files on disk, without reading the entire file into memory. NumPy's memmap's are array-like objects. This differs from Python's mmap module, which uses file-like objects.

This subclass of ndarray has some unpleasant interactions with some operations, because it doesn't quite fit properly as a subclass. An alternative to using this subclass is to create the mmap object yourself, then create an ndarray with ndarray.__new__ directly, passing the object created in its 'buffer=' parameter.

This class may at some point be turned into a factory function which returns a view into an mmap buffer.

Flush the memmap instance to write the changes to the file. Currently there is no API to close the underlying mmap. It is tricky to ensure the resource is actually closed, since it may be shared between different memmap instances.

Parameters

filename

[str, file-like object, or pathlib.Path instance] The file name or file object to be used as the array data buffer.

dtype

[data-type, optional] The data-type used to interpret the file contents. Default is `uint8`.

mode

[{'r+', 'r', 'w+', 'c'}, optional] The file is opened in this mode:

'r'	Open existing file for reading only.
'r+'	Open existing file for reading and writing.
'w+'	Create or overwrite existing file for reading and writing. If <code>mode == 'w+'</code> then <code>shape</code> must also be specified.
'c'	Copy-on-write: assignments affect data in memory, but changes are not saved to disk. The file on disk is read-only.

Default is 'r+'.

offset

[int, optional] In the file, array data starts at this offset. Since *offset* is measured in bytes, it should normally be a multiple of the byte-size of *dtype*. When `mode != 'r'`, even positive offsets beyond end of file are valid; The file will be extended to accommodate the additional data. By default, `memmap` will start at the beginning of the file, even if `filename` is a file pointer `fp` and `fp.tell() != 0`.

shape

[int or sequence of ints, optional] The desired shape of the array. If `mode == 'r'` and the number of remaining bytes after *offset* is not a multiple of the byte-size of *dtype*, you must specify *shape*. By default, the returned array will be 1-D with the number of elements determined by file size and data-type.

Changed in version 2.0: The shape parameter can now be any integer sequence type, previously types were limited to tuple and int.

order

[{'C', 'F'}, optional] Specify the order of the ndarray memory layout: row-major, C-style or column-major, Fortran-style. This only has an effect if the shape is greater than 1-D. The default order is 'C'.

Attributes

filename

[str or pathlib.Path instance] Path to the mapped file.

offset

[int] Offset position in the file.

mode

[str] File mode.

Methods

<i>flush()</i>	Write any changes in the array to the file on disk.
----------------	---

method

`memmap.flush()`

Write any changes in the array to the file on disk.

For further information, see [memmap](#).

Parameters

None

See also:

[memmap](#)

See also:

[lib.format.open_memmap](#)

Create or load a memory-mapped `.npy` file.

Notes

The memmap object can be used anywhere an ndarray is accepted. Given a memmap `fp`, `isinstance(fp, numpy.ndarray)` returns `True`.

Memory-mapped files cannot be larger than 2GB on 32-bit systems.

When a memmap causes a file to be created or extended beyond its current size in the filesystem, the contents of the new part are unspecified. On systems with POSIX filesystem semantics, the extended part will be filled with zero bytes.

Examples

```
>>> import numpy as np
>>> data = np.arange(12, dtype=np.float32).reshape((3, 4))
```

This example uses a temporary file so that doctest doesn't write files to your directory. You would use a 'normal' filename.

```
>>> from tempfile import mkdtemp
>>> import os.path as path
>>> filename = path.join(mkdtemp(), 'newfile.dat')
```

Create a memmap with dtype and shape that matches our data:

```
>>> fp = np.memmap(filename, dtype=np.float32, mode='w+', shape=(3,4))
>>> fp
memmap([[0., 0., 0., 0.],
        [0., 0., 0., 0.],
        [0., 0., 0., 0.]], dtype=float32)
```

Write data to memmap array:

```
>>> fp[:] = data[:]
>>> fp
memmap([[ 0.,  1.,  2.,  3.],
        [ 4.,  5.,  6.,  7.],
        [ 8.,  9., 10., 11.]], dtype=float32)
```

```
>>> fp.filename == path.abspath(filename)
True
```

Flushes memory changes to disk in order to read them back

```
>>> fp.flush()
```

Load the memmap and verify data was stored:

```
>>> newfp = np.memmap(filename, dtype=np.float32, mode='r', shape=(3,4))
>>> newfp
memmap([[ 0.,  1.,  2.,  3.],
        [ 4.,  5.,  6.,  7.],
        [ 8.,  9., 10., 11.]], dtype=float32)
```

Read-only memmap:

```
>>> fpr = np.memmap(filename, dtype=np.float32, mode='r', shape=(3,4))
>>> fpr.flags.writeable
False
```

Copy-on-write memmap:

```
>>> fpc = np.memmap(filename, dtype=np.float32, mode='c', shape=(3,4))
>>> fpc.flags.writeable
True
```

It's possible to assign to copy-on-write array, but values are only written into the memory copy of the array, and not written to disk:

```
>>> fpc
memmap([[ 0.,  1.,  2.,  3.],
         [ 4.,  5.,  6.,  7.],
         [ 8.,  9., 10., 11.]], dtype=float32)
>>> fpc[0,:] = 0
>>> fpc
memmap([[ 0.,  0.,  0.,  0.],
         [ 4.,  5.,  6.,  7.],
         [ 8.,  9., 10., 11.]], dtype=float32)
```

File on disk is unchanged:

```
>>> fpr
memmap([[ 0.,  1.,  2.,  3.],
         [ 4.,  5.,  6.,  7.],
         [ 8.,  9., 10., 11.]], dtype=float32)
```

Offset into a memmap:

```
>>> fpo = np.memmap(filename, dtype=np.float32, mode='r', offset=16)
>>> fpo
memmap([ 4.,  5.,  6.,  7.,  8.,  9., 10., 11.], dtype=float32)
```

Example:

```
>>> import numpy as np
```

```
>>> a = np.memmap('newfile.dat', dtype=np.float64, mode='w+', shape=1000)
>>> a[10] = 10.0
>>> a[30] = 30.0
>>> del a
```

```
>>> b = np.fromfile('newfile.dat', dtype=np.float64)
>>> print(b[10], b[30])
10.0 30.0
```

```
>>> a = np.memmap('newfile.dat', dtype=np.float64)
>>> print(a[10], a[30])
10.0 30.0
```

Character arrays (`numpy.char`)

See also:

Creating character arrays (`numpy.char`)

Note: The `chararray` class exists for backwards compatibility with Numarray, it is not recommended for new development. Starting from numpy 1.4, if one needs arrays of strings, it is recommended to use arrays of `dtype object_`, `bytes_` or `str_`, and use the free functions in the `numpy.char` module for fast vectorized string operations.

Deprecated since version 2.5: `numpy.char.chararray` is deprecated. Use an `ndarray` with a string or bytes dtype instead.

These are enhanced arrays of either `str_` type or `bytes_` type. These arrays inherit from the `ndarray`, but specially-define the operations `+`, `*`, and `%` on a (broadcasting) element-by-element basis. These operations are not available on the standard `ndarray` of character type. In addition, the `chararray` has all of the standard `str` (and `bytes`) methods, executing them on an element-by-element basis. Perhaps the easiest way to create a `chararray` is to use `self.view(chararray)` where `self` is an `ndarray` of `str` or unicode data-type. However, a `chararray` can also be created using the `chararray` constructor, or via the `numpy.char.array` function:

<code>char.chararray(shape[, itemsize, unicode, ...])</code>	Provides a convenient view on arrays of string and unicode values.
<code>char.array(obj[, itemsize, copy, unicode, order])</code>	Create a <code>chararray</code> .

Another difference with the standard `ndarray` of `str` data-type is that the `chararray` inherits the feature introduced by Numarray that white-space at the end of any element in the array will be ignored on item retrieval and comparison operations.

Record arrays

See also:

Creating record arrays, Data type routines, Data type objects (dtype).

NumPy provides the `recarray` class which allows accessing the fields of a structured array as attributes, and a corresponding scalar data type object `record`.

<code>recarray(shape[, dtype, buf, offset, ...])</code>	Construct an <code>ndarray</code> that allows field access using attributes.
<code>record(length_or_data, /[, dtype])</code>	A data-type scalar that allows field access as attribute lookup.

class `numpy.recarray` (*shape, dtype=None, buf=None, offset=0, strides=None, formats=None, names=None, titles=None, byteorder=None, aligned=False, order='C'*)

Construct an `ndarray` that allows field access using attributes.

Arrays may have a data-types containing fields, analogous to columns in a spread sheet. An example is `[(x, int), (y, float)]`, where each entry in the array is a pair of `(int, float)`. Normally, these attributes are accessed using dictionary lookups such as `arr['x']` and `arr['y']`. Record arrays allow the fields to be accessed as members of the array, using `arr.x` and `arr.y`.

Parameters

shape

[tuple] Shape of output array.

dtype

[data-type, optional] The desired data-type. By default, the data-type is determined from *formats*, *names*, *titles*, *aligned* and *byteorder*.

formats

[list of data-types, optional] A list containing the data-types for the different columns, e.g. `['i4', 'f8', 'i4']`. *formats* does *not* support the new convention of using types directly, i.e. `(int, float, int)`. Note that *formats* must be a list, not a tuple. Given that *formats* is somewhat limited, we recommend specifying *dtype* instead.

names

[tuple of str, optional] The name of each column, e.g. `('x', 'y', 'z')`.

buf

[buffer, optional] By default, a new array is created of the given shape and data-type. If *buf* is specified and is an object exposing the buffer interface, the array will use the memory from the existing buffer. In this case, the *offset* and *strides* keywords are available.

Attributes**T**

View of the transposed array.

base

Base object if memory is from some other object.

ctypes

An object to simplify the interaction of the array with the ctypes module.

data

Python buffer object pointing to the start of the array's data.

device**dtype**

Data-type of the array's elements.

flags

Information about the memory layout of the array.

flat

A 1-D iterator over the array.

imag

The imaginary part of the array.

itemsize

Length of one array element in bytes.

mT

View of the matrix transposed array.

nbytes

Total bytes consumed by the elements of the array.

ndim

Number of array dimensions.

real

The real part of the array.

shape

Tuple of array dimensions.

size

Number of elements in the array.

strides

Tuple of bytes to step in each dimension when traversing an array.

Methods

<i>all</i> ([axis, out, keepdims, where])	Returns True if all elements evaluate to True.
<i>any</i> ([axis, out, keepdims, where])	Returns True if any of the elements of <i>a</i> evaluate to True.
<i>argmax</i> ([axis, out, keepdims])	Return indices of the maximum values along the given axis.
<i>argmin</i> ([axis, out, keepdims])	Return indices of the minimum values along the given axis.
<i>argpartition</i> (kth[, axis, kind, order])	Returns the indices that would partition this array.
<i>argsort</i> ([axis, kind, order, stable, descending])	Returns the indices that would sort this array.
<i>astype</i> (dtype[, order, casting, subok, copy])	Copy of the array, cast to a specified type.
<i>byteswap</i> ([inplace])	Swap the bytes of the array elements
<i>choose</i> (choices[, out, mode])	Use an index array to construct a new array from a set of choices.
<i>clip</i> ([min, max, out])	Return an array whose values are limited to [min, max].
<i>compress</i> (condition[, axis, out])	Return selected slices of this array along given axis.
<i>conj</i> ()	Complex-conjugate all elements.
<i>conjugate</i> ()	Return the complex conjugate, element-wise.
<i>copy</i> ([order])	Return a copy of the array.
<i>cumprod</i> ([axis, dtype, out])	Return the cumulative product of the elements along the given axis.
<i>cumsum</i> ([axis, dtype, out])	Return the cumulative sum of the elements along the given axis.
<i>diagonal</i> ([offset, axis1, axis2])	Return specified diagonals.
<i>dot</i> (other, /[, out])	Refer to numpy.dot for full documentation.
<i>dump</i> (file)	Dump a pickle of the array to the specified file.
<i>dumps</i> ()	Returns the pickle of the array as a string.
<i>fill</i> (value)	Fill the array with a scalar value.
<i>flatten</i> ([order])	Return a copy of the array collapsed into one dimension.
<i>getfield</i> (dtype[, offset])	Returns a field of the given array as a certain type.
<i>item</i> (*args)	Copy an element of an array to a standard Python scalar and return it.
<i>max</i> ([axis, out, keepdims, initial, where])	Return the maximum along a given axis.
<i>mean</i> ([axis, dtype, out, keepdims, where])	Returns the average of the array elements along given axis.
<i>min</i> ([axis, out, keepdims, initial, where])	Return the minimum along a given axis.
<i>nonzero</i> ()	Return the indices of the elements that are non-zero.
<i>partition</i> (kth[, axis, kind, order])	Partially sorts the elements in the array in such a way that the value of the element in k-th position is in the position it would be in a sorted array.

continues on next page

Table 8 – continued from previous page

<code>prod([axis, dtype, out, keepdims, initial, ...])</code>	Return the product of the array elements over the given axis
<code>put(indices, values[, mode])</code>	Set <code>a.flat[n] = values[n]</code> for all <code>n</code> in indices.
<code>ravel([order])</code>	Return a flattened array.
<code>repeat(repeats[, axis])</code>	Repeat elements of an array.
<code>reshape(a.reshape)</code>	Returns an array containing the same data with a new shape.
<code>resize(a.resize)</code>	Change shape and size of array in-place.
<code>round([decimals, out])</code>	Return <code>a</code> with each element rounded to the given number of decimals.
<code>searchsorted(v[, side, sorter])</code>	Find indices where elements of <code>v</code> should be inserted in <code>a</code> to maintain order.
<code>setfield(val, dtype[, offset])</code>	Put a value into a specified place in a field defined by a data-type.
<code>setflags([write, align, uic])</code>	Set array flags WRITEABLE, ALIGNED, WRITEBACKIFCOPY, respectively.
<code>sort([axis, kind, order, stable, descending])</code>	Sort an array in-place.
<code>squeeze([axis])</code>	Remove axes of length one from <code>a</code> .
<code>std([axis, dtype, out, ddof, keepdims, ...])</code>	Returns the standard deviation of the array elements along given axis.
<code>sum([axis, dtype, out, keepdims, initial, where])</code>	Return the sum of the array elements over the given axis.
<code>swapaxes(axis1, axis2, /)</code>	Return a view of the array with <code>axis1</code> and <code>axis2</code> interchanged.
<code>take(indices[, axis, out, mode])</code>	Return an array formed from the elements of <code>a</code> at the given indices.
<code>to_device(device, /, *[, stream])</code>	For Array API compatibility.
<code>tobytes([order])</code>	Construct Python bytes containing the raw data bytes in the array.
<code>tofile(fid, /[, sep, format])</code>	Write array to a file as text or binary (default).
<code>tolist()</code>	Return the array as an <code>a.ndim</code> -levels deep nested list of Python scalars.
<code>trace([offset, axis1, axis2, dtype, out])</code>	Return the sum along diagonals of the array.
<code>transpose(*axes)</code>	Returns a view of the array with axes transposed.
<code>var([axis, dtype, out, ddof, keepdims, ...])</code>	Returns the variance of the array elements, along given axis.
<code>view([dtype][, type])</code>	New view of array with the same data.

method

`recarray.all (axis=None, out=None, *, keepdims=<no value>, where=<no value>)`

Returns True if all elements evaluate to True.

Refer to [numpy.all](#) for full documentation.

See also:

[numpy.all](#)

equivalent function

method

`recarray.any (axis=None, out=None, *, keepdims=<no value>, where=<no value>)`

Returns True if any of the elements of `a` evaluate to True.

Refer to [*numpy.any*](#) for full documentation.

See also:

[*numpy.any*](#)
equivalent function

method

`recarray.argmax (axis=None, out=None, *, keepdims=False)`

Return indices of the maximum values along the given axis.

Refer to [*numpy.argmax*](#) for full documentation.

See also:

[*numpy.argmax*](#)
equivalent function

method

`recarray.argmin (axis=None, out=None, *, keepdims=False)`

Return indices of the minimum values along the given axis.

Refer to [*numpy.argmin*](#) for detailed documentation.

See also:

[*numpy.argmin*](#)
equivalent function

method

`recarray.argpartition (kth, axis=-1, kind='introselect', order=None)`

Returns the indices that would partition this array.

Refer to [*numpy.argpartition*](#) for full documentation.

See also:

[*numpy.argpartition*](#)
equivalent function

method

`recarray.argsort (axis=-1, kind=None, order=None, *, stable=None, descending=None)`

Returns the indices that would sort this array.

Refer to [*numpy.argsort*](#) for full documentation.

See also:

[*numpy.argsort*](#)
equivalent function

method

`recarray.astype(dtype, order='K', casting='unsafe', subok=True, copy=True)`

Copy of the array, cast to a specified type.

Parameters

dtype

[str or dtype] Typecode or data-type to which the array is cast.

order

[[`'C'`, `'F'`, `'A'`, `'K'`], optional] Controls the memory layout order of the result. `'C'` means C order, `'F'` means Fortran order, `'A'` means `'F'` order if all the arrays are Fortran contiguous, `'C'` order otherwise, and `'K'` means as close to the order the array elements appear in memory as possible. Default is `'K'`.

casting

[[`'no'`, `'equiv'`, `'safe'`, `'same_kind'`, `'same_value'`, `'unsafe'`], optional] Controls what kind of data casting may occur. Defaults to `'unsafe'` for backwards compatibility.

- `'no'` means the data types should not be cast at all.
- `'equiv'` means only byte-order changes are allowed.
- `'safe'` means only casts which can preserve values are allowed.
- `'same_kind'` means only safe casts or casts within a kind, like float64 to float32, are allowed.
- `'unsafe'` means any data conversions may be done.
- `'same_value'` means any data conversions may be done, but the values must not change, including rounding of floats or overflow of ints

New in version 2.4: Support for `'same_value'` was added.

subok

[bool, optional] If True, then sub-classes will be passed-through (default), otherwise the returned array will be forced to be a base-class array.

copy

[bool, optional] By default, `astype` always returns a newly allocated array. If this is set to false, and the `dtype`, `order`, and `subok` requirements are satisfied, the input array is returned instead of a copy.

Returns

arr_t

[ndarray] Unless `copy` is False and the other conditions for returning the input array are satisfied (see description for `copy` input parameter), `arr_t` is a new array of the same shape as the input array, with dtype, order given by `dtype`, `order`.

Raises

ComplexWarning

When casting from complex to float or int. To avoid this, one should use `a.real.astype(t)`.

ValueError

When casting using `'same_value'` and the values change or would overflow

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 2.5])
>>> x
array([1. ,  2. ,  2.5])
```

```
>>> x.astype(np.int_)
array([1, 2, 2])
```

```
>>> x.astype(np.int_, casting="same_value")
Traceback (most recent call last):
...
ValueError: could not cast 'same_value' double to long
```

```
>>> x[:2].astype(np.int_, casting="same_value")
array([1, 2])
```

method

`recarray.byteswap(inplace=False)`

Swap the bytes of the array elements

Toggle between low-endian and big-endian data representation by returning a byteswapped array, optionally swapped in-place. Arrays of byte-strings are not swapped. The real and imaginary parts of a complex number are swapped individually.

Parameters

inplace

[bool, optional] If True, swap bytes in-place, default is False.

Returns

out

[ndarray] The byteswapped array. If *inplace* is True, this is a view to self.

Examples

```
>>> import numpy as np
>>> A = np.array([1, 256, 8755], dtype=np.int16)
>>> list(map(hex, A))
['0x1', '0x100', '0x2233']
>>> A.byteswap(inplace=True)
array([ 256,      1, 13090], dtype=int16)
>>> list(map(hex, A))
['0x100', '0x1', '0x3322']
```

Arrays of byte-strings are not swapped

```
>>> A = np.array([b'ceg', b'fac'])
>>> A.byteswap()
array([b'ceg', b'fac'], dtype='<S3')
```

`A.view(A.dtype.newbyteorder()).byteswap()` produces an array with the same values but different representation in memory

```

>>> A = np.array([1, 2, 3], dtype=np.int64)
>>> A.view(np.uint8)
array([1, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0, 0, 0, 3, 0, 0, 0, 0, 0,
       0, 0], dtype=uint8)
>>> A.view(A.dtype.newbyteorder()).byteswap(inplace=True)
array([1, 2, 3], dtype='>i8')
>>> A.view(np.uint8)
array([0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0,
       0, 3], dtype=uint8)

```

method

`recarray.choose` (*choices*, *out=None*, *mode='raise'*)

Use an index array to construct a new array from a set of choices.

Refer to [numpy.choose](#) for full documentation.

See also:

[numpy.choose](#)
equivalent function

method

`recarray.clip` (*min=<no value>*, *max=<no value>*, *out=None*, ***kwargs*)

Return an array whose values are limited to `[min, max]`. One of `max` or `min` must be given.

Refer to [numpy.clip](#) for full documentation.

See also:

[numpy.clip](#)
equivalent function

method

`recarray.compress` (*condition*, *axis=None*, *out=None*)

Return selected slices of this array along given axis.

Refer to [numpy.compress](#) for full documentation.

See also:

[numpy.compress](#)
equivalent function

method

`recarray.conj` ()

Complex-conjugate all elements.

Refer to [numpy.conjugate](#) for full documentation.

See also:

[numpy.conjugate](#)
equivalent function

method

`recarray.conjugate()`

Return the complex conjugate, element-wise.

Refer to [`numpy.conjugate`](#) for full documentation.

See also:

[`numpy.conjugate`](#)

equivalent function

method

`recarray.copy(order='C')`

Return a copy of the array.

Parameters

order

[['C', 'F', 'A', 'K'], optional] Controls the memory layout of the copy. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *a* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *a* as closely as possible. (Note that this function and [`numpy.copy`](#) are very similar but have different default values for their `order=` arguments, and this function always passes sub-classes through.)

See also:

[`numpy.copy`](#)

Similar function with different default behavior

[`numpy.copyto`](#)

Notes

This function is the preferred method for creating an array copy. The function [`numpy.copy`](#) is similar, but it defaults to using order 'K', and will not pass sub-classes through by default.

Examples

```
>>> import numpy as np
>>> x = np.array([[1,2,3],[4,5,6]], order='F')
```

```
>>> y = x.copy()
```

```
>>> x.fill(0)
```

```
>>> x
array([[0, 0, 0],
       [0, 0, 0]])
```

```
>>> y
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> y.flags['C_CONTIGUOUS']
True
```

For arrays containing Python objects (e.g. `dtype=np.object_`), the copy is a shallow one. The new array will contain the same object which may lead to surprises if that object can be modified (is mutable):

```
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> b = a.copy()
>>> b[2][0] = 10
>>> a
array([1, 'm', list([10, 3, 4])], dtype=object)
```

To ensure all elements within an object array are copied, use `copy.deepcopy`:

```
>>> import copy
>>> a = np.array([1, 'm', [2, 3, 4]], dtype=np.object_)
>>> c = copy.deepcopy(a)
>>> c[2][0] = 10
>>> c
array([1, 'm', list([10, 3, 4])], dtype=object)
>>> a
array([1, 'm', list([2, 3, 4])], dtype=object)
```

method

`recarray.cumprod` (*axis=None, dtype=None, out=None*)

Return the cumulative product of the elements along the given axis.

Refer to `numpy.cumprod` for full documentation.

See also:

`numpy.cumprod`
equivalent function

method

`recarray.cumsum` (*axis=None, dtype=None, out=None*)

Return the cumulative sum of the elements along the given axis.

Refer to `numpy.cumsum` for full documentation.

See also:

`numpy.cumsum`
equivalent function

method

`recarray.diagonal` (*offset=0, axis1=0, axis2=1*)

Return specified diagonals. In NumPy 1.9 the returned array is a read-only view instead of a copy as in previous NumPy versions. In a future version the read-only restriction will be removed.

Refer to `numpy.diagonal` for full documentation.

See also:

`numpy.diagonal`
equivalent function

method

`recarray.dot (other, /, out=None)`

Refer to [*numpy.dot*](#) for full documentation.

See also:

[*numpy.dot*](#)

equivalent function

method

`recarray.dump (file)`

Dump a pickle of the array to the specified file. The array can be read back with `pickle.load` or `numpy.load`.

Parameters

file

[str or Path] A string naming the dump file.

method

`recarray.dumps ()`

Returns the pickle of the array as a string. `pickle.loads` will convert the string back to an array.

Parameters

None

method

`recarray.fill (value)`

Fill the array with a scalar value.

Parameters

value

[scalar] All elements of *a* will be assigned this value.

Examples

```
>>> import numpy as np
>>> a = np.array([1, 2])
>>> a.fill(0)
>>> a
array([0, 0])
>>> a = np.empty(2)
>>> a.fill(1)
>>> a
array([1., 1.]
```

`Fill` expects a scalar value and always behaves the same as assigning to a single array element. The following is a rare example where this distinction is important:

```
>>> a = np.array([None, None], dtype=np.object_)
>>> a[0] = np.array(3)
>>> a
array([array(3), None], dtype=object)
>>> a.fill(np.array(3))
```

(continues on next page)

(continued from previous page)

```
>>> a
array([array(3), array(3)], dtype=object)
```

Where other forms of assignments will unpack the array being assigned:

```
>>> a[...] = np.array(3)
>>> a
array([3, 3], dtype=object)
```

method

`recarray.flatten` (*order='C'*)

Return a copy of the array collapsed into one dimension.

Parameters

order

[{'C', 'F', 'A', 'K'}, optional] 'C' means to flatten in row-major (C-style) order. 'F' means to flatten in column-major (Fortran- style) order. 'A' means to flatten in column-major order if *a* is Fortran *contiguous* in memory, row-major order otherwise. 'K' means to flatten *a* in the order the elements occur in memory. The default is 'C'.

Returns

y

[ndarray] A copy of the input array, flattened to one dimension.

See also:

[*ravel*](#)

Return a flattened array.

flat

A 1-D flat iterator over the array.

Examples

```
>>> import numpy as np
>>> a = np.array([[1,2], [3,4]])
>>> a.flatten()
array([1, 2, 3, 4])
>>> a.flatten('F')
array([1, 3, 2, 4])
```

method

`recarray.getfield` (*dtype, offset=0*)

Returns a field of the given array as a certain type.

A field is a view of the array data with a given data-type. The values in the view are determined by the given type and the offset into the current array in bytes. The offset needs to be such that the view dtype fits in the array dtype; for example an array of dtype `complex128` has 16-byte elements. If taking a view with a 32-bit integer (4 bytes), the offset needs to be between 0 and 12 bytes.

Parameters

dtype

[str or dtype] The data type of the view. The dtype size of the view can not be larger than that of the array itself.

offset

[int] Number of bytes to skip before beginning the element view.

Examples

```
>>> import numpy as np
>>> x = np.diag([1.+1.j]*2)
>>> x[1, 1] = 2 + 4.j
>>> x
array([[1.+1.j,  0.+0.j],
       [0.+0.j,  2.+4.j]])
>>> x.getfield(np.float64)
array([[1.,  0.],
       [0.,  2.]])
```

By choosing an offset of 8 bytes we can select the complex part of the array for our view:

```
>>> x.getfield(np.float64, offset=8)
array([[1.,  0.],
       [0.,  4.]])
```

method

`recarray.item(*args)`

Copy an element of an array to a standard Python scalar and return it.

Parameters***args**

[Arguments (variable number and type)]

- none: in this case, the method only works for arrays with one element (*a.size == 1*), which element is copied into a standard Python scalar object and returned.
- int_type: this argument is interpreted as a flat index into the array, specifying which element to copy and return.
- tuple of int_types: functions as does a single int_type argument, except that the argument is interpreted as an nd-index into the array.

Returns**z**

[Standard Python scalar object] A copy of the specified element of the array as a suitable Python scalar

Notes

When the data type of *a* is longdouble or clongdouble, `item()` returns a scalar array object because there is no available Python scalar that would not lose information. Void arrays return a buffer object for `item()`, unless fields are defined, in which case a tuple is returned.

item is very similar to `a[args]`, except, instead of an array scalar, a standard Python scalar is returned. This can be useful for speeding up access to elements of the array and doing arithmetic on elements of the array using Python's optimized math.

Examples

```
>>> import numpy as np
>>> np.random.seed(123)
>>> x = np.random.randint(9, size=(3, 3))
>>> x
array([[2, 2, 6],
       [1, 3, 6],
       [1, 0, 1]])
>>> x.item(3)
1
>>> x.item(7)
0
>>> x.item((0, 1))
2
>>> x.item((2, 2))
1
```

For an array with object dtype, elements are returned as-is.

```
>>> a = np.array([np.int64(1)], dtype=np.object_)
>>> a.item() #return np.int64
np.int64(1)
```

method

`recarray.max` (*axis=None, out=None, *, keepdims=<no value>, initial=<no value>, where=<no value>*)

Return the maximum along a given axis.

Refer to `numpy.amax` for full documentation.

See also:

`numpy.amax`

equivalent function

method

`recarray.mean` (*axis=None, dtype=None, out=None, *, keepdims=<no value>, where=<no value>*)

Returns the average of the array elements along given axis.

Refer to `numpy.mean` for full documentation.

See also:

`numpy.mean`

equivalent function

method

`recarray.min` (*axis=None*, *out=None*, *, *keepdims=<no value>*, *initial=<no value>*, *where=<no value>*)

Return the minimum along a given axis.

Refer to `numpy.amin` for full documentation.

See also:

`numpy.amin`

equivalent function

method

`recarray.nonzero` ()

Return the indices of the elements that are non-zero.

Refer to `numpy.nonzero` for full documentation.

See also:

`numpy.nonzero`

equivalent function

method

`recarray.partition` (*kth*, *axis=-1*, *kind='introselect'*, *order=None*)

Partially sorts the elements in the array in such a way that the value of the element in *k*-th position is in the position it would be in a sorted array. In the output array, all elements smaller than the *k*-th element are located to the left of this element and all equal or greater are located to its right. The ordering of the elements in the two partitions on the either side of the *k*-th element in the output array is undefined.

Parameters

kth

[int or sequence of ints] Element index to partition by. The *k*th element value will be in its final sorted position and all smaller elements will be moved before it and all equal or greater elements behind it. The order of all elements in the partitions is undefined. If provided with a sequence of *kth* it will partition all elements indexed by *kth* of them into their sorted position at once.

Deprecated since version 1.22.0: Passing booleans as index is deprecated.

axis

[int, optional] Axis along which to sort. Default is -1, which means sort along the last axis.

kind

[{'introselect'}, optional] Selection algorithm. Default is 'introselect'.

order

[str or list of str, optional] When *a* is an array with fields defined, this argument specifies which fields to compare first, second, etc. A single field can be specified as a string, and not all fields need to be specified, but unspecified fields will still be used, in the order in which they come up in the dtype, to break ties.

See also:

`numpy.partition`

Return a partitioned copy of an array.

argpartition

Indirect partition.

sort

Full sort.

Notes

See `np.partition` for notes on the different algorithms.

Examples

```
>>> import numpy as np
>>> a = np.array([3, 4, 2, 1])
>>> a.partition(3)
>>> a
array([2, 1, 3, 4]) # may vary
```

```
>>> a.partition((1, 3))
>>> a
array([1, 2, 3, 4])
```

method

`recarray.prod` (*axis=None, dtype=None, out=None, *, keepdims=<no value>, initial=<no value>, where=<no value>*)

Return the product of the array elements over the given axis

Refer to `numpy.prod` for full documentation.

See also:

`numpy.prod`

equivalent function

method

`recarray.put` (*indices, values, mode='raise'*)

Set `a.flat[n] = values[n]` for all `n` in indices.

Refer to `numpy.put` for full documentation.

See also:

`numpy.put`

equivalent function

method

`recarray.ravel` (*order='C'*)

Return a flattened array.

Refer to `numpy.ravel` for full documentation.

See also:

`numpy.ravel`

equivalent function

`ndarray.flat`

a flat iterator on the array.

method

`recarray.repeat(repeats, axis=None)`

Repeat elements of an array.

Refer to `numpy.repeat` for full documentation.

See also:

`numpy.repeat`

equivalent function

method

`recarray.reshape(shape, /, *, order='C', copy=None)` `a.reshape(*shape, order='C', copy=None)`

`recarray.reshape(*shape, order='C', copy=None) → None`

Returns an array containing the same data with a new shape.

Refer to `numpy.reshape` for full documentation.

See also:

`numpy.reshape`

equivalent function

Notes

Unlike the free function `numpy.reshape`, this method on `ndarray` allows the elements of the shape parameter to be passed in as separate arguments. For example, `a.reshape(4, 2)` is equivalent to `a.reshape((4, 2))`.

method

`recarray.resize(new_shape, /, *, refcheck=True)` `a.resize(*new_shape, refcheck=True)`

`recarray.resize(*new_shape, refcheck=True) → None`

Change shape and size of array in-place.

Parameters

new_shape

[tuple of ints, or *n* ints] Shape of resized array.

refcheck

[bool, optional] If False, reference count will not be checked. Default is True. See Notes below for more explanation.

Returns

None

Raises

ValueError

If *a* does not own its own data or references or views to may exist.

See also:**`resize`**

Return a new array with the specified shape.

Notes

This reallocates space for the data area if necessary.

Only contiguous arrays (data elements consecutive in memory) can be resized.

Reallocating arrays in-place can often lead to memory fragmentation and should be avoided. If the goal is to reclaim over-allocated memory, alternatives are to create a view or a copy of just the desired data, or using two passes to build the array: one to cheaply determine the shape and another to allocate and fill. Benchmark your use case to determine what is optimum. You may be surprised to find `resize` actually slows down or bloats your application.

The purpose of the reference count check is to make sure you do not use this array as a buffer for another Python object and then reallocate the memory.

On Python 3.13 and older, the check allows objects with exactly one reference to be reallocated in-place. On Python 3.14 and newer, the array must be uniquely referenced. See [1] for more details.

If you are sure that you have not shared the memory for this array with another Python object, then you may safely set `refcheck` to `False`.

References

[1]

Examples

Shrinking an array: array is flattened (in the order that the data are stored in memory), resized, and reshaped:

```
>>> import numpy as np
```

```
>>> a = np.array([[0, 1], [2, 3]], order='C')
>>> a.resize((2, 1))
>>> a
array([[0],
       [1]])
```

```
>>> a = np.array([[0, 1], [2, 3]], order='F')
>>> a.resize((2, 1))
>>> a
array([[0],
       [2]])
```

Enlarging an array: as above, but missing entries are filled with zeros:

```
>>> b = np.array([[0, 1], [2, 3]])
>>> b.resize(2, 3) # new_shape parameter doesn't have to be a tuple
>>> b
array([[0, 1, 2],
       [3, 0, 0]])
```

Referencing an array prevents resizing...

```
>>> c = a
>>> a.resize((1, 1))
Traceback (most recent call last):
...
ValueError: cannot resize an array that references or is referenced ...
```

Unless *refcheck* is False:

```
>>> a.resize((1, 1), refcheck=False)
>>> a
array([[0]])
>>> c
array([[0]])
```

method

`recarray.round(decimals=0, out=None)`

Return *a* with each element rounded to the given number of decimals.

Refer to [*numpy.around*](#) for full documentation.

See also:

[*numpy.around*](#)
equivalent function

method

`recarray.searchsorted(v, side='left', sorter=None)`

Find indices where elements of *v* should be inserted in *a* to maintain order.

For full documentation, see [*numpy.searchsorted*](#).

See also:

[*numpy.searchsorted*](#)
equivalent function

method

`recarray.setfield(val, dtype, offset=0)`

Put a value into a specified place in a field defined by a data-type.

Place *val* into *a*'s field defined by *dtype* and beginning *offset* bytes into the field.

Parameters

val
[object] Value to be placed in field.

dtype
[dtype object] Data-type of the field in which to place *val*.

offset
[int, optional] The number of bytes into the field at which to place *val*.

Returns

None

See also:

getfield

Examples

```
>>> import numpy as np
>>> x = np.eye(3)
>>> x.getfield(np.float64)
array([[1.,  0.,  0.],
       [0.,  1.,  0.],
       [0.,  0.,  1.]])
>>> x.setfield(3, np.int32)
>>> x.getfield(np.int32)
array([[3, 3, 3],
       [3, 3, 3],
       [3, 3, 3]], dtype=int32)
>>> x
array([[1.0e+000, 1.5e-323, 1.5e-323],
       [1.5e-323, 1.0e+000, 1.5e-323],
       [1.5e-323, 1.5e-323, 1.0e+000]])
>>> x.setfield(np.eye(3), np.int32)
>>> x
array([[1.,  0.,  0.],
       [0.,  1.,  0.],
       [0.,  0.,  1.]])
```

method

`recarray.setflags (write=None, align=None, uic=None)`

Set array flags WRITEABLE, ALIGNED, WRITEBACKIFCOPY, respectively.

These Boolean-valued flags affect how numpy interprets the memory area used by *a* (see Notes below). The ALIGNED flag can only be set to True if the data is actually aligned according to the type. The WRITEBACKIFCOPY flag can never be set to True. The flag WRITEABLE can only be set to True if the array owns its own memory, or the ultimate owner of the memory exposes a writeable buffer interface, or is a string. (The exception for string is made so that unpickling can be done without copying memory.)

Parameters

write

[bool, optional] Describes whether or not *a* can be written to.

align

[bool, optional] Describes whether or not *a* is aligned properly for its type.

uic

[bool, optional] Describes whether or not *a* is a copy of another “base” array.

Notes

Array flags provide information about how the memory area used for the array is to be interpreted. There are 7 Boolean flags in use, only three of which can be changed by the user: `WRITEBACKIFCOPY`, `WRITEABLE`, and `ALIGNED`.

`WRITEABLE` (W) the data area can be written to;

`ALIGNED` (A) the data and strides are aligned appropriately for the hardware (as determined by the compiler);

`WRITEBACKIFCOPY` (X) this array is a copy of some other array (referenced by `.base`). When the C-API function `PyArray_ResolveWritebackIfCopy` is called, the base array will be updated with the contents of this array.

All flags can be accessed using the single (upper case) letter as well as the full name.

Examples

```
>>> import numpy as np
>>> y = np.array([[3, 1, 7],
...               [2, 0, 0],
...               [8, 5, 9]])
>>> y
array([[3, 1, 7],
       [2, 0, 0],
       [8, 5, 9]])
>>> y.flags
C_CONTIGUOUS : True
F_CONTIGUOUS : False
OWNDATA : True
WRITEABLE : True
ALIGNED : True
WRITEBACKIFCOPY : False
>>> y.setflags(write=0, align=0)
>>> y.flags
C_CONTIGUOUS : True
F_CONTIGUOUS : False
OWNDATA : True
WRITEABLE : False
ALIGNED : False
WRITEBACKIFCOPY : False
>>> y.setflags(uic=1)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: cannot set WRITEBACKIFCOPY flag to True
```

method

`recarray.sort` (*axis=-1, kind=None, order=None, *, stable=None, descending=None*)

Sort an array in-place. Refer to [numpy.sort](#) for full documentation.

Parameters

axis

[int, optional] Axis along which to sort. Default is -1, which means sort along the last axis.

kind

[{'quicksort', 'mergesort', 'heapsort', 'stable'}, optional] Sorting algorithm. The default is

'quicksort'. Note that both 'stable' and 'mergesort' use timsort under the covers and, in general, the actual implementation will vary with datatype. The 'mergesort' option is retained for backwards compatibility.

order

[str or list of str, optional] When *a* is an array with fields defined, this argument specifies which fields to compare first, second, etc. A single field can be specified as a string, and not all fields need be specified, but unspecified fields will still be used, in the order in which they come up in the dtype, to break ties.

stable

[bool, optional] Sort stability. If `True`, the returned array will maintain the relative order of a values which compare as equal. If `False` or `None`, this is not guaranteed. Internally, this option selects `kind='stable'`. Default: `None`.

New in version 2.0.0.

See also:

`numpy.sort`

Return a sorted copy of an array.

`numpy.argsort`

Indirect sort.

`numpy.lexsort`

Indirect stable sort on multiple keys.

`numpy.searchsorted`

Find elements in sorted array.

`numpy.partition`

Partial sort.

Notes

See `numpy.sort` for notes on the different sorting algorithms.

Examples

```
>>> import numpy as np
>>> a = np.array([[1,4], [3,1]])
>>> a.sort(axis=1)
>>> a
array([[1, 4],
       [1, 3]])
>>> a.sort(axis=0)
>>> a
array([[1, 3],
       [1, 4]])
```

Use the *order* keyword to specify a field to use when sorting a structured array:

```
>>> a = np.array([('a', 2), ('c', 1)], dtype=[('x', 'S1'), ('y', int)])
>>> a.sort(order='y')
>>> a
```

(continues on next page)

(continued from previous page)

```
array([(b'c', 1), (b'a', 2)],  
      dtype=[('x', 'S1'), ('y', '<i8')])
```

method

`recarray.squeeze(axis=None)`

Remove axes of length one from *a*.

Refer to [`numpy.squeeze`](#) for full documentation.

See also:

[`numpy.squeeze`](#)

equivalent function

method

`recarray.std(axis=None, dtype=None, out=None, ddof=0, *, keepdims=<no value>, where=<no value>, mean=<no value>)`

Returns the standard deviation of the array elements along given axis.

Refer to [`numpy.std`](#) for full documentation.

See also:

[`numpy.std`](#)

equivalent function

method

`recarray.sum(axis=None, dtype=None, out=None, *, keepdims=<no value>, initial=<no value>, where=<no value>)`

Return the sum of the array elements over the given axis.

Refer to [`numpy.sum`](#) for full documentation.

See also:

[`numpy.sum`](#)

equivalent function

method

`recarray.swapaxes(axis1, axis2, /)`

Return a view of the array with *axis1* and *axis2* interchanged.

Refer to [`numpy.swapaxes`](#) for full documentation.

See also:

[`numpy.swapaxes`](#)

equivalent function

method

`recarray.take` (*indices*, *axis=None*, *out=None*, *mode='raise'*)

Return an array formed from the elements of *a* at the given indices.

Refer to [`numpy.take`](#) for full documentation.

See also:

[`numpy.take`](#)

equivalent function

method

`recarray.to_device` (*device*, */*, ***, *stream=None*)

For Array API compatibility. Since NumPy only supports CPU arrays, this method is a no-op that returns the same array.

Parameters

device

["cpu"] Must be "cpu".

stream

[None, optional] Currently unsupported.

Returns

out

[Self] Returns the same array.

method

`recarray.tobytes` (*order='C'*)

Construct Python bytes containing the raw data bytes in the array.

Constructs Python bytes showing a copy of the raw contents of data memory. The bytes object is produced in C-order by default. This behavior is controlled by the `order` parameter.

Parameters

order

[['C', 'F', 'A'], optional] Controls the memory layout of the bytes object. 'C' means C-order, 'F' means F-order, 'A' (short for *Any*) means 'F' if *a* is Fortran contiguous, 'C' otherwise. Default is 'C'.

Returns

s

[bytes] Python bytes exhibiting a copy of *a*'s raw data.

See also:

[`frombuffer`](#)

Inverse of this operation, construct a 1-dimensional array from Python bytes.

Examples

```
>>> import numpy as np
>>> x = np.array([[0, 1], [2, 3]], dtype='<u2')
>>> x.tobytes()
b'\x00\x00\x01\x00\x02\x00\x03\x00'
>>> x.tobytes('C') == x.tobytes()
True
>>> x.tobytes('F')
b'\x00\x00\x02\x00\x01\x00\x03\x00'
```

method

`recarray.tofile(fid, /, sep="", format='%s')`

Write array to a file as text or binary (default).

Data is always written in ‘C’ order, independent of the order of *a*. The data produced by this method can be recovered using the function `fromfile()`.

Parameters

fid

[file or str or Path] An open file object, or a string containing a filename.

sep

[str] Separator between array items for text output. If “” (empty), a binary file is written, equivalent to `file.write(a.tobytes())`.

format

[str] Format string for text file output. Each entry in the array is formatted to text by first converting it to the closest Python type, and then using “format” % item.

Notes

This is a convenience function for quick storage of array data. Information on endianness and precision is lost, so this method is not a good choice for files intended to archive data or transport data between machines with different endianness. Some of these problems can be overcome by outputting the data as text files, at the expense of speed and file size.

When `fid` is a file object, array contents are directly written to the file, bypassing the file object’s `write` method. As a result, `tofile` cannot be used with files objects supporting compression (e.g., `GzipFile`) or file-like objects that do not support `fileno()` (e.g., `BytesIO`).

method

`recarray.tolist()`

Return the array as an `a.ndim`-levels deep nested list of Python scalars.

Return a copy of the array data as a (nested) Python list. Data items are converted to the nearest compatible builtin Python type, via the *item* method.

If `a.ndim` is 0, then since the depth of the nested list is 0, it will not be a list at all, but a simple Python scalar.

Parameters

none

Returns

y
 [object, or list of object, or list of list of object, or ...] The possibly nested list of array elements.

Notes

The array may be recreated via `a = np.array(a.tolist())`, although this may sometimes lose precision.

Examples

For a 1D array, `a.tolist()` is almost the same as `list(a)`, except that `tolist` changes numpy scalars to Python scalars:

```
>>> import numpy as np
>>> a = np.uint32([1, 2])
>>> a_list = list(a)
>>> a_list
[np.uint32(1), np.uint32(2)]
>>> type(a_list[0])
<class 'numpy.uint32'>
>>> a_tolist = a.tolist()
>>> a_tolist
[1, 2]
>>> type(a_tolist[0])
<class 'int'>
```

Additionally, for a 2D array, `tolist` applies recursively:

```
>>> a = np.array([[1, 2], [3, 4]])
>>> list(a)
[array([1, 2]), array([3, 4])]
>>> a.tolist()
[[1, 2], [3, 4]]
```

The base case for this recursion is a 0D array:

```
>>> a = np.array(1)
>>> list(a)
Traceback (most recent call last):
...
TypeError: iteration over a 0-d array
>>> a.tolist()
1
```

method

`recarray.t.trace` (*offset=0, axis1=0, axis2=1, dtype=None, out=None*)

Return the sum along diagonals of the array.

Refer to `numpy.trace` for full documentation.

See also:

`numpy.trace`

equivalent function

method

`recarray.transpose(*axes)`

Returns a view of the array with axes transposed.

Refer to `numpy.transpose` for full documentation.

Parameters

axes

[None, tuple of ints, or *n* ints]

- None or no argument: reverses the order of the axes.
- tuple of ints: *i* in the *j*-th place in the tuple means that the array's *i*-th axis becomes the transposed array's *j*-th axis.
- *n* ints: same as an *n*-tuple of the same ints (this form is intended simply as a “convenience” alternative to the tuple form).

Returns

p

[ndarray] View of the array with its axes suitably permuted.

See also:

`transpose`

Equivalent function.

`ndarray.T`

Array property returning the array transposed.

`ndarray.reshape`

Return a reshaped ndarray without changing data.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> a
array([[1, 2],
       [3, 4]])
>>> a.transpose()
array([[1, 3],
       [2, 4]])
>>> a.transpose((1, 0))
array([[1, 3],
       [2, 4]])
>>> a.transpose(1, 0)
array([[1, 3],
       [2, 4]])
```

```
>>> a = np.array([1, 2, 3, 4])
>>> a
array([1, 2, 3, 4])
>>> a.transpose()
array([1, 2, 3, 4])
```

method

`recarray.var` (*axis=None, dtype=None, out=None, ddof=0, *, keepdims=<no value>, where=<no value>, mean=<no value>*)

Returns the variance of the array elements, along given axis.

Refer to `numpy.var` for full documentation.

See also:

`numpy.var`
equivalent function

method

`recarray.view` (*[dtype][, type]*)

New view of array with the same data.

Note: Passing `None` for `dtype` is different from omitting the parameter, since the former invokes `dtype(None)` which is an alias for `dtype(np.float64)`.

Parameters

dtype

[data-type or ndarray sub-class, optional] Data-type descriptor of the returned view, e.g., `float32` or `int16`. Omitting it results in the view having the same data-type as *a*. This argument can also be specified as an ndarray sub-class, which then specifies the type of the returned object (this is equivalent to setting the `type` parameter).

type

[Python type, optional] Type of the returned view, e.g., `ndarray` or `matrix`. Again, omission of the parameter results in type preservation.

Notes

`a.view()` is used two different ways:

`a.view(some_dtype)` or `a.view(dtype=some_dtype)` constructs a view of the array's memory with a different data-type. This can cause a reinterpretation of the bytes of memory.

`a.view(ndarray_subclass)` or `a.view(type=ndarray_subclass)` just returns an instance of `ndarray_subclass` that looks at the same array (same shape, dtype, etc.) This does not cause a reinterpretation of the memory.

For `a.view(some_dtype)`, if `some_dtype` has a different number of bytes per entry than the previous dtype (for example, converting a regular array to a structured array), then the last axis of *a* must be contiguous. This axis will be resized in the result.

Changed in version 1.23.0: Only the last axis needs to be contiguous. Previously, the entire array had to be C-contiguous.

Examples

```
>>> import numpy as np
>>> x = np.array([(-1, 2)], dtype=[('a', np.int8), ('b', np.int8)])
```

Viewing array data using a different type and dtype:

```
>>> nonneg = np.dtype [("a", np.uint8), ("b", np.uint8)]
>>> y = x.view(dtype=nonneg, type=np.recarray)
>>> x["a"]
array([-1], dtype=int8)
>>> y.a
array([255], dtype=uint8)
```

Creating a view on a structured array so it can be used in calculations

```
>>> x = np.array([(1, 2), (3, 4)], dtype=[('a', np.int8), ('b', np.int8)])
>>> xv = x.view(dtype=np.int8).reshape(-1, 2)
>>> xv
array([[1, 2],
       [3, 4]], dtype=int8)
>>> xv.mean(0)
array([2., 3.])
```

Making changes to the view changes the underlying array

```
>>> xv[0, 1] = 20
>>> x
array([(1, 20), (3, 4)], dtype=[('a', 'i1'), ('b', 'i1')])
```

Using a view to convert an array to a recarray:

```
>>> z = x.view(np.recarray)
>>> z.a
array([1, 3], dtype=int8)
```

Views share data:

```
>>> x[0] = (9, 10)
>>> z[0]
np.record((9, 10), dtype=[('a', 'i1'), ('b', 'i1')])
```

Views that change the dtype size (bytes per entry) should normally be avoided on arrays defined by slices, transposes, fortran-ordering, etc.:

```
>>> x = np.array([[1, 2, 3], [4, 5, 6]], dtype=np.int16)
>>> y = x[:, ::2]
>>> y
array([[1, 3],
       [4, 6]], dtype=int16)
>>> y.view(dtype=[('width', np.int16), ('length', np.int16)])
Traceback (most recent call last):
...
ValueError: To change to a dtype of a different size, the last axis must be
↳ contiguous
>>> z = y.copy()
>>> z.view(dtype=[('width', np.int16), ('length', np.int16)])
```

(continues on next page)

(continued from previous page)

```
array([[ (1, 3)],
       [(4, 6)]], dtype=[('width', '<i2'), ('length', '<i2')])
```

However, views that change dtype are totally fine for arrays with a contiguous last axis, even if the rest of the axes are not C-contiguous:

```
>>> x = np.arange(2 * 3 * 4, dtype=np.int8).reshape(2, 3, 4)
>>> x.transpose(1, 0, 2).view(np.int16)
array([[[ 256,  770],
        [3340, 3854]],

       [[1284, 1798],
        [4368, 4882]],

       [[2312, 2826],
        [5396, 5910]]], dtype=int16)
```

field

Returns

rec

[recarray] Empty array of the given shape and type.

Other Parameters

titles

[tuple of str, optional] Aliases for column names. For example, if *names* were ('x', 'y', 'z') and *titles* is ('x_coordinate', 'y_coordinate', 'z_coordinate'), then `arr['x']` is equivalent to both `arr.x` and `arr.x_coordinate`.

byteorder

[{'<', '>', '='}, optional] Byte-order for all fields.

aligned

[bool, optional] Align the fields in memory as the C-compiler would.

strides

[tuple of ints, optional] Buffer (*buf*) is interpreted according to these strides (strides define how many bytes each array element, row, column, etc. occupy in memory).

offset

[int, optional] Start reading buffer (*buf*) from this offset onwards.

order

[{'C', 'F'}, optional] Row-major (C-style) or column-major (Fortran-style) order.

See also:

[`numpy.rec.fromrecords`](#)

Construct a record array from data.

[`numpy.record`](#)

fundamental data-type for `recarray`.

[`numpy.rec.format\_parser`](#)

determine data-type from formats, names, titles.

Notes

This constructor can be compared to `empty`: it creates a new record array but does not fill it with data. To create a record array from data, use one of the following methods:

1. Create a standard `ndarray` and convert it to a record array, using `arr.view(np.recarray)`
2. Use the `buf` keyword.
3. Use `np.rec.fromrecords`.

Examples

Create an array with two fields, `x` and `y`:

```
>>> import numpy as np
>>> x = np.array([(1.0, 2), (3.0, 4)], dtype=[('x', '<f8'), ('y', '<i8')])
>>> x
array([(1., 2), (3., 4)], dtype=[('x', '<f8'), ('y', '<i8')])
```

```
>>> x['x']
array([1., 3.])
```

View the array as a record array:

```
>>> x = x.view(np.recarray)
```

```
>>> x.x
array([1., 3.])
```

```
>>> x.y
array([2, 4])
```

Create a new, empty record array:

```
>>> np.recarray((2,),
... dtype=[('x', int), ('y', float), ('z', int)])
rec.array([(-1073741821, 1.2249118382103472e-301, 24547520),
          (3471280, 1.2134086255804012e-316, 0)],
          dtype=[('x', '<i4'), ('y', '<f8'), ('z', '<i4')])
```

class `numpy.record` (*length_or_data*, /, *dtype=None*)

A data-type scalar that allows field access as attribute lookup.

Attributes

T

Scalar attribute identical to `ndarray.T`.

base

base object

data

Pointer to start of data.

device

dtype

dtype object

flags
integer value of flags

flat
A 1-D view of the scalar.

imag
The imaginary part of the scalar.

itemsize
The length of one element in bytes.

nbytes

ndim
The number of array dimensions.

real
The real part of the scalar.

shape
Tuple of array dimensions.

size
The number of elements in the gentype.

strides
Tuple of bytes steps in each dimension.

Methods

<i>all</i> (/[, axis, out, keepdims, where])	Scalar method identical to <i>ndarray.all</i> .
<i>any</i> (/[, axis, out, keepdims, where])	Scalar method identical to <i>ndarray.any</i> .
<i>argmax</i> (/[, axis, out, keepdims])	Scalar method identical to <i>ndarray.argmax</i> .
<i>argmin</i> (/[, axis, out, keepdims])	Scalar method identical to <i>ndarray.argmin</i> .

method

`record.all (/[, axis=None, out=None, keepdims=False, *, where=True])`

Scalar method identical to `ndarray.all`.

method

`record.any (/[, axis=None, out=None, keepdims=False, *, where=True])`

Scalar method identical to `ndarray.any`.

method

`record.argmax (/[, axis=None, out=None, *, keepdims=False])`

Scalar method identical to `ndarray.argmax`.

method

`record.argmin (/[, axis=None, out=None, *, keepdims=False])`

Scalar method identical to `ndarray.argmin`.

method

`record.argsort (/[, axis=-1, kind=None, order=None, *, stable=None, descending=None])`

Scalar method identical to `ndarray.argsort`.

method

`record.astype (/, dtype, order='K', casting='unsafe', subok=True, copy=True)`

Scalar method identical to `ndarray.astype`.

method

`record.byteswap (/, inplace=False)`

Scalar method identical to `ndarray.byteswap`.

method

`record.choose (/, choices, out=None, mode='raise')`

Scalar method identical to `ndarray.choose`.

method

`record.clip (/, min=None, max=None, out=None, **kwargs)`

Scalar method identical to `ndarray.clip`.

method

`record.compress (/, condition, axis=None, out=None)`

Scalar method identical to `ndarray.compress`.

method

`record.conj (/)`

Scalar method identical to `ndarray.conj`.

method

`record.conjugate (/)`

Scalar method identical to `ndarray.conjugate`.

method

`record.copy (/, order='C')`

Scalar method identical to `ndarray.copy`.

method

`record.cumprod (/, axis=None, dtype=None, out=None)`

Scalar method identical to `ndarray.cumprod`.

method

`record.cumsum (/, axis=None, dtype=None, out=None)`

Scalar method identical to `ndarray.cumsum`.

method

`record.diagonal (/, offset=0, axis1=0, axis2=1)`

Scalar method identical to `ndarray.diagonal`.

method

`record.dump (/, file)`

Scalar method identical to `ndarray.dump`.

method

`record.dumps (/)`
Scalar method identical to `ndarray.dumps`.

method

`record.fill (/, value)`
Scalar method identical to `ndarray.fill`.

method

`record.flatten (/, order='C')`
Scalar method identical to `ndarray.flatten`.

method

`record.getfield ()`
Scalar method identical to `ndarray.getfield`.

method

`record.item (*args)`
Scalar method identical to `ndarray.item`.

method

`record.max (/, axis=None, out=None, **kwargs)`
Scalar method identical to `ndarray.max`.

method

`record.mean (/, axis=None, dtype=None, out=None, **kwargs)`
Scalar method identical to `ndarray.mean`.

method

`record.min (/, axis=None, out=None, **kwargs)`
Scalar method identical to `ndarray.min`.

method

`record.nonzero (/)`
Scalar method identical to `ndarray.nonzero`.

method

`record.pprint ()`
Pretty-print all fields.

method

`record.prod (/, axis=None, dtype=None, out=None, **kwargs)`
Scalar method identical to `ndarray.prod`.

method

`record.put (indices, values, /, mode='raise')`
Scalar method identical to `ndarray.put`.

method

`record.ravel (/, order='C')`
 Scalar method identical to `ndarray.ravel`.
 method

`record.repeat (repeats, /, axis=None)`
 Scalar method identical to `ndarray.repeat`.
 method

`record.reshape (*shape, order='C', copy=None)`
 Scalar method identical to `ndarray.reshape`.
 method

`record.resize (*new_shape, refcheck=True)`
 Scalar method identical to `ndarray.resize`.
 method

`record.round (/, decimals=0, out=None)`
 Scalar method identical to `ndarray.round`.
 method

`record.searchsorted (v, /, side='left', sorter=None)`
 Scalar method identical to `ndarray.searchsorted`.
 method

`record.setfield ()`
 Scalar method identical to `ndarray.setfield`.
 method

`record.setflags (*, write=None, align=None, uic=None)`
 Scalar method identical to `ndarray.setflags`.
 method

`record.sort (/, axis=-1, kind=None, order=None, *, stable=None, descending=None)`
 Scalar method identical to `ndarray.sort`.
 method

`record.squeeze (/, axis=None)`
 Scalar method identical to `ndarray.squeeze`.
 method

`record.std (/, axis=None, dtype=None, out=None, ddof=0, **kwargs)`
 Scalar method identical to `ndarray.std`.
 method

`record.sum (/, axis=None, dtype=None, out=None, **kwargs)`
 Scalar method identical to `ndarray.sum`.
 method

`record.swapaxes (axis1, axis2, /)`
Scalar method identical to `ndarray.swapaxes`.

method

`record.take (indices, /, axis=None, out=None, mode='raise')`
Scalar method identical to `ndarray.take`.

method

`record.to_device (device, *, stream=None)`
Scalar method identical to `ndarray.to_device`.

method

`record.tobytes (/, order='C')`
Scalar method identical to `ndarray.tobytes`.

method

`record.tofile (fid, /, sep=",", format='%s')`
Scalar method identical to `ndarray.tofile`.

method

`record.tolist (/)`
Scalar method identical to `ndarray.tolist`.

method

`record.trace (/, offset=0, axis1=0, axis2=1, dtype=None, out=None)`
Scalar method identical to `ndarray.trace`.

method

`record.transpose (*axes)`
Scalar method identical to `ndarray.transpose`.

method

`record.var (/, axis=None, dtype=None, out=None, ddof=0, **kwargs)`
Scalar method identical to `ndarray.var`.

method

`record.view (*args, **kwargs)`
Scalar method identical to `ndarray.view`.

Note: The pandas DataFrame is more powerful than record array. If possible, please use pandas DataFrame instead.

Masked arrays (`numpy.ma`)

See also:

Masked arrays

Standard container class

For backward compatibility and as a standard “container” class, the `UserArray` from Numeric has been brought over to NumPy and named `numpy.lib.user_array.container`. The container class is a Python class whose `self.array` attribute is an `ndarray`. Multiple inheritance is probably easier with `numpy.lib.user_array.container` than with the `ndarray` itself and so it is included by default. It is not documented here beyond mentioning its existence because you are encouraged to use the `ndarray` class directly if you can.

```
numpy.lib.user_array.container(data[, ...])    Standard container-class for easy multiple-inheritance.
```

```
class numpy.lib.user_array.container (data, dtype=None, copy=True)
```

Standard container-class for easy multiple-inheritance.

Methods

copy
byteswap
astype

Array iterators

Iterators are a powerful concept for array processing. Essentially, iterators implement a generalized for-loop. If *myiter* is an iterator object, then the Python code:

```
for val in myiter:
    ...
    some code involving val
    ...
```

calls `val = next(myiter)` repeatedly until `StopIteration` is raised by the iterator. There are several ways to iterate over an array that may be useful: default iteration, flat iteration, and *N*-dimensional enumeration.

Default iteration

The default iterator of an `ndarray` object is the default Python iterator of a sequence type. Thus, when the array object itself is used as an iterator. The default behavior is equivalent to:

```
for i in range(arr.shape[0]):
    val = arr[i]
```

This default iterator selects a sub-array of dimension $N - 1$ from the array. This can be a useful construct for defining recursive algorithms. To loop over the entire array requires *N* for-loops.

```
>>> import numpy as np
>>> a = np.arange(24).reshape(3,2,4) + 10
>>> for val in a:
...     print('item:', val)
item: [[10 11 12 13]
[14 15 16 17]]
item: [[18 19 20 21]
[22 23 24 25]]
item: [[26 27 28 29]
[30 31 32 33]]
```

Flat iteration

*ndarray.flat*A 1-D iterator over the array.

As mentioned previously, the flat attribute of ndarray objects returns an iterator that will cycle over the entire array in C-style contiguous order.

```
>>> import numpy as np
>>> for i, val in enumerate(a.flat):
...     if i%5 == 0: print(i, val)
0 10
5 15
10 20
15 25
20 30
```

Here, I've used the built-in enumerate iterator to return the iterator index as well as the value.

N-dimensional enumeration

*ndenumerate(arr)*Multidimensional index iterator.

class `numpy.ndenumerate` (*arr*)

Multidimensional index iterator.

Return an iterator yielding pairs of array coordinates and values.

Parameters

arr

[ndarray] Input array.

See also:

ndindex, *flatiter*

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> for index, x in np.ndenumerate(a):
...     print(index, x)
(0, 0) 1
(0, 1) 2
(1, 0) 3
(1, 1) 4
```

Sometimes it may be useful to get the N-dimensional index while iterating. The `ndenumerate` iterator can achieve this.

```
>>> import numpy as np
>>> for i, val in np.ndenumerate(a):
...     if sum(i)%5 == 0:
...         print(i, val)
(0, 0, 0) 10
(1, 1, 3) 25
(2, 0, 3) 29
(2, 1, 2) 32
```

Iterator for broadcasting

broadcast(*arrays)

Produce an object that mimics broadcasting.

class `numpy.broadcast` (*arrays)

Produce an object that mimics broadcasting.

Parameters

in1, in2, ...
[array_like] Input parameters.

Attributes

index
current index in broadcasted result

iters
tuple of iterators along `self`'s "components."

nd
Number of dimensions of broadcasted result.

ndim
Number of dimensions of broadcasted result.

numiter
Number of iterators possessed by the broadcasted result.

shape
Shape of broadcasted result.

size
Total size of broadcasted result.

Methods

`reset()`

Reset the broadcasted result's iterator(s).

method

`broadcast.reset()`

Reset the broadcasted result's iterator(s).

Parameters**None****Returns****None**

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 3])
>>> y = np.array([[4], [5], [6]])
>>> b = np.broadcast(x, y)
>>> b.index
0
>>> next(b), next(b), next(b)
((1, 4), (2, 4), (3, 4))
>>> b.index
3
>>> b.reset()
>>> b.index
0
```

Returns**b**

[broadcast object] Broadcast the input parameters against one another, and return an object that encapsulates the result. Amongst others, it has `shape` and `nd` properties, and may be used as an iterator.

See also:*[broadcast_arrays](#)**[broadcast_to](#)**[broadcast_shapes](#)*

Examples

Manually adding two vectors, using broadcasting:

```
>>> import numpy as np
>>> x = np.array([[1], [2], [3]])
>>> y = np.array([4, 5, 6])
>>> b = np.broadcast(x, y)
```

```
>>> out = np.empty(b.shape)
>>> out.flat = [u+v for (u,v) in b]
>>> out
array([[5.,  6.,  7.],
       [6.,  7.,  8.],
       [7.,  8.,  9.]])
```

Compare against built-in broadcasting:

```
>>> x + y
array([[5,  6,  7],
       [6,  7,  8],
       [7,  8,  9]])
```

The general concept of broadcasting is also available from Python using the *broadcast* iterator. This object takes *N* objects as inputs and returns an iterator that returns tuples providing each of the input sequence elements in the broadcasted result.

```
>>> import numpy as np
>>> for val in np.broadcast([[1, 0], [2, 3]], [0, 1]):
...     print(val)
(np.int64(1), np.int64(0))
(np.int64(0), np.int64(1))
(np.int64(2), np.int64(0))
(np.int64(3), np.int64(1))
```

1.2.7 Masked arrays

Masked arrays are arrays that may have missing or invalid entries. The *numpy.ma* module provides a nearly work-alike replacement for numpy that supports data arrays with masks.

The *numpy.ma* module

Rationale

Masked arrays are arrays that may have missing or invalid entries. The *numpy.ma* module provides a nearly work-alike replacement for numpy that supports data arrays with masks.

What is a masked array?

In many circumstances, datasets can be incomplete or tainted by the presence of invalid data. For example, a sensor may have failed to record a data point, or recorded an invalid value. The `numpy.ma` module provides a convenient way to address this issue, by introducing masked arrays.

A masked array is the combination of a standard `numpy.ndarray` and a mask. A mask is either `nomask`, indicating that no value of the associated array is invalid, or an array of booleans that determines for each element of the associated array whether the value is valid or not. When an element of the mask is `False`, the corresponding element of the associated array is valid and is said to be unmasked. When an element of the mask is `True`, the corresponding element of the associated array is said to be masked (invalid).

The package ensures that masked entries are not used in computations.

As an illustration, let's consider the following dataset:

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> x = np.array([1, 2, 3, -1, 5])
```

We wish to mark the fourth entry as invalid. The easiest is to create a masked array:

```
>>> mx = ma.masked_array(x, mask=[0, 0, 0, 1, 0])
```

We can now compute the mean of the dataset, without taking the invalid data into account:

```
>>> mx.mean()
2.75
```

The `numpy.ma` module

The main feature of the `numpy.ma` module is the `MaskedArray` class, which is a subclass of `numpy.ndarray`. The class, its attributes and methods are described in more details in the [MaskedArray class](#) section.

The `numpy.ma` module can be used as an addition to `numpy`:

```
>>> import numpy as np
>>> import numpy.ma as ma
```

To create an array with the second element invalid, we would do:

```
>>> y = ma.array([1, 2, 3], mask = [0, 1, 0])
```

To create a masked array where all values close to `1.e20` are invalid, we would do:

```
>>> z = ma.masked_values([1.0, 1.e20, 3.0, 4.0], 1.e20)
```

For a complete discussion of creation methods for masked arrays please see section [Constructing masked arrays](#).

Using numpy.ma

Constructing masked arrays

There are several ways to construct a masked array.

- A first possibility is to directly invoke the `MaskedArray` class.
- A second possibility is to use the two masked array constructors, `array` and `masked_array`.

<code>array(data[, dtype, copy, order, mask, ...])</code>	An array class with possibly masked values.
<code>masked_array</code>	alias of <code>MaskedArray</code>

- A third option is to take the view of an existing array. In that case, the mask of the view is set to `nomask` if the array has no named fields, or an array of boolean with the same structure as the array otherwise.

```
>>> import numpy as np
>>> x = np.array([1, 2, 3])
>>> x.view(ma.MaskedArray)
masked_array(data=[1, 2, 3],
              mask=False,
              fill_value=999999)
>>> x = np.array([(1, 1.), (2, 2.)], dtype=[('a',int), ('b', float)])
>>> x.view(ma.MaskedArray)
masked_array(data=[(1, 1.0), (2, 2.0)],
              mask=[(False, False), (False, False)],
              fill_value=(999999, 1e+20),
              dtype=[('a', '<i8'), ('b', '<f8')])
```

- Yet another possibility is to use any of the following functions:

<code>asarray(a[, dtype, order])</code>	Convert the input to a masked array of the given data-type.
<code>asanyarray(a[, dtype, order])</code>	Convert the input to a masked array, conserving sub-classes.
<code>fix_invalid(a[, mask, copy, fill_value])</code>	Return input with invalid data masked and replaced by a fill value.
<code>masked_equal(x, value[, copy])</code>	Mask an array where equal to a given value.
<code>masked_greater(x, value[, copy])</code>	Mask an array where greater than a given value.
<code>masked_greater_equal(x, value[, copy])</code>	Mask an array where greater than or equal to a given value.
<code>masked_inside(x, v1, v2[, copy])</code>	Mask an array inside a given interval.
<code>masked_invalid(a[, copy])</code>	Mask an array where invalid values occur (NaNs or infs).
<code>masked_less(x, value[, copy])</code>	Mask an array where less than a given value.
<code>masked_less_equal(x, value[, copy])</code>	Mask an array where less than or equal to a given value.
<code>masked_not_equal(x, value[, copy])</code>	Mask an array where <i>not</i> equal to a given value.
<code>masked_object(x, value[, copy, shrink])</code>	Mask the array <i>x</i> where the data are exactly equal to value.
<code>masked_outside(x, v1, v2[, copy])</code>	Mask an array outside a given interval.
<code>masked_values(x, value[, rtol, atol, copy, ...])</code>	Mask using floating point equality.
<code>masked_where(condition, a[, copy])</code>	Mask an array where a condition is met.

Accessing the data

The underlying data of a masked array can be accessed in several ways:

- through the `data` attribute. The output is a view of the array as a `numpy.ndarray` or one of its subclasses, depending on the type of the underlying data at the masked array creation.
- through the `__array__` method. The output is then a `numpy.ndarray`.
- by directly taking a view of the masked array as a `numpy.ndarray` or one of its subclass (which is actually what using the `data` attribute does).
- by using the `getdata` function.

None of these methods is completely satisfactory if some entries have been marked as invalid. As a general rule, where a representation of the array is required without any masked entries, it is recommended to fill the array with the `filled` method.

Accessing the mask

The mask of a masked array is accessible through its `mask` attribute. We must keep in mind that a `True` entry in the mask indicates an *invalid* data.

Another possibility is to use the `getmask` and `getmaskarray` functions. `getmask(x)` outputs the mask of `x` if `x` is a masked array, and the special value `nomask` otherwise. `getmaskarray(x)` outputs the mask of `x` if `x` is a masked array. If `x` has no invalid entry or is not a masked array, the function outputs a boolean array of `False` with as many elements as `x`.

Accessing only the valid entries

To retrieve only the valid entries, we can use the inverse of the mask as an index. The inverse of the mask can be calculated with the `numpy.logical_not` function or simply with the `~` operator:

```
>>> import numpy as np
>>> x = ma.array([[1, 2], [3, 4]], mask=[[0, 1], [1, 0]])
>>> x[~x.mask]
masked_array(data=[1, 4],
             mask=[False, False],
             fill_value=999999)
```

Another way to retrieve the valid data is to use the `compressed` method, which returns a one-dimensional `ndarray` (or one of its subclasses, depending on the value of the `baseclass` attribute):

```
>>> x.compressed()
array([1, 4])
```

Note that the output of `compressed` is always 1D.

Modifying the mask

Masking an entry

The recommended way to mark one or several specific entries of a masked array as invalid is to assign the special value `masked` to them:

```
>>> x = ma.array([1, 2, 3])
>>> x[0] = ma.masked
>>> x
masked_array(data=[--, 2, 3],
             mask=[ True, False, False],
```

(continues on next page)

(continued from previous page)

```

        fill_value=999999)
>>> y = ma.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
>>> y[(0, 1, 2), (1, 2, 0)] = ma.masked
>>> y
masked_array(
  data=[[1, --, 3],
        [4, 5, --],
        [--, 8, 9]],
  mask=[[False,  True, False],
        [False, False,  True],
        [ True, False, False]],
  fill_value=999999)
>>> z = ma.array([1, 2, 3, 4])
>>> z[:-2] = ma.masked
>>> z
masked_array(data=[--, --, 3, 4],
             mask=[ True,  True, False, False],
             fill_value=999999)

```

A second possibility is to modify the `mask` directly, but this usage is discouraged.

Note: When creating a new masked array with a simple, non-structured datatype, the mask is initially set to the special value `nomask`, that corresponds roughly to the boolean `False`. Trying to set an element of `nomask` will fail with a `TypeError` exception, as a boolean does not support item assignment.

All the entries of an array can be masked at once by assigning `True` to the mask:

```

>>> import numpy.ma as ma
>>> x = ma.array([1, 2, 3], mask=[0, 0, 1])
>>> x.mask = True
>>> x
masked_array(data=[--, --, --],
             mask=[ True,  True,  True],
             fill_value=999999,
             dtype=int64)

```

Finally, specific entries can be masked and/or unmasked by assigning to the mask a sequence of booleans:

```

>>> x = ma.array([1, 2, 3])
>>> x.mask = [0, 1, 0]
>>> x
masked_array(data=[1, --, 3],
             mask=[False,  True, False],
             fill_value=999999)

```

Unmasking an entry

To unmask one or several specific entries, we can just assign one or several new valid values to them:

```
>>> import numpy.ma as ma
>>> x = ma.array([1, 2, 3], mask=[0, 0, 1])
>>> x
masked_array(data=[1, 2, --],
             mask=[False, False,  True],
             fill_value=999999)
>>> x[-1] = 5
>>> x
masked_array(data=[1, 2, 5],
             mask=[False, False, False],
             fill_value=999999)
```

Note: Unmasking an entry by direct assignment will silently fail if the masked array has a *hard* mask, as shown by the `hardmask` attribute. This feature was introduced to prevent overwriting the mask. To force the unmasking of an entry where the array has a hard mask, the mask must first be softened using the `soften_mask` method before the allocation. It can be re-hardened with `harden_mask` as follows:

```
>>> import numpy.ma as ma
>>> x = ma.array([1, 2, 3], mask=[0, 0, 1], hard_mask=True)
>>> x
masked_array(data=[1, 2, --],
             mask=[False, False,  True],
             fill_value=999999)
>>> x[-1] = 5
>>> x
masked_array(data=[1, 2, --],
             mask=[False, False,  True],
             fill_value=999999)
>>> x.soften_mask()
masked_array(data=[1, 2, --],
             mask=[False, False,  True],
             fill_value=999999)
>>> x[-1] = 5
>>> x
masked_array(data=[1, 2, 5],
             mask=[False, False, False],
             fill_value=999999)
>>> x.harden_mask()
masked_array(data=[1, 2, 5],
             mask=[False, False, False],
             fill_value=999999)
```

To unmask all masked entries of a masked array (provided the mask isn't a hard mask), the simplest solution is to assign the constant `nomask` to the mask:

```
>>> import numpy.ma as ma
>>> x = ma.array([1, 2, 3], mask=[0, 0, 1])
>>> x
masked_array(data=[1, 2, --],
             mask=[False, False,  True],
             fill_value=999999)
```

(continues on next page)

(continued from previous page)

```
>>> x.mask = ma.nomask
>>> x
masked_array(data=[1, 2, 3],
              mask=[False, False, False],
              fill_value=999999)
```

Indexing and slicing

As a *MaskedArray* is a subclass of *numpy.ndarray*, it inherits its mechanisms for indexing and slicing.

When accessing a single entry of a masked array with no named fields, the output is either a scalar (if the corresponding entry of the mask is *False*) or the special value *masked* (if the corresponding entry of the mask is *True*):

```
>>> import numpy.ma as ma
>>> x = ma.array([1, 2, 3], mask=[0, 0, 1])
>>> x[0]
1
>>> x[-1]
masked
>>> x[-1] is ma.masked
True
```

If the masked array has named fields, accessing a single entry returns a *numpy.void* object if none of the fields are masked, or a 0d masked array with the same dtype as the initial array if at least one of the fields is masked.

```
>>> import numpy.ma as ma
>>> y = ma.masked_array([(1,2), (3, 4)],
...                     mask=[(0, 0), (0, 1)],
...                     dtype=[('a', int), ('b', int)])
>>> y[0]
(1, 2)
>>> y[-1]
(3, --)
```

When accessing a slice, the output is a masked array whose *data* attribute is a view of the original data, and whose mask is either *nomask* (if there was no invalid entries in the original array) or a view of the corresponding slice of the original mask. The view is required to ensure propagation of any modification of the mask to the original.

```
>>> import numpy.ma as ma
>>> x = ma.array([1, 2, 3, 4, 5], mask=[0, 1, 0, 0, 1])
>>> mx = x[:3]
>>> mx
masked_array(data=[1, --, 3],
              mask=[False,  True, False],
              fill_value=999999)
>>> mx[1] = -1
>>> mx
masked_array(data=[1, -1, 3],
              mask=[False, False, False],
              fill_value=999999)
>>> x.mask
array([False, False, False, False,  True])
>>> x.data
array([ 1, -1,  3,  4,  5])
```

Accessing a field of a masked array with structured datatype returns a *MaskedArray*.

Operations on masked arrays

Arithmetic and comparison operations are supported by masked arrays. As much as possible, invalid entries of a masked array are not processed, meaning that the corresponding *data* entries *should* be the same before and after the operation.

Warning: We need to stress that this behavior may not be systematic, that masked data may be affected by the operation in some cases and therefore users should not rely on this data remaining unchanged.

The `numpy.ma` module comes with a specific implementation of most ufuncs. Unary and binary functions that have a validity domain (such as `log` or `divide`) return the `masked` constant whenever the input is masked or falls outside the validity domain:

```
>>> import numpy.ma as ma
>>> ma.log([-1, 0, 1, 2])
masked_array(data=[--, --, 0.0, 0.6931471805599453],
             mask=[ True,  True, False, False],
             fill_value=1e+20)
```

Masked arrays also support standard numpy ufuncs. The output is then a masked array. The result of a unary ufunc is masked wherever the input is masked. The result of a binary ufunc is masked wherever any of the input is masked. If the ufunc also returns the optional context output (a 3-element tuple containing the name of the ufunc, its arguments and its domain), the context is processed and entries of the output masked array are masked wherever the corresponding input fall outside the validity domain:

```
>>> import numpy.ma as ma
>>> x = ma.array([-1, 1, 0, 2, 3], mask=[0, 0, 0, 0, 1])
>>> np.log(x)
masked_array(data=[--, 0.0, --, 0.6931471805599453, --],
             mask=[ True, False,  True, False,  True],
             fill_value=1e+20)
```

Examples

Data with a given value representing missing data

Let's consider a list of elements, `x`, where values of `-9999.` represent missing data. We wish to compute the average value of the data and the vector of anomalies (deviations from the average):

```
>>> import numpy.ma as ma
>>> x = [0., 1., -9999., 3., 4.]
>>> mx = ma.masked_values(x, -9999.)
>>> print(mx.mean())
2.0
>>> print(mx - mx.mean())
[-2.0 -1.0 -- 1.0 2.0]
>>> print(mx.anom())
[-2.0 -1.0 -- 1.0 2.0]
```

Filling in the missing data

Suppose now that we wish to print that same data, but with the missing values replaced by the average value.

```
>>> import numpy.ma as ma
>>> mx = ma.masked_values(x, -9999.)
>>> print(mx.filled(mx.mean()))
[0.  1.  2.  3.  4.]
```

Numerical operations

Numerical operations can be easily performed without worrying about missing values, dividing by zero, square roots of negative numbers, etc.:

```
>>> import numpy.ma as ma
>>> x = ma.array([1., -1., 3., 4., 5., 6.], mask=[0,0,0,0,1,0])
>>> y = ma.array([1., 2., 0., 4., 5., 6.], mask=[0,0,0,0,0,1])
>>> print(ma.sqrt(x/y))
[1.0 -- -- 1.0 -- --]
```

Four values of the output are invalid: the first one comes from taking the square root of a negative number, the second from the division by zero, and the last two where the inputs were masked.

Ignoring extreme values

Let's consider an array `d` of floats between 0 and 1. We wish to compute the average of the values of `d` while ignoring any data outside the range `[0.2, 0.9]`:

```
>>> import numpy as np
>>> import numpy.ma as ma
>>> d = np.linspace(0, 1, 20)
>>> print(d.mean() - ma.masked_outside(d, 0.2, 0.9).mean())
-0.05263157894736836
```

Constants of the `numpy.ma` module

In addition to the `MaskedArray` class, the `numpy.ma` module defines several constants.

`numpy.ma.masked`

The `masked` constant is a special case of `MaskedArray`, with a float datatype and a null shape. It is used to test whether a specific entry of a masked array is masked, or to mask one or several entries of a masked array:

```
.. try_examples::
```

```
>>> import numpy as np
```

```
>>> x = np.ma.array([1, 2, 3], mask=[0, 1, 0])
>>> x[1] is np.ma.masked
True
>>> x[-1] = np.ma.masked
>>> x
masked_array(data=[1, --, --],
             mask=[False,  True,  True],
             fill_value=999999)
```

`numpy.ma.nomask`

Value indicating that a masked array has no invalid entry. `nomask` is used internally to speed up computations when the mask is not needed. It is represented internally as `np.False_`.

`numpy.ma.masked_print_option`

String used in lieu of missing data when a masked array is printed. By default, this string is `'--'`.

Use `set_display()` to change the default string. Example usage: `numpy.ma.masked_print_option.set_display('X')` replaces missing data with `'X'`.

The MaskedArray class

class `numpy.ma.MaskedArray`

A subclass of `ndarray` designed to manipulate numerical arrays with missing data.

An instance of `MaskedArray` can be thought as the combination of several elements:

- The *data*, as a regular `numpy.ndarray` of any shape or datatype (the data).
- A boolean *mask* with the same shape as the data, where a `True` value indicates that the corresponding element of the data is invalid. The special value `nomask` is also acceptable for arrays without named fields, and indicates that no data is invalid.
- A *fill_value*, a value that may be used to replace the invalid entries in order to return a standard `numpy.ndarray`.

Attributes and properties of masked arrays

See also:

Array Attributes

`ma.MaskedArray.data`

Returns the underlying data, as a view of the masked array.

If the underlying data is a subclass of `numpy.ndarray`, it is returned as such.

```
>>> x = np.ma.array(np.matrix([[1, 2], [3, 4]]), mask=[[0, 1], [1, 0]])
>>> x.data
matrix([[1, 2],
        [3, 4]])
```

The type of the data can be accessed through the `baseclass` attribute.

`ma.MaskedArray.mask`

Current mask.

`ma.MaskedArray.recordmask`

Get or set the mask of the array if it has no named fields. For structured arrays, returns an `ndarray` of booleans where entries are `True` if **all** the fields are masked, `False` otherwise:

```
>>> x = np.ma.array([(1, 1), (2, 2), (3, 3), (4, 4), (5, 5)],
...                  mask=[(0, 0), (1, 0), (1, 1), (0, 1), (0, 0)],
...                  dtype=[('a', int), ('b', int)])
>>> x.recordmask
array([False, False,  True, False, False])
```

`ma.MaskedArray.fill_value`

The filling value of the masked array is a scalar. When setting, `None` will set to a default based on the data type.

Examples

```
>>> import numpy as np
>>> for dt in [np.int32, np.int64, np.float64, np.complex128]:
...     np.ma.array([0, 1], dtype=dt).get_fill_value()
...
np.int64(9999999)
np.int64(9999999)
np.float64(1e+20)
np.complex128(1e+20+0j)
```

```
>>> x = np.ma.array([0, 1.], fill_value=-np.inf)
>>> x.fill_value
np.float64(-inf)
>>> x.fill_value = np.pi
>>> x.fill_value
np.float64(3.1415926535897931)
```

Reset to default:

```
>>> x.fill_value = None
>>> x.fill_value
np.float64(1e+20)
```

`ma.MaskedArray`.**baseclass**

Class of the underlying data (read-only).

`ma.MaskedArray`.**sharedmask**

Share status of the mask (read-only).

`ma.MaskedArray`.**hardmask**

Specifies whether values can be unmasked through assignments.

By default, assigning definite values to masked array entries will unmask them. When *hardmask* is True, the mask will not change through assignments.

See also:

`ma.MaskedArray.harden_mask`

`ma.MaskedArray.soften_mask`

Examples

```
>>> import numpy as np
>>> x = np.arange(10)
>>> m = np.ma.masked_array(x, x>5)
>>> assert not m.hardmask
```

Since *m* has a soft mask, assigning an element value unmask that element:

```
>>> m[8] = 42
>>> m
masked_array(data=[0, 1, 2, 3, 4, 5, --, --, 42, --],
             mask=[False, False, False, False, False, False, False,
                  True, True, False, True],
             fill_value=9999999)
```

After hardening, the mask is not affected by assignments:

```
>>> hardened = np.ma.harden_mask(m)
>>> assert m.hardmask and hardened is m
>>> m[:] = 23
>>> m
masked_array(data=[23, 23, 23, 23, 23, 23, --, --, 23, --],
             mask=[False, False, False, False, False, False, False, False,
                   True, True, False, True],
             fill_value=999999)
```

As *MaskedArray* is a subclass of *ndarray*, a masked array also inherits all the attributes and properties of a *ndarray* instance.

<i>MaskedArray.base</i>	Base object if memory is from some other object.
<i>MaskedArray.ctypes</i>	An object to simplify the interaction of the array with the ctypes module.
<i>MaskedArray.dtype</i>	Data-type of the array's elements.
<i>MaskedArray.flags</i>	Information about the memory layout of the array.
<i>MaskedArray.itemsize</i>	Length of one array element in bytes.
<i>MaskedArray.nbytes</i>	Total bytes consumed by the elements of the array.
<i>MaskedArray.ndim</i>	Number of array dimensions.
<i>MaskedArray.shape</i>	Tuple of array dimensions.
<i>MaskedArray.size</i>	Number of elements in the array.
<i>MaskedArray.strides</i>	Tuple of bytes to step in each dimension when traversing an array.
<i>MaskedArray.imag</i>	The imaginary part of the masked array.
<i>MaskedArray.real</i>	The real part of the masked array.
<i>MaskedArray.flat</i>	Return a flat iterator, or set a flattened version of self to value.
<i>MaskedArray.__array_priority__</i>	

attribute

`ma.MaskedArray.base`

Base object if memory is from some other object.

Examples

The base of an array that owns its memory is None:

```
>>> import numpy as np
>>> x = np.array([1, 2, 3, 4])
>>> x.base is None
True
```

Slicing creates a view, whose memory is shared with x:

```
>>> y = x[2:]
>>> y.base is x
True
```

attribute

`ma.MaskedArray.ctype`s

An object to simplify the interaction of the array with the ctypes module.

This attribute creates an object that makes it easier to use arrays when calling shared libraries with the ctypes module. The returned object has, among others, data, shape, and strides attributes (see Notes below) which themselves return ctypes objects that can be used as arguments to a shared library.

Parameters

None

Returns

c

[Python object] Possessing attributes data, shape, strides, etc.

See also:

`numpy.ctypeslib`

Notes

Below are the public attributes of this object which were documented in “Guide to NumPy” (we have omitted undocumented public attributes, as well as documented private attributes):

`_ctype`s.**data**

A pointer to the memory area of the array as a Python integer. This memory area may contain data that is not aligned, or not in correct byte-order. The memory area may not even be writeable. The array flags and data-type of this array should be respected when passing this attribute to arbitrary C-code to avoid trouble that can include Python crashing. User Beware! The value of this attribute is exactly the same as: `self._array_interface_['data'][0]`.

Note that unlike `data_as`, a reference won't be kept to the array: code like `ctypes.c_void_p((a + b).ctype`s.data) will result in a pointer to a deallocated array, and should be spelt `(a + b).ctype`s.data_as(ctypes.c_void_p)

`_ctype`s.**shape**

(`c_intp`*self.ndim): A ctypes array of length self.ndim where the basetype is the C-integer corresponding to `dtype('p')` on this platform (see `c_intp`). This base-type could be `ctypes.c_int`, `ctypes.c_long`, or `ctypes.c_longlong` depending on the platform. The ctypes array contains the shape of the underlying array.

`_ctype`s.**strides**

(`c_intp`*self.ndim): A ctypes array of length self.ndim where the basetype is the same as for the shape attribute. This ctypes array contains the strides information from the underlying array. This strides information is important for showing how many bytes must be jumped to get to the next element in the array.

`_ctype`s.**data_as** (*obj*)

Return the data pointer cast to a particular c-types object. For example, calling `self._as_parameter_` is equivalent to `self.data_as(ctypes.c_void_p)`. Perhaps you want to use the data as a pointer to a ctypes array of floating-point data: `self.data_as(ctypes.POINTER(ctypes.c_double))`.

The returned pointer will keep a reference to the array.

`_ctype`s.**shape_as** (*obj*)

Return the shape tuple as an array of some other c-types type. For example: `self.shape_as(ctypes.c_short)`.

`_ctypes.strides_as(obj)`

Return the strides tuple as an array of some other c-types type. For example: `self.strides_as(ctypes.c_longlong)`.

If the ctypes module is not available, then the ctypes attribute of array objects still returns something useful, but ctypes objects are not returned and errors may be raised instead. In particular, the object will still have the `as_parameter` attribute which will return an integer equal to the data attribute.

Examples

```
>>> import numpy as np
>>> import ctypes
>>> x = np.array([[0, 1], [2, 3]], dtype=np.int32)
>>> x
array([[0, 1],
       [2, 3]], dtype=int32)
>>> x.ctypes.data
31962608 # may vary
>>> x.ctypes.data_as(ctypes.POINTER(ctypes.c_uint32))
<__main__.LP_c_uint object at 0x7ff2fc1fc200> # may vary
>>> x.ctypes.data_as(ctypes.POINTER(ctypes.c_uint32)).contents
c_uint(0)
>>> x.ctypes.data_as(ctypes.POINTER(ctypes.c_uint64)).contents
c_ulong(4294967296)
>>> x.ctypes.shape
<numpy._core._internal.c_long_Array_2 object at 0x7ff2fc1fce60> # may vary
>>> x.ctypes.strides
<numpy._core._internal.c_long_Array_2 object at 0x7ff2fc1ff320> # may vary
```

property

property `ma.MaskedArray.dtype`

Data-type of the array's elements.

Warning: Setting `arr.dtype` is discouraged and may be deprecated in the future. Setting will replace the dtype without modifying the memory (see also [ndarray.view](#) and [ndarray.astype](#)).

Parameters

None

Returns

`d`

[numpy dtype object]

See also:

[ndarray.astype](#)

Cast the values contained in the array to a new data-type.

[ndarray.view](#)

Create a view of the same data but a different data-type.

[numpy.dtype](#)

Examples

```
>>> import numpy as np
>>> x = np.arange(4).reshape((2, 2))
>>> x
array([[0, 1],
       [2, 3]])
>>> x.dtype
dtype('int64')    # may vary (OS, bitness)
>>> isinstance(x.dtype, np.dtype)
True
```

attribute

`ma.MaskedArray.flags`

Information about the memory layout of the array.

Attributes

C_CONTIGUOUS (C)

The data is in a single, C-style contiguous segment.

F_CONTIGUOUS (F)

The data is in a single, Fortran-style contiguous segment.

OWNDATA (O)

The array owns the memory it uses or borrows it from another object.

WRITEABLE (W)

The data area can be written to. Setting this to False locks the data, making it read-only. A view (slice, etc.) inherits **WRITEABLE** from its base array at creation time, but a view of a writeable array may be subsequently locked while the base array remains writeable. (The opposite is not true, in that a view of a locked array may not be made writeable. However, currently, locking a base object does not lock any views that already reference it, so under that circumstance it is possible to alter the contents of a locked array via a previously created writeable view onto it.) Attempting to change a non-writeable array raises a `RuntimeError` exception.

ALIGNED (A)

The data and all elements are aligned appropriately for the hardware.

WRITEBACKIFCOPY (X)

This array is a copy of some other array. The C-API function `PyArray_ResolveWritebackIfCopy` must be called before deallocating to the base array will be updated with the contents of this array.

FNC

F_CONTIGUOUS and not **C_CONTIGUOUS**.

FORC

F_CONTIGUOUS or **C_CONTIGUOUS** (one-segment test).

BEHAVED (B)

ALIGNED and **WRITEABLE**.

CARRAY (CA)

BEHAVED and **C_CONTIGUOUS**.

FARRAY (FA)

BEHAVED and **F_CONTIGUOUS** and not **C_CONTIGUOUS**.

Notes

The `flags` object can be accessed dictionary-like (as in `a.flags['WRITEABLE']`), or by using lowercased attribute names (as in `a.flags.writeable`). Short flag names are only supported in dictionary access.

Only the `WRITEBACKIFCOPY`, `WRITEABLE`, and `ALIGNED` flags can be changed by the user, via direct assignment to the attribute or dictionary entry, or by calling `ndarray.setflags`.

The array flags cannot be set arbitrarily:

- `WRITEBACKIFCOPY` can only be set `False`.
- `ALIGNED` can only be set `True` if the data is truly aligned.
- `WRITEABLE` can only be set `True` if the array owns its own memory or the ultimate owner of the memory exposes a writeable buffer interface or is a string.

Arrays can be both C-style and Fortran-style contiguous simultaneously. This is clear for 1-dimensional arrays, but can also be true for higher dimensional arrays.

Even for contiguous arrays a stride for a given dimension `arr.strides[dim]` may be *arbitrary* if `arr.shape[dim] == 1` or the array has no elements. It does *not* generally hold that `self.strides[-1] == self.itemsize` for C-style contiguous arrays or `self.strides[0] == self.itemsize` for Fortran-style contiguous arrays is true.

attribute

`ma.MaskedArray.itemsize`

Length of one array element in bytes.

Examples

```
>>> import numpy as np
>>> x = np.array([1,2,3], dtype=np.float64)
>>> x.itemsize
8
>>> x = np.array([1,2,3], dtype=np.complex128)
>>> x.itemsize
16
```

attribute

`ma.MaskedArray.nbytes`

Total bytes consumed by the elements of the array.

See also:

`sys.getsizeof`

Memory consumed by the object itself without parents in case view. This does include memory consumed by non-element attributes.

Notes

Does not include memory consumed by non-element attributes of the array object.

Examples

```
>>> import numpy as np
>>> x = np.zeros((3,5,2), dtype=np.complex128)
>>> x.nbytes
480
>>> np.prod(x.shape) * x.itemsize
480
```

attribute

`ma.MaskedArray.ndim`

Number of array dimensions.

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 3])
>>> x.ndim
1
>>> y = np.zeros((2, 3, 4))
>>> y.ndim
3
```

property

property `ma.MaskedArray.shape`

Tuple of array dimensions.

The shape property is usually used to get the current shape of an array, but may also be used to reshape the array in-place by assigning a tuple of array dimensions to it. As with [`numpy.reshape`](#), one of the new shape dimensions can be -1, in which case its value is inferred from the size of the array and the remaining dimensions. Reshaping an array in-place will fail if a copy is required.

Warning: Setting `arr.shape` is deprecated and may be removed in the future. Using [`ndarray.reshape`](#) is the preferred approach.

See also:

[`numpy.shape`](#)

Equivalent getter function.

[`numpy.reshape`](#)

Function similar to setting shape.

[`ndarray.reshape`](#)

Method similar to setting shape.

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 3, 4])
>>> x.shape
(4,)
>>> y = np.zeros((2, 3, 4))
>>> y.shape
(2, 3, 4)
```

attribute

`ma.MaskedArray.size`

Number of elements in the array.

Equal to `np.prod(a.shape)`, i.e., the product of the array's dimensions.

Notes

`a.size` returns a standard arbitrary precision Python integer. This may not be the case with other methods of obtaining the same value (like the suggested `np.prod(a.shape)`, which returns an instance of `np.int_`), and may be relevant if the value is used further in calculations that may overflow a fixed size integer type.

Examples

```
>>> import numpy as np
>>> x = np.zeros((3, 5, 2), dtype=np.complex128)
>>> x.size
30
>>> np.prod(x.shape)
30
```

attribute

`ma.MaskedArray.strides`

Tuple of bytes to step in each dimension when traversing an array.

The byte offset of element $(i[0], i[1], \dots, i[n])$ in an array *a* is:

```
offset = sum(np.array(i) * a.strides)
```

A more detailed explanation of strides can be found in *The N-dimensional array (ndarray)*.

Warning: Setting `arr.strides` is discouraged and may be deprecated in the future. `numpy.lib.stride_tricks.as_strided` should be preferred to create a new view of the same data in a safer way.

See also:

`numpy.lib.stride_tricks.as_strided`

Notes

Imagine an array of 32-bit integers (each 4 bytes):

```
x = np.array([[0, 1, 2, 3, 4],
              [5, 6, 7, 8, 9]], dtype=np.int32)
```

This array is stored in memory as 40 bytes, one after the other (known as a contiguous block of memory). The strides of an array tell us how many bytes we have to skip in memory to move to the next position along a certain axis. For example, we have to skip 4 bytes (1 value) to move to the next column, but 20 bytes (5 values) to get to the same position in the next row. As such, the strides for the array *x* will be (20, 4).

Examples

```
>>> import numpy as np
>>> y = np.reshape(np.arange(2 * 3 * 4, dtype=np.int32), (2, 3, 4))
>>> y
array([[[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]],
       [[12, 13, 14, 15],
        [16, 17, 18, 19],
        [20, 21, 22, 23]]], dtype=np.int32)
>>> y.strides
(48, 16, 4)
>>> y[1, 1, 1]
np.int32(17)
>>> offset = sum(y.strides * np.array((1, 1, 1)))
>>> offset // y.itemsize
np.int64(17)
```

```
>>> x = np.reshape(np.arange(5*6*7*8, dtype=np.int32), (5, 6, 7, 8))
>>> x = x.transpose(2, 3, 1, 0)
>>> x.strides
(32, 4, 224, 1344)
>>> i = np.array([3, 5, 2, 2], dtype=np.int32)
>>> offset = sum(i * x.strides)
>>> x[3, 5, 2, 2]
np.int32(813)
>>> offset // x.itemsize
np.int64(813)
```

property

property `ma.MaskedArray.imag`

The imaginary part of the masked array.

This property is a view on the imaginary part of this *MaskedArray*.

See also:

[*real*](#)

Examples

```
>>> import numpy as np
>>> x = np.ma.array([1+1.j, -2j, 3.45+1.6j], mask=[False, True, False])
>>> x.imag
masked_array(data=[1.0, --, 1.6],
              mask=[False,  True, False],
              fill_value=1e+20)
```

property

property `ma.MaskedArray.real`

The real part of the masked array.

This property is a view on the real part of this *MaskedArray*.

See also:

[*imag*](#)

Examples

```
>>> import numpy as np
>>> x = np.ma.array([1+1.j, -2j, 3.45+1.6j], mask=[False, True, False])
>>> x.real
masked_array(data=[1.0, --, 3.45],
              mask=[False,  True, False],
              fill_value=1e+20)
```

property

property `ma.MaskedArray.flat`

Return a flat iterator, or set a flattened version of self to value.

attribute

`ma.MaskedArray.__array_priority__ = 15`

MaskedArray methods

See also:

[*Array methods*](#)

Conversion

<code>MaskedArray.__float__()</code>	Convert to float.
<code>MaskedArray.__int__()</code>	Convert to int.
<code>MaskedArray.view([dtype, type, fill_value])</code>	Return a view of the MaskedArray data.
<code>MaskedArray.astype(dtype[, order, casting, ...])</code>	Copy of the array, cast to a specified type.
<code>MaskedArray.byteswap([inplace])</code>	Swap the bytes of the array elements
<code>MaskedArray.compressed()</code>	Return all the non-masked data as a 1-D array.
<code>MaskedArray.filled([fill_value])</code>	Return a copy of self, with masked values filled with a given value.
<code>MaskedArray.tofile(fid[, sep, format])</code>	Save a masked array to a file in binary format.
<code>MaskedArray.toflex()</code>	Transforms a masked array into a flexible-type array.
<code>MaskedArray.tolist([fill_value])</code>	Return the data portion of the masked array as a hierarchical Python list.
<code>MaskedArray.torecords()</code>	Transforms a masked array into a flexible-type array.
<code>MaskedArray.tobytes([fill_value, order])</code>	Return the array data as a string containing the raw bytes in the array.

method

`ma.MaskedArray.__float__()`
Convert to float.

method

`ma.MaskedArray.__int__()`
Convert to int.

method

`ma.MaskedArray.view(dtype=None, type=None, fill_value=None)`
Return a view of the MaskedArray data.

Parameters

dtype

[data-type or ndarray sub-class, optional] Data-type descriptor of the returned view, e.g., float32 or int16. The default, None, results in the view having the same data-type as *a*. As with `ndarray.view`, dtype can also be specified as an ndarray sub-class, which then specifies the type of the returned object (this is equivalent to setting the `type` parameter).

type

[Python type, optional] Type of the returned view, either ndarray or a subclass. The default None results in type preservation.

fill_value

[scalar, optional] The value to use for invalid entries (None by default). If None, then this argument is inferred from the passed *dtype*, or in its absence the original array, as discussed in the notes below.

See also:

`numpy.ndarray.view`

Equivalent method on ndarray object.

Notes

`a.view()` is used two different ways:

`a.view(some_dtype)` or `a.view(dtype=some_dtype)` constructs a view of the array's memory with a different data-type. This can cause a reinterpretation of the bytes of memory.

`a.view(ndarray_subclass)` or `a.view(type=ndarray_subclass)` just returns an instance of *ndarray_subclass* that looks at the same array (same shape, dtype, etc.) This does not cause a reinterpretation of the memory.

If *fill_value* is not specified, but *dtype* is specified (and is not an ndarray sub-class), the *fill_value* of the MaskedArray will be reset. If neither *fill_value* nor *dtype* are specified (or if *dtype* is an ndarray sub-class), then the fill value is preserved. Finally, if *fill_value* is specified, but *dtype* is not, the fill value is set to the specified value.

For `a.view(some_dtype)`, if *some_dtype* has a different number of bytes per entry than the previous dtype (for example, converting a regular array to a structured array), then the behavior of the view cannot be predicted just from the superficial appearance of *a* (shown by `print(a)`). It also depends on exactly how *a* is stored in memory. Therefore if *a* is C-ordered versus fortran-ordered, versus defined as a slice or transpose, etc., the view may give different results.

method

`ma.MaskedArray.astype(dtype, order='K', casting='unsafe', subok=True, copy=True)`

Copy of the array, cast to a specified type.

Parameters

dtype

[str or dtype] Typecode or data-type to which the array is cast.

order

[{'C', 'F', 'A', 'K'}, optional] Controls the memory layout order of the result. 'C' means C order, 'F' means Fortran order, 'A' means 'F' order if all the arrays are Fortran contiguous, 'C' order otherwise, and 'K' means as close to the order the array elements appear in memory as possible. Default is 'K'.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'same_value', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility.

- 'no' means the data types should not be cast at all.
- 'equiv' means only byte-order changes are allowed.
- 'safe' means only casts which can preserve values are allowed.
- 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed.
- 'unsafe' means any data conversions may be done.
- 'same_value' means any data conversions may be done, but the values must not change, including rounding of floats or overflow of ints

New in version 2.4: Support for 'same_value' was added.

subok

[bool, optional] If True, then sub-classes will be passed-through (default), otherwise the returned array will be forced to be a base-class array.

copy

[bool, optional] By default, `astype` always returns a newly allocated array. If this is set to false,

and the *dtype*, *order*, and *subok* requirements are satisfied, the input array is returned instead of a copy.

Returns

arr_t

[ndarray] Unless *copy* is False and the other conditions for returning the input array are satisfied (see description for *copy* input parameter), *arr_t* is a new array of the same shape as the input array, with dtype, order given by *dtype*, *order*.

Raises

ComplexWarning

When casting from complex to float or int. To avoid this, one should use `a.real.astype(t)`.

ValueError

When casting using 'same_value' and the values change or would overflow

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 2.5])
>>> x
array([1. ,  2. ,  2.5])
```

```
>>> x.astype(np.int_)
array([1, 2, 2])
```

```
>>> x.astype(np.int_, casting="same_value")
Traceback (most recent call last):
...
ValueError: could not cast 'same_value' double to long
```

```
>>> x[:2].astype(np.int_, casting="same_value")
array([1, 2])
```

method

`ma.MaskedArray.byteswap(inplace=False)`

Swap the bytes of the array elements

Toggle between low-endian and big-endian data representation by returning a byteswapped array, optionally swapped in-place. Arrays of byte-strings are not swapped. The real and imaginary parts of a complex number are swapped individually.

Parameters

inplace

[bool, optional] If True, swap bytes in-place, default is False.

Returns

out

[ndarray] The byteswapped array. If *inplace* is True, this is a view to self.

Examples

```
>>> import numpy as np
>>> A = np.array([1, 256, 8755], dtype=np.int16)
>>> list(map(hex, A))
['0x1', '0x100', '0x2233']
>>> A.byteswap(inplace=True)
array([ 256,      1, 13090], dtype=int16)
>>> list(map(hex, A))
['0x100', '0x1', '0x3322']
```

Arrays of byte-strings are not swapped

```
>>> A = np.array([b'ceg', b'fac'])
>>> A.byteswap()
array([b'ceg', b'fac'], dtype='<S3')
```

`A.view(A.dtype.newbyteorder()).byteswap()` produces an array with the same values but different representation in memory

```
>>> A = np.array([1, 2, 3], dtype=np.int64)
>>> A.view(np.uint8)
array([1, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0, 0, 0, 3, 0, 0, 0, 0, 0,
       0, 0], dtype=uint8)
>>> A.view(A.dtype.newbyteorder()).byteswap(inplace=True)
array([1, 2, 3], dtype='>i8')
>>> A.view(np.uint8)
array([0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 2, 0, 0, 0, 0, 0,
       0, 3], dtype=uint8)
```

method

`ma.MaskedArray.toflex()`

Transforms a masked array into a flexible-type array.

The flexible type array that is returned will have two fields:

- the `_data` field stores the `_data` part of the array.
- the `_mask` field stores the `_mask` part of the array.

Parameters

None

Returns

record

[ndarray] A new flexible-type *ndarray* with two fields: the first element containing a value, the second element containing the corresponding mask boolean. The returned record shape matches `self.shape`.

Notes

A side-effect of transforming a masked array into a flexible *ndarray* is that meta information (*fill_value*, ...) will be lost.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[1,2,3],[4,5,6],[7,8,9]], mask=[0] + [1,0]*4)
>>> x
masked_array(
  data=[[1, --, 3],
        [--, 5, --],
        [7, --, 9]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=999999)
>>> x.toflex()
array([(1, False), (2,  True), (3, False)],
      [(4,  True), (5, False), (6,  True)],
      [(7, False), (8,  True), (9, False)]],
      dtype=[('_data', '<i8'), ('_mask', '?')])
```

Shape manipulation

For reshape, resize, and transpose, the single tuple argument may be replaced with *n* integers which will be interpreted as an *n*-tuple.

<i>MaskedArray.flatten</i> ([order])	Return a copy of the array collapsed into one dimension.
<i>MaskedArray.ravel</i> ([order])	Returns a 1D version of self, as a view.
<i>MaskedArray.reshape</i> (*s, **kwargs)	Returns a reshaped masked array without changing its data.
<i>MaskedArray.resize</i> (newshape[, refcheck, order])	
<i>MaskedArray.squeeze</i> ([axis])	Remove axes of length one from <i>a</i> .
<i>MaskedArray.swapaxes</i> (axis1, axis2, /)	Return a view of the array with <i>axis1</i> and <i>axis2</i> interchanged.
<i>MaskedArray.transpose</i> (*axes)	Returns a view of the array with axes transposed.
<i>MaskedArray.T</i>	View of the transposed array.

property

property *ma.MaskedArray.T*

View of the transposed array.

Same as *self.transpose()*.

See also:

transpose

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> a
array([[1, 2],
       [3, 4]])
>>> a.T
array([[1, 3],
       [2, 4]])
```

```
>>> a = np.array([1, 2, 3, 4])
>>> a
array([1, 2, 3, 4])
>>> a.T
array([1, 2, 3, 4])
```

Item selection and manipulation

For array methods that take an `axis` keyword, it defaults to `None`. If `axis` is `None`, then the array is treated as a 1-D array. Any other value for `axis` represents the dimension along which the operation should proceed.

<code>MaskedArray.argmax([axis, fill_value, out, ...])</code>	Returns array of indices of the maximum values along the given axis.
<code>MaskedArray.argmin([axis, fill_value, out, ...])</code>	Return array of indices to the minimum values along the given axis.
<code>MaskedArray.argsort([axis, kind, order, ...])</code>	Return an ndarray of indices that sort the array along the specified axis.
<code>MaskedArray.choose(choices[, out, mode])</code>	Use an index array to construct a new array from a set of choices.
<code>MaskedArray.compress(condition[, axis, out])</code>	Return <i>a</i> where condition is <code>True</code> .
<code>MaskedArray.diagonal([offset, axis1, axis2])</code>	Return specified diagonals.
<code>MaskedArray.fill(value)</code>	Fill the array with a scalar value.
<code>MaskedArray.item(*args)</code>	Copy an element of an array to a standard Python scalar and return it.
<code>MaskedArray.nonzero()</code>	Return the indices of unmasked elements that are not zero.
<code>MaskedArray.put(indices, values[, mode])</code>	Set storage-indexed locations to corresponding values.
<code>MaskedArray.repeat(repeats[, axis])</code>	Repeat elements of an array.
<code>MaskedArray.searchsorted(v[, side, sorter])</code>	Find indices where elements of <i>v</i> should be inserted in <i>a</i> to maintain order.
<code>MaskedArray.sort([axis, kind, order, ...])</code>	Sort the array, in-place
<code>MaskedArray.take(indices[, axis, out, mode])</code>	Take elements from a masked array along an axis.

method

`ma.MaskedArray.choose (choices, out=None, mode='raise')`

Use an index array to construct a new array from a set of choices.

Refer to `numpy.choose` for full documentation.

See also:

`numpy.choose`

equivalent function

method

`ma.MaskedArray.compress(condition, axis=None, out=None)`

Return *a* where condition is True.

If condition is a *MaskedArray*, missing values are considered as False.

Parameters

condition

[var] Boolean 1-d array selecting which entries to return. If `len(condition)` is less than the size of *a* along the axis, then output is truncated to length of condition array.

axis

[{None, int}, optional] Axis along which the operation must be performed.

out

[{None, ndarray}, optional] Alternative output array in which to place the result. It must have the same shape as the expected output but the type will be cast if necessary.

Returns

result

[MaskedArray] A *MaskedArray* object.

Notes

Please note the difference with *compressed* ! The output of *compress* has a mask, the output of *compressed* does not.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[1,2,3],[4,5,6],[7,8,9]], mask=[0] + [1,0]*4)
>>> x
masked_array(
  data=[[1, --, 3],
        [--, 5, --],
        [7, --, 9]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=999999)
>>> x.compress([1, 0, 1])
masked_array(data=[1, 3],
             mask=[False, False],
             fill_value=999999)
```

```
>>> x.compress([1, 0, 1], axis=1)
masked_array(
  data=[[1, 3],
        [--, --],
        [7, 9]],
  mask=[[False, False],
        [ True,  True],
        [False, False]],
  fill_value=999999)
```

method

`ma.MaskedArray.diagonal (offset=0, axis1=0, axis2=1)`

Return specified diagonals. In NumPy 1.9 the returned array is a read-only view instead of a copy as in previous NumPy versions. In a future version the read-only restriction will be removed.

Refer to [*numpy.diagonal*](#) for full documentation.

See also:

[*numpy.diagonal*](#)
equivalent function

method

`ma.MaskedArray.fill (value)`

Fill the array with a scalar value.

Parameters

value

[scalar] All elements of *a* will be assigned this value.

Examples

```
>>> import numpy as np
>>> a = np.array([1, 2])
>>> a.fill(0)
>>> a
array([0, 0])
>>> a = np.empty(2)
>>> a.fill(1)
>>> a
array([1., 1.]
```

Fill expects a scalar value and always behaves the same as assigning to a single array element. The following is a rare example where this distinction is important:

```
>>> a = np.array([None, None], dtype=np.object_)
>>> a[0] = np.array(3)
>>> a
array([array(3), None], dtype=object)
>>> a.fill(np.array(3))
>>> a
array([array(3), array(3)], dtype=object)
```

Where other forms of assignments will unpack the array being assigned:

```
>>> a[...] = np.array(3)
>>> a
array([3, 3], dtype=object)
```

method

`ma.MaskedArray.item (*args)`

Copy an element of an array to a standard Python scalar and return it.

Parameters

***args**

[Arguments (variable number and type)]

- `none`: in this case, the method only works for arrays with one element (`a.size == 1`), which element is copied into a standard Python scalar object and returned.
- `int_type`: this argument is interpreted as a flat index into the array, specifying which element to copy and return.
- `tuple of int_types`: functions as does a single `int_type` argument, except that the argument is interpreted as an nd-index into the array.

Returns**z**

[Standard Python scalar object] A copy of the specified element of the array as a suitable Python scalar

Notes

When the data type of *a* is `longdouble` or `clongdouble`, `item()` returns a scalar array object because there is no available Python scalar that would not lose information. Void arrays return a buffer object for `item()`, unless fields are defined, in which case a tuple is returned.

`item` is very similar to `a[args]`, except, instead of an array scalar, a standard Python scalar is returned. This can be useful for speeding up access to elements of the array and doing arithmetic on elements of the array using Python's optimized math.

Examples

```
>>> import numpy as np
>>> np.random.seed(123)
>>> x = np.random.randint(9, size=(3, 3))
>>> x
array([[2, 2, 6],
       [1, 3, 6],
       [1, 0, 1]])
>>> x.item(3)
1
>>> x.item(7)
0
>>> x.item((0, 1))
2
>>> x.item((2, 2))
1
```

For an array with object dtype, elements are returned as-is.

```
>>> a = np.array([np.int64(1)], dtype=np.object_)
>>> a.item() #return np.int64
np.int64(1)
```

method

`ma.MaskedArray.put` (*indices, values, mode='raise'*)

Set storage-indexed locations to corresponding values.

Sets `self._data.flat[n] = values[n]` for each `n` in `indices`. If `values` is shorter than `indices` then it will repeat. If `values` has some masked values, the initial mask is updated in consequence, else the corresponding values are unmasked.

Parameters

indices

[1-D array_like] Target indices, interpreted as integers.

values

[array_like] Values to place in `self._data` copy at target indices.

mode

[{'raise', 'wrap', 'clip'}, optional] Specifies how out-of-bounds indices will behave. 'raise' : raise an error. 'wrap' : wrap around. 'clip' : clip to the range.

Notes

`values` can be a scalar or length 1 array.

Examples

```
>>> import numpy as np
>>> x = np.ma.array([[1,2,3],[4,5,6],[7,8,9]], mask=[0] + [1,0]*4)
>>> x
masked_array(
  data=[[1, --, 3],
        [--, 5, --],
        [7, --, 9]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=999999)
>>> x.put([0,4,8],[10,20,30])
>>> x
masked_array(
  data=[[10, --, 3],
        [--, 20, --],
        [7, --, 30]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=999999)
```

```
>>> x.put(4,999)
>>> x
masked_array(
  data=[[10, --, 3],
        [--, 999, --],
        [7, --, 30]],
  mask=[[False,  True, False],
        [ True, False,  True],
        [False,  True, False]],
  fill_value=999999)
```

method

`ma.MaskedArray.repeat` (*repeats*, *axis=None*)

Repeat elements of an array.

Refer to [`numpy.repeat`](#) for full documentation.

See also:

[`numpy.repeat`](#)

equivalent function

method

`ma.MaskedArray.searchsorted` (*v*, *side='left'*, *sorter=None*)

Find indices where elements of *v* should be inserted in *a* to maintain order.

For full documentation, see [`numpy.searchsorted`](#).

See also:

[`numpy.searchsorted`](#)

equivalent function

method

`ma.MaskedArray.take` (*indices*, *axis=None*, *out=None*, *mode='raise'*)

Take elements from a masked array along an axis.

This function does the same thing as “fancy” indexing (indexing arrays using arrays) for masked arrays. It can be easier to use if you need elements along a given axis.

Parameters

a

[masked_array] The source masked array.

indices

[array_like] The indices of the values to extract. Also allow scalars for indices.

axis

[int, optional] The axis over which to select values. By default, the flattened input array is used.

out

[MaskedArray, optional] If provided, the result will be placed in this array. It should be of the appropriate shape and dtype. Note that *out* is always buffered if *mode='raise'*; use other modes for better performance.

mode

[{'raise', 'wrap', 'clip'}, optional] Specifies how out-of-bounds indices will behave.

- 'raise' – raise an error (default)
- 'wrap' – wrap around
- 'clip' – clip to the range

'clip' mode means that all indices that are too large are replaced by the index that addresses the last element along that axis. Note that this disables indexing with negative numbers.

Returns

out

[MaskedArray] The returned array has the same type as *a*.

See also:

numpy.take

Equivalent function for ndarrays.

compress

Take elements using a boolean mask.

take_along_axis

Take elements by matching the array and the index arrays.

Notes

This function behaves similarly to *numpy.take*, but it handles masked values. The mask is retained in the output array, and masked values in the input array remain masked in the output.

Examples

```
>>> import numpy as np
>>> a = np.ma.array([4, 3, 5, 7, 6, 8], mask=[0, 0, 1, 0, 1, 0])
>>> indices = [0, 1, 4]
>>> np.ma.take(a, indices)
masked_array(data=[4, 3, --],
             mask=[False, False,  True],
             fill_value=999999)
```

When *indices* is not one-dimensional, the output also has these dimensions:

```
>>> np.ma.take(a, [[0, 1], [2, 3]])
masked_array(data=[[4, 3],
                  [--, 7]],
             mask=[[False, False],
                  [ True, False]],
             fill_value=999999)
```

Pickling and copy

<i>MaskedArray.copy</i> ([order])	Return a copy of the array.
<i>MaskedArray.dump</i> (file)	Dump a pickle of the array to the specified file.
<i>MaskedArray.dumps</i> ()	Returns the pickle of the array as a string.

method

`ma.MaskedArray.dump(file)`

Dump a pickle of the array to the specified file. The array can be read back with `pickle.load` or `numpy.load`.

Parameters

file

[str or Path] A string naming the dump file.

method

`ma.MaskedArray.dumps()`

Returns the pickle of the array as a string. `pickle.loads` will convert the string back to an array.

Parameters

None

Calculations

<code>MaskedArray.all([axis, out, keepdims])</code>	Returns True if all elements evaluate to True.
<code>MaskedArray.anom([axis, dtype])</code>	Compute the anomalies (deviations from the arithmetic mean) along the given axis.
<code>MaskedArray.any([axis, out, keepdims])</code>	Returns True if any of the elements of <i>a</i> evaluate to True.
<code>MaskedArray.clip([min, max, out])</code>	Return an array whose values are limited to <code>[min, max]</code> .
<code>MaskedArray.conj()</code>	Complex-conjugate all elements.
<code>MaskedArray.conjugate()</code>	Return the complex conjugate, element-wise.
<code>MaskedArray.cumprod([axis, dtype, out])</code>	Return the cumulative product of the array elements over the given axis.
<code>MaskedArray.cumsum([axis, dtype, out])</code>	Return the cumulative sum of the array elements over the given axis.
<code>MaskedArray.max([axis, out, fill_value, ...])</code>	Return the maximum along a given axis.
<code>MaskedArray.mean([axis, dtype, out, keepdims])</code>	Returns the average of the array elements along given axis.
<code>MaskedArray.min([axis, out, fill_value, ...])</code>	Return the minimum along a given axis.
<code>MaskedArray.prod([axis, dtype, out, keepdims])</code>	Return the product of the array elements over the given axis.
<code>MaskedArray.product([axis, dtype, out, keepdims])</code>	Return the product of the array elements over the given axis.
<code>MaskedArray.ptp([axis, out, fill_value, ...])</code>	Return (maximum - minimum) along the given dimension (i.e. peak-to-peak value).
<code>MaskedArray.round([decimals, out])</code>	Return each element rounded to the given number of decimals.
<code>MaskedArray.std([axis, dtype, out, ddof, ...])</code>	Returns the standard deviation of the array elements along given axis.
<code>MaskedArray.sum([axis, dtype, out, keepdims])</code>	Return the sum of the array elements over the given axis.
<code>MaskedArray.trace([offset, axis1, axis2, ...])</code>	Return the sum along diagonals of the array.
<code>MaskedArray.var([axis, dtype, out, ddof, ...])</code>	Compute the variance along the specified axis.

method

`ma.MaskedArray.conj()`

Complex-conjugate all elements.

Refer to `numpy.conjugate` for full documentation.

See also:

`numpy.conjugate`
equivalent function

method

`ma.MaskedArray.conjugate()`

Return the complex conjugate, element-wise.

Refer to `numpy.conjugate` for full documentation.

See also:

[`numpy.conjugate`](#)
equivalent function

method

`ma.MaskedArray.product` (*axis=None, dtype=None, out=None, keepdims=<no value>*)

Return the product of the array elements over the given axis.

Masked elements are set to 1 internally for computation.

Refer to [`numpy.prod`](#) for full documentation.

See also:

[`numpy.ndarray.prod`](#)
corresponding function for ndarrays

[`numpy.prod`](#)
equivalent function

Notes

Arithmetic is modular when using integer types, and no error is raised on overflow.

Arithmetic and comparison operations

Comparison operators:

<code>MaskedArray.__lt__(other)</code>	Return self<value.
<code>MaskedArray.__le__(other)</code>	Return self<=value.
<code>MaskedArray.__gt__(other)</code>	Return self>value.
<code>MaskedArray.__ge__(other)</code>	Return self>=value.
<code>MaskedArray.__eq__(other)</code>	Check whether other equals self elementwise.
<code>MaskedArray.__ne__(other)</code>	Check whether other does not equal self elementwise.

method

`ma.MaskedArray.__lt__(other)`

Return self<value.

method

`ma.MaskedArray.__le__(other)`

Return self<=value.

method

`ma.MaskedArray.__gt__(other)`

Return self>value.

method

`ma.MaskedArray.__ge__(other)`

Return self>=value.

method

`ma.MaskedArray.__eq__(other)`

Check whether other equals self elementwise.

When either of the elements is masked, the result is masked as well, but the underlying boolean data are still set, with self and other considered equal if both are masked, and unequal otherwise.

For structured arrays, all fields are combined, with masked values ignored. The result is masked if all fields were masked, with self and other considered equal only if both were fully masked.

method

`ma.MaskedArray.__ne__(other)`

Check whether other does not equal self elementwise.

When either of the elements is masked, the result is masked as well, but the underlying boolean data are still set, with self and other considered equal if both are masked, and unequal otherwise.

For structured arrays, all fields are combined, with masked values ignored. The result is masked if all fields were masked, with self and other considered equal only if both were fully masked.

Truth value of an array (`bool()`):

<code>MaskedArray.__bool__()</code>	True if self else False
-------------------------------------	-------------------------

method

`ma.MaskedArray.__bool__()`

True if self else False

Arithmetic:

<i>MaskedArray.__abs__(self)</i>	
<i>MaskedArray.__add__(other)</i>	Add self to other, and return a new masked array.
<i>MaskedArray.__radd__(other)</i>	Add other to self, and return a new masked array.
<i>MaskedArray.__sub__(other)</i>	Subtract other from self, and return a new masked array.
<i>MaskedArray.__rsub__(other)</i>	Subtract self from other, and return a new masked array.
<i>MaskedArray.__mul__(other)</i>	Multiply self by other, and return a new masked array.
<i>MaskedArray.__rmul__(other)</i>	Multiply other by self, and return a new masked array.
<i>MaskedArray.__truediv__(other)</i>	Divide other into self, and return a new masked array.
<i>MaskedArray.__rtruediv__(other)</i>	Divide self into other, and return a new masked array.
<i>MaskedArray.__floordiv__(other)</i>	Divide other into self, and return a new masked array.
<i>MaskedArray.__rfloordiv__(other)</i>	Divide self into other, and return a new masked array.
<i>MaskedArray.__mod__(value, /)</i>	Return self%value.
<i>MaskedArray.__rmod__(value, /)</i>	Return value%self.
<i>MaskedArray.__divmod__(value, /)</i>	Return divmod(self, value).
<i>MaskedArray.__rdivmod__(value, /)</i>	Return divmod(value, self).
<i>MaskedArray.__pow__(other)</i>	Raise self to the power other, masking the potential NaNs/Infs
<i>MaskedArray.__rpow__(other)</i>	Raise other to the power self, masking the potential NaNs/Infs
<i>MaskedArray.__lshift__(value, /)</i>	Return self<<value.
<i>MaskedArray.__rlshift__(value, /)</i>	Return value<<self.
<i>MaskedArray.__rshift__(value, /)</i>	Return self>>value.
<i>MaskedArray.__rrshift__(value, /)</i>	Return value>>self.
<i>MaskedArray.__and__(value, /)</i>	Return self&value.
<i>MaskedArray.__rand__(value, /)</i>	Return value&self.
<i>MaskedArray.__or__(value, /)</i>	Return self value.
<i>MaskedArray.__ror__(value, /)</i>	Return value self.
<i>MaskedArray.__xor__(value, /)</i>	Return self^value.
<i>MaskedArray.__rxor__(value, /)</i>	Return value^self.

method

ma.MaskedArray.**__abs__**(self)

method

ma.MaskedArray.**__add__**(other)

Add self to other, and return a new masked array.

method

ma.MaskedArray.**__radd__**(other)

Add other to self, and return a new masked array.

method

ma.MaskedArray.**__sub__**(other)

Subtract other from self, and return a new masked array.

method

ma.MaskedArray.**__rsub__**(other)

Subtract self from other, and return a new masked array.

method

`ma.MaskedArray.__mul__ (other)`

Multiply self by other, and return a new masked array.

method

`ma.MaskedArray.__rmul__ (other)`

Multiply other by self, and return a new masked array.

method

`ma.MaskedArray.__truediv__ (other)`

Divide other into self, and return a new masked array.

method

`ma.MaskedArray.__rtruediv__ (other)`

Divide self into other, and return a new masked array.

method

`ma.MaskedArray.__floordiv__ (other)`

Divide other into self, and return a new masked array.

method

`ma.MaskedArray.__rfloordiv__ (other)`

Divide self into other, and return a new masked array.

method

`ma.MaskedArray.__mod__ (value, /)`

Return self%value.

method

`ma.MaskedArray.__rmod__ (value, /)`

Return value%self.

method

`ma.MaskedArray.__divmod__ (value, /)`

Return divmod(self, value).

method

`ma.MaskedArray.__rdivmod__ (value, /)`

Return divmod(value, self).

method

`ma.MaskedArray.__pow__ (other)`

Raise self to the power other, masking the potential NaNs/Infs

method

`ma.MaskedArray.__rpow__ (other)`

Raise other to the power self, masking the potential NaNs/Infs

method

`ma.MaskedArray.__lshift__(value, /)`

Return `self<<value`.

method

`ma.MaskedArray.__rlshift__(value, /)`

Return `value<<self`.

method

`ma.MaskedArray.__rshift__(value, /)`

Return `self>>value`.

method

`ma.MaskedArray.__rrshift__(value, /)`

Return `value>>self`.

method

`ma.MaskedArray.__and__(value, /)`

Return `self&value`.

method

`ma.MaskedArray.__rand__(value, /)`

Return `value&self`.

method

`ma.MaskedArray.__or__(value, /)`

Return `self|value`.

method

`ma.MaskedArray.__ror__(value, /)`

Return `value|self`.

method

`ma.MaskedArray.__xor__(value, /)`

Return `self^value`.

method

`ma.MaskedArray.__rxor__(value, /)`

Return `value^self`.

Arithmetic, in-place:

<code>MaskedArray.__iadd__(other)</code>	Add other to self in-place.
<code>MaskedArray.__isub__(other)</code>	Subtract other from self in-place.
<code>MaskedArray.__imul__(other)</code>	Multiply self by other in-place.
<code>MaskedArray.__itruediv__(other)</code>	True divide self by other in-place.
<code>MaskedArray.__ifloordiv__(other)</code>	Floor divide self by other in-place.
<code>MaskedArray.__imod__(value, /)</code>	Return self%=value.
<code>MaskedArray.__ipow__(other)</code>	Raise self to the power other, in place.
<code>MaskedArray.__ilshift__(value, /)</code>	Return self<<=value.
<code>MaskedArray.__irshift__(value, /)</code>	Return self>>=value.
<code>MaskedArray.__iand__(value, /)</code>	Return self&=value.
<code>MaskedArray.__ior__(value, /)</code>	Return self =value.
<code>MaskedArray.__ixor__(value, /)</code>	Return self^=value.

method

`ma.MaskedArray.__iadd__(other)`

Add other to self in-place.

method

`ma.MaskedArray.__isub__(other)`

Subtract other from self in-place.

method

`ma.MaskedArray.__imul__(other)`

Multiply self by other in-place.

method

`ma.MaskedArray.__itruediv__(other)`

True divide self by other in-place.

method

`ma.MaskedArray.__ifloordiv__(other)`

Floor divide self by other in-place.

method

`ma.MaskedArray.__imod__(value, /)`

Return self%=value.

method

`ma.MaskedArray.__ipow__(other)`

Raise self to the power other, in place.

method

`ma.MaskedArray.__ilshift__(value, /)`

Return self<<=value.

method

`ma.MaskedArray.__irshift__(value, /)`

Return `self>>=value`.

method

`ma.MaskedArray.__iand__(value, /)`

Return `self&=value`.

method

`ma.MaskedArray.__ior__(value, /)`

Return `self|=value`.

method

`ma.MaskedArray.__ixor__(value, /)`

Return `self^=value`.

Representation

<code>MaskedArray.__repr__()</code>	Literal string representation.
<code>MaskedArray.__str__()</code>	Return <code>str(self)</code> .
<code>MaskedArray.ids()</code>	Return the addresses of the data and mask areas.
<code>MaskedArray.iscontiguous()</code>	Return a boolean indicating whether the data is contiguous.

method

`ma.MaskedArray.__repr__()`

Literal string representation.

method

`ma.MaskedArray.__str__()`

Return `str(self)`.

method

`ma.MaskedArray.ids()`

Return the addresses of the data and mask areas.

Parameters

None

Examples

```
>>> import numpy as np
>>> x = np.ma.array([1, 2, 3], mask=[0, 1, 1])
>>> x.ids()
(166670640, 166659832) # may vary
```

If the array has no mask, the address of *nomask* is returned. This address is typically not close to the data in memory:

```
>>> x = np.ma.array([1, 2, 3])
>>> x.ids()
(166691080, 3083169284) # may vary
```

method

`ma.MaskedArray.iscontiguous()`

Return a boolean indicating whether the data is contiguous.

Parameters

None

Examples

```
>>> import numpy as np
>>> x = np.ma.array([1, 2, 3])
>>> x.iscontiguous()
True
```

iscontiguous returns one of the flags of the masked array:

```
>>> x.flags
C_CONTIGUOUS : True
F_CONTIGUOUS : True
OWNDATA : False
WRITEABLE : True
ALIGNED : True
WRITEBACKIFCOPY : False
```

Special methods

For standard library functions:

<code>MaskedArray.__copy__()</code>	Used if <code>copy.copy</code> is called on an array.
<code>MaskedArray.__deepcopy__(memo, /)</code>	Used if <code>copy.deepcopy</code> is called on an array.
<code>MaskedArray.__getstate__()</code>	Return the internal state of the masked array, for pickling purposes.
<code>MaskedArray.__reduce__()</code>	Return a 3-tuple for pickling a MaskedArray.
<code>MaskedArray.__setstate__(state)</code>	Restore the internal state of the masked array, for pickling purposes.

method

`ma.MaskedArray.__copy__()`

Used if `copy.copy` is called on an array. Returns a copy of the array.

Equivalent to `a.copy(order='K')`.

method

`ma.MaskedArray.__deepcopy__(memo, /)`

Used if `copy.deepcopy` is called on an array.

method

`ma.MaskedArray.__getstate__()`

Return the internal state of the masked array, for pickling purposes.

method

`ma.MaskedArray.__reduce__()`

Return a 3-tuple for pickling a MaskedArray.

method

`ma.MaskedArray.__setstate__(state)`

Restore the internal state of the masked array, for pickling purposes. `state` is typically the output of the `__getstate__` output, and is a 5-tuple:

- class name
- a tuple giving the shape of the data
- a typecode for the data
- a binary string for the data
- a binary string for the mask.

Basic customization:

<code>MaskedArray.__new__(cls[, data, mask, ...])</code>	Create a new masked array from scratch.
<code>MaskedArray.__array__([dtype], *[, copy])</code>	For <code>dtype</code> parameter it returns a new reference to self if <code>dtype</code> is not given or it matches array's data type.
<code>MaskedArray.__array_wrap__(obj[, context, ...])</code>	Special hook for ufuncs.

method

static `ma.MaskedArray.__new__(cls, data=None, mask=np.False_, dtype=None, copy=False, subok=True, ndmin=0, fill_value=None, keep_mask=True, hard_mask=None, shrink=True, order=None)`

Create a new masked array from scratch.

Notes

A masked array can also be created by taking a `.view(MaskedArray)`.

method

`ma.MaskedArray.__array__([dtype, ], *, copy=None)`

For `dtype` parameter it returns a new reference to self if `dtype` is not given or it matches array's data type. A new array of provided data type is returned if `dtype` is different from the current data type of the array. For `copy` parameter it returns a new reference to self if `copy=False` or `copy=None` and copying isn't enforced by `dtype` parameter. The method returns a new array for `copy=True`, regardless of `dtype` parameter.

A more detailed explanation of the `__array__` interface can be found in `dunder_array.interface`.

method

`ma.MaskedArray.__array_wrap__(obj, context=None, return_scalar=False)`

Special hook for ufuncs.

Wraps the numpy array and sets the mask according to context.

Container customization: (see [Indexing](#))

<code>MaskedArray.__len__()</code>	Return <code>len(self)</code> .
<code>MaskedArray.__getitem__(indx)</code>	<code>x.__getitem__(y) <==> x[y]</code>
<code>MaskedArray.__setitem__(indx, value)</code>	<code>x.__setitem__(i, y) <==> x[i]=y</code>
<code>MaskedArray.__delitem__(key, /)</code>	Delete <code>self[key]</code> .
<code>MaskedArray.__contains__(key, /)</code>	Return <code>bool(key in self)</code> .

method

`ma.MaskedArray.__len__()`

Return `len(self)`.

method

`ma.MaskedArray.__getitem__(indx)`

`x.__getitem__(y) <==> x[y]`

Return the item described by `i`, as a masked array.

method

`ma.MaskedArray.__setitem__(indx, value)`

`x.__setitem__(i, y) <==> x[i]=y`

Set item described by index. If value is masked, masks those locations.

method

`ma.MaskedArray.__delitem__(key, /)`

Delete `self[key]`.

method

`ma.MaskedArray.__contains__(key, /)`

Return `bool(key in self)`.

Specific methods

Handling the mask

The following methods can be used to access information about the mask or to manipulate the mask.

<code>MaskedArray.__setmask__(mask[, copy])</code>	Set the mask.
<code>MaskedArray.harden_mask()</code>	Force the mask to hard, preventing unmasking by assignment.
<code>MaskedArray.soften_mask()</code>	Force the mask to soft (default), allowing unmasking by assignment.
<code>MaskedArray.unshare_mask()</code>	Copy the mask and set the <i>sharedmask</i> flag to <code>False</code> .
<code>MaskedArray.shrink_mask()</code>	Reduce a mask to nomask when possible.

method

`ma.MaskedArray.__setmask__(mask, copy=False)`

Set the mask.

Handling the *fill_value*

<code>MaskedArray.get_fill_value()</code>	The filling value of the masked array is a scalar.
<code>MaskedArray.set_fill_value([value])</code>	

Counting the missing elements

<code>MaskedArray.count([axis, keepdims])</code>	Count the non-masked elements of the array along the given axis.
--	--

1.2.8 The array interface protocol

Note: This page describes the NumPy-specific API for accessing the contents of a NumPy array from other C extensions. [PEP 3118 – The Revised Buffer Protocol](#) introduces similar, standardized API for any extension module to use. Cython’s buffer array support uses the [PEP 3118](#) API; see the [Cython NumPy tutorial](#).

version
3

The array interface (sometimes called array protocol) was created in 2005 as a means for array-like Python objects to reuse each other’s data buffers intelligently whenever possible. The homogeneous N-dimensional array interface is a default mechanism for objects to share N-dimensional array memory and information. The interface consists of a Python-side and a C-side using two attributes. Objects wishing to be considered an N-dimensional array in application code should support at least one of these attributes. Objects wishing to support an N-dimensional array in application code should look for at least one of these attributes and use the information provided appropriately.

This interface describes homogeneous arrays in the sense that each item of the array has the same “type”. This type can be very simple or it can be a quite arbitrary and complicated C-like structure.

There are two ways to use the interface: A Python side and a C-side. Both are separate attributes.

Python side

This approach to the interface consists of the object having an `__array_interface__` attribute.

`object.__array_interface__`

A dictionary of items (3 required and 5 optional). The optional keys in the dictionary have implied defaults if they are not provided.

The keys are:

shape (required)

Tuple whose elements are the array size in each dimension. Each entry is an integer (a Python `int`). Note that these integers could be larger than the platform `int` or `long` could hold (a Python `int` is a C `long`). It is up to the code using this attribute to handle this appropriately; either by raising an error when overflow is possible, or by using `long long` as the C type for the shapes.

typestr (required)

A string providing the basic type of the homogeneous array. The basic string format consists of 3 parts: a character describing the byteorder of the data (<: little-endian, >: big-endian, |: not-relevant), a character code giving the basic type of the array, and an integer providing the number of bytes the type uses.

The basic type character codes are:

t	Bit field (following integer gives the number of bits in the bit field).
b	Boolean (integer type where all values are only <code>True</code> or <code>False</code>)
i	Integer
u	Unsigned integer
f	Floating point
c	Complex floating point
m	Timedelta
M	Datetime
O	Object (i.e. the memory contains a pointer to <code>PyObject</code>)
S	String (fixed-length sequence of char)
U	Unicode (fixed-length sequence of <code>Py_UCS4</code>)
V	Other (void * – each item is a fixed-size chunk of memory)

descr (optional)

A list of tuples providing a more detailed description of the memory layout for each item in the homogeneous array. Each tuple in the list has two or three elements. Normally, this attribute would be used when *typestr* is `V[0-9]+`, but this is not a requirement. The only requirement is that the number of bytes represented in the *typestr* key is the same as the total number of bytes represented here. The idea is to support descriptions of C-like structs that make up array elements. The elements of each tuple in the list are

1. A string providing a name associated with this portion of the datatype. This could also be a tuple of ('full_name', 'basic_name') where basic name would be a valid Python variable name representing the full name of the field.
2. Either a basic-type description string as in *typestr* or another list (for nested structured types)
3. An optional shape tuple providing how many times this part of the structure should be repeated. No repeats are assumed if this is not given. Very complicated structures can be described using this generic interface. Notice, however, that each element of the array is still of the same data-type. Some examples of using this interface are given below.

Default: `[('', typestr)]`

data

A 2-tuple whose first argument is a [Python integer](#) that points to the data-area storing the array contents.

Note: When converting from C/C++ via `PyLong_From*` or high-level bindings such as Cython or `pybind11`, make sure to use an integer of sufficiently large bitness.

This pointer must point to the first element of data (in other words any offset is always ignored in this case). The second entry in the tuple is a read-only flag (`true` means the data area is read-only).

This attribute can also be an object exposing the [buffer interface](#) which will be used to share the data. If this key is `None`, then memory sharing will be done through the buffer interface of the object itself. In this case, the offset key can be used to indicate the start of the buffer. A reference to the object exposing the array interface must be stored by the new object if the memory area is to be secured.

Note: Not specifying this field uses a “scalar” path that we may remove in the future as we are not aware of any users. In this case, NumPy assigns the original object as a scalar into the array.

Changed in version 2.4: Prior to NumPy 2.4 a `NULL` pointer used the undocumented “scalar” path and was thus usually not accepted (and triggered crashes on some paths). After NumPy 2.4, `NULL` is accepted, although NumPy will create a 1-byte sized new allocation for the array.

strides (optional)

Either `None` to indicate a C-style contiguous array or a tuple of strides which provides the number of bytes needed to jump to the next array element in the corresponding dimension. Each entry must be an integer (a Python `int`). As with `shape`, the values may be larger than can be represented by a C `int` or `long`; the calling code should handle this appropriately, either by raising an error, or by using `long long` in C. The default is `None` which implies a C-style contiguous memory buffer. In this model, the last dimension of the array varies the fastest. For example, the default strides tuple for an object whose array entries are 8 bytes long and whose shape is `(10, 20, 30)` would be `(4800, 240, 8)`.

Default: `None` (C-style contiguous)

mask (optional)

`None` or an object exposing the array interface. All elements of the mask array should be interpreted only as true or not true indicating which elements of this array are valid. The shape of this object should be “broadcastable” to the shape of the original array.

Default: `None` (All array values are valid)

offset (optional)

An integer offset into the array data region. This can only be used when data is `None` or returns a `memoryview` object.

Default: `0`.

version (required)

An integer showing the version of the interface (i.e. 3 for this version). Be careful not to use this to invalidate objects exposing future versions of the interface.

C-struct access

This approach to the array interface allows for faster access to an array using only one attribute lookup and a well-defined C-structure.

`object.__array_struct__`

A `PyCapsule` whose `pointer` member contains a pointer to a filled `PyArrayInterface` structure. Memory for the structure is dynamically created and the `PyCapsule` is also created with an appropriate destructor so the retriever of this attribute simply has to apply `Py_DECREF` to the object returned by this attribute when it is finished. Also, either the data needs to be copied out, or a reference to the object exposing this attribute must be held to ensure the data is not freed. Objects exposing the `__array_struct__` interface must also not reallocate their memory if other objects are referencing them.

The `PyArrayInterface` structure is defined in `numpy/ndarrayobject.h` as:

```
typedef struct {
    int two;                /* contains the integer 2 -- simple sanity check */
    int nd;                 /* number of dimensions */
    char typekind;          /* kind in array --- character code of typestr */
    int itemsize;           /* size of each element */
    int flags;              /* flags indicating how the data should be interpreted */
}
```

(continues on next page)

(continued from previous page)

```

/*      must set ARR_HAS_DESCR bit to validate descr */
Py_ssize_t *shape; /* A length-nd array of shape information */
Py_ssize_t *strides; /* A length-nd array of stride information */
void *data; /* A pointer to the first element of the array */
PyObject *descr; /* NULL or data-description (same as descr key
                  of __array_interface__) -- must set ARR_HAS_DESCR
                  flag or this will be ignored. */
} PyArrayInterface;

```

The flags member may consist of 5 bits showing how the data should be interpreted and one bit showing how the Interface should be interpreted. The data-bits are `NPY_ARRAY_C_CONTIGUOUS` (0x1), `NPY_ARRAY_F_CONTIGUOUS` (0x2), `NPY_ARRAY_ALIGNED` (0x100), `NPY_ARRAY_NOTSWAPPED` (0x200), and `NPY_ARRAY_WRITEABLE` (0x400). A final flag `NPY_ARR_HAS_DESCR` (0x800) indicates whether or not this structure has the `arrdescr` field. The field should not be accessed unless this flag is present.

NPY_ARR_HAS_DESCR

New since June 16, 2006:

In the past most implementations used the `desc` member of the `PyCObject` (now `PyCapsule`) itself (do not confuse this with the “`descr`” member of the `PyArrayInterface` structure above — they are two separate things) to hold the pointer to the object exposing the interface. This is now an explicit part of the interface. Be sure to take a reference to the object and call `PyCapsule_SetContext` before returning the `PyCapsule`, and configure a destructor to decref this reference.

Note: `__array_struct__` is considered legacy and should not be used for new code. Use the `buffer protocol` or the `DLPack protocol` `numpy.from_dlpack` instead.

Type description examples

For clarity it is useful to provide some examples of the type description and corresponding `__array_interface__` ‘`descr`’ entries. Thanks to Scott Gilbert for these examples:

In every case, the ‘`descr`’ key is optional, but of course provides more information which may be important for various applications:

```

* Float data
  typestr == '>f4'
  descr == [('', '>f4')]

* Complex double
  typestr == '>c8'
  descr == [ ('real', '>f4'), ('imag', '>f4')]

* RGB Pixel data
  typestr == '|V3'
  descr == [ ('r', '|u1'), ('g', '|u1'), ('b', '|u1')]

* Mixed endian (weird but could happen).
  typestr == '|V8' (or '>u8')
  descr == [ ('big', '>i4'), ('little', '<i4')]

```

(continues on next page)

(continued from previous page)

```

* Nested structure
    struct {
        int ival;
        struct {
            unsigned short sval;
            unsigned char bval;
            unsigned char cval;
        } sub;
    }
    typestr == '|V8' (or '<u8' if you want)
    descr == [ ('ival', '<i4'), ('sub', [ ('sval', '<u2'), ('bval', '|u1'), ('cval', '|u1')
→)) ]

* Nested array
    struct {
        int ival;
        double data[16*4];
    }
    typestr == '|V516'
    descr == [ ('ival', '>i4'), ('data', '>f8', (16, 4)) ]

* Padded structure
    struct {
        int ival;
        double dval;
    }
    typestr == '|V16'
    descr == [ ('ival', '>i4'), ('', '|V4'), ('dval', '>f8') ]

```

It should be clear that any structured type could be described using this interface.

Differences with array interface (version 2)

The version 2 interface was very similar. The differences were largely aesthetic. In particular:

1. The `PyArrayInterface` structure had no `descr` member at the end (and therefore no flag `ARR_HAS_DESCR`)
2. The `context` member of the `PyCapsule` (formally the `desc` member of the `PyCObject`) returned from `__array_struct__` was not specified. Usually, it was the object exposing the array (so that a reference to it could be kept and destroyed when the C-object was destroyed). It is now an explicit requirement that this field be used in some way to hold a reference to the owning object.

Note: Until August 2020, this said:

Now it must be a tuple whose first element is a string with “PyArrayInterface Version #” and whose second element is the object exposing the array.

This design was retracted almost immediately after it was proposed, in <https://mail.python.org/pipermail/numpy-discussion/2006-June/020995.html>. Despite 14 years of documentation to the contrary, at no point was it valid to assume that `__array_interface__` capsules held this tuple content.

3. The tuple returned from `__array_interface__['data']` used to be a hex-string (now it is an integer or a long integer).
4. There was no `__array_interface__` attribute instead all of the keys (except for version) in the `__array_interface__` dictionary were their own attribute: Thus to obtain the Python-side information you had to

access separately the attributes:

- `__array_data__`
- `__array_shape__`
- `__array_strides__`
- `__array_typedstr__`
- `__array_descr__`
- `__array_offset__`
- `__array_mask__`

1.2.9 Datetimes and timedeltas

Starting in NumPy 1.7, there are core array data types which natively support datetime functionality. The data type is called `datetime64`, so named because `datetime` is already taken by the Python standard library.

Datetime64 conventions and assumptions

Similar to the Python `date` class, dates are expressed in the current Gregorian Calendar, indefinitely extended both in the future and in the past.¹ Contrary to Python `date`, which supports only years in the 1 AD — 9999 AD range, `datetime64` allows also for dates BC; years BC follow the [Astronomical year numbering](#) convention, i.e. year 2 BC is numbered `-1`, year 1 BC is numbered `0`, year 1 AD is numbered `1`.

Time instants, say `16:23:32.234`, are represented counting hours, minutes, seconds and fractions from midnight: i.e. `00:00:00.000` is midnight, `12:00:00.000` is noon, etc. Each calendar day has exactly 86400 seconds. This is a “naive” time, with no explicit notion of timezones or specific time scales (UT1, UTC, TAI, etc.).²

Basic datetimes

The most basic way to create datetimes is from strings in ISO 8601 date or datetime format. It is also possible to create datetimes from an integer by offset relative to the Unix epoch (`00:00:00 UTC` on 1 January 1970). The unit for internal storage is automatically selected from the form of the string, and can be either a *date unit* or a *time unit*. The date units are years (`'Y'`), months (`'M'`), weeks (`'W'`), and days (`'D'`), while the time units are hours (`'h'`), minutes (`'m'`), seconds (`'s'`), milliseconds (`'ms'`), and some additional SI-prefix seconds-based units. The `datetime64` data type also accepts the string `“NAT”`, in any combination of lowercase/uppercase letters, for a “Not A Time” value. The string `“now”` is also supported and returns the current UTC time. By default, it uses second (`'s'`) precision, but you can specify a different unit (e.g., `'M'`, `'D'`, `'h'`) to truncate the result to that precision. Units finer than seconds (such as `'ms'` or `'ns'`) are supported but will show fractional parts as zeros, effectively truncating to whole seconds. The string `“today”` is also supported and returns the current UTC date with day precision. It also supports the same precision specifiers as `now`.

Example

A simple ISO date:

```
>>> import numpy as np
```

¹ The calendar obtained by extending the Gregorian calendar before its official adoption on Oct. 15, 1582 is called [Proleptic Gregorian Calendar](#)

² The assumption of 86400 seconds per calendar day is not valid for UTC, the present day civil time scale. In fact due to the presence of [leap seconds](#) on rare occasions a day may be 86401 or 86399 seconds long. On the contrary the 86400s day assumption holds for the TAI timescale. An explicit support for TAI and TAI to UTC conversion, accounting for leap seconds, is proposed but not yet implemented. See also the [shortcomings](#) section below.

```
>>> np.datetime64('2005-02-25')
np.datetime64('2005-02-25')
```

From an integer and a date unit, 1 year since the UNIX epoch:

```
>>> np.datetime64(1, 'Y')
np.datetime64('1971')
```

Using months for the unit:

```
>>> np.datetime64('2005-02')
np.datetime64('2005-02')
```

Specifying just the month, but forcing a ‘days’ unit:

```
>>> np.datetime64('2005-02', 'D')
np.datetime64('2005-02-01')
```

From a date and time:

```
>>> np.datetime64('2005-02-25T03:30')
np.datetime64('2005-02-25T03:30')
```

NAT (not a time):

```
>>> np.datetime64('nat', 'D')
np.datetime64('NaT', 'D')
```

The current time (UTC, default second precision):

```
>>> np.datetime64('now')
np.datetime64('2025-08-05T02:22:14') # result will depend on the current time
```

```
>>> np.datetime64('now', 'D')
np.datetime64('2025-08-05')
```

```
>>> np.datetime64('now', 'ms')
np.datetime64('2025-08-05T02:22:14.000')
```

The current date:

```
>>> np.datetime64('today')
np.datetime64('2025-08-05') # result will depend on the current date
```

When creating an array of datetimes from a string, it is still possible to automatically select the unit from the inputs, by using the datetime type with generic units.

Deprecated since version 2.5: The generic units of `timedelta64` were deprecated in NumPy 2.5 and will raise an error in the future. With this change, NaT in `datetime64` is now required to have an explicit time unit.

Example

```
>>> import numpy as np
```

```
>>> np.array(['2007-07-13', '2006-01-13', '2010-08-13'], dtype=np.datetime64)
array(['2007-07-13', '2006-01-13', '2010-08-13'], dtype='datetime64[D]')
```

```
>>> np.array(['2001-01-01T12:00', '2002-02-03T13:56:03.172'], dtype=np.datetime64)
array(['2001-01-01T12:00:00.000', '2002-02-03T13:56:03.172'],
      dtype='datetime64[ms]')
```

An array of datetimes can be constructed from integers representing POSIX timestamps with the given unit.

Example

```
>>> import numpy as np
```

```
>>> np.array([0, 1577836800], dtype='datetime64[s]')
array(['1970-01-01T00:00:00', '2020-01-01T00:00:00'],
      dtype='datetime64[s]')
```

```
>>> np.array([0, 1577836800000]).astype('datetime64[ms]')
array(['1970-01-01T00:00:00.000', '2020-01-01T00:00:00.000'],
      dtype='datetime64[ms]')
```

The datetime type works with many common NumPy functions, for example *arange* can be used to generate ranges of dates.

Example

All the dates for one month:

```
>>> import numpy as np
```

```
>>> np.arange('2005-02', '2005-03', dtype='datetime64[D]')
array(['2005-02-01', '2005-02-02', '2005-02-03', '2005-02-04',
      '2005-02-05', '2005-02-06', '2005-02-07', '2005-02-08',
      '2005-02-09', '2005-02-10', '2005-02-11', '2005-02-12',
      '2005-02-13', '2005-02-14', '2005-02-15', '2005-02-16',
      '2005-02-17', '2005-02-18', '2005-02-19', '2005-02-20',
      '2005-02-21', '2005-02-22', '2005-02-23', '2005-02-24',
      '2005-02-25', '2005-02-26', '2005-02-27', '2005-02-28'],
      dtype='datetime64[D]')
```

The datetime object represents a single moment in time. If two datetimes have different units, they may still be representing the same moment of time, and converting from a bigger unit like months to a smaller unit like days is considered a ‘safe’ cast because the moment of time is still being represented exactly.

Example

```
>>> import numpy as np
```

```
>>> np.datetime64('2005') == np.datetime64('2005-01-01')
True
```

```
>>> np.datetime64('2010-03-14T15') == np.datetime64('2010-03-14T15:00:00.00')
True
```

Deprecated since version 1.11.0: NumPy does not store timezone information. For backwards compatibility, `datetime64` still parses timezone offsets, which it handles by converting to UTC±00:00 (Zulu time). This behaviour is deprecated and will raise an error in the future.

Datetime and timedelta arithmetic

NumPy allows the subtraction of two datetime values, an operation which produces a number with a time unit. Because NumPy doesn't have a physical quantities system in its core, the `timedelta64` data type was created to complement `datetime64`. The arguments for `timedelta64` are a number, to represent the number of units, and a date/time unit, such as (D)ay, (M)onth, (Y)ear, (h)ours, (m)inutes, or (s)econds. The `timedelta64` data type also accepts the string "NAT" in place of the number for a "Not A Time" value.

Example

```
>>> import numpy as np
```

```
>>> np.timedelta64(1, 'D')
np.timedelta64(1, 'D')
```

```
>>> np.timedelta64(4, 'h')
np.timedelta64(4, 'h')
```

```
>>> np.timedelta64('NaT', 'D')
np.timedelta64('NaT', 'D')
```

Datetimes and Timedeltas work together to provide ways for simple datetime calculations.

Example

```
>>> import numpy as np
```

```
>>> np.datetime64('2009-01-01') - np.datetime64('2008-01-01')
np.timedelta64(366, 'D')
```

```
>>> np.datetime64('2009') + np.timedelta64(20, 'D')
np.datetime64('2009-01-21')
```

```
>>> np.datetime64('2011-06-15T00:00') + np.timedelta64(12, 'h')
np.datetime64('2011-06-15T12:00')
```

```
>>> np.timedelta64(1, 'W') / np.timedelta64(1, 'D')
7.0
```

```
>>> np.timedelta64(1, 'W') % np.timedelta64(10, 'D')
np.timedelta64(7, 'D')
```

```
>>> np.datetime64('nat', 'D') - np.datetime64('2009-01-01')
np.timedelta64('NaT', 'D')
```

```
>>> np.datetime64('2009-01-01') + np.timedelta64('nat', 'D')
np.datetime64('NaT', 'D')
```

There are two Timedelta units ('Y', years and 'M', months) which are treated specially, because how much time they represent changes depending on when they are used. While a timedelta day unit is equivalent to 24 hours, month and year units cannot be converted directly into days without using 'unsafe' casting.

The `numpy.ndarray.astype` method can be used for unsafe conversion of months/years to days. The conversion follows calculating the averaged values from the 400 year leap-year cycle.

Example

```
>>> import numpy as np
```

```
>>> a = np.timedelta64(1, 'Y')
```

```
>>> np.timedelta64(a, 'M')
numpy.timedelta64(12, 'M')
```

```
>>> np.timedelta64(a, 'D')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: Cannot cast NumPy timedelta64 scalar from metadata [Y] to [D] according to
↳the rule 'same_kind'
```

Datetime units

The Datetime and Timedelta data types support a large number of time units, as well as generic units which can be coerced into any of the other units based on input data. The generic units are deprecated since NumPy 2.5 and will raise an error in the future. Migration guidance is provided in the [migration guide for deprecation of generic units](#) section below.

Datetimes are always stored with an epoch of 1970-01-01T00:00. This means the supported dates are always a symmetric interval around the epoch, called “time span” in the table below.

The length of the span is the range of a 64-bit integer times the length of the date or unit. For example, the time span for 'W' (week) is exactly 7 times longer than the time span for 'D' (day), and the time span for 'D' (day) is exactly 24 times longer than the time span for 'h' (hour).

Here are the date units:

Code	Meaning	Time span (relative)	Time span (absolute)
Y	year	+/- 9.2e18 years	[9.2e18 BC, 9.2e18 AD]
M	month	+/- 7.6e17 years	[7.6e17 BC, 7.6e17 AD]
W	week	+/- 1.7e17 years	[1.7e17 BC, 1.7e17 AD]
D	day	+/- 2.5e16 years	[2.5e16 BC, 2.5e16 AD]

And here are the time units:

Code	Meaning	Time span (relative)	Time span (absolute)
h	hour	+/- 1.0e15 years	[1.0e15 BC, 1.0e15 AD]
m	minute	+/- 1.7e13 years	[1.7e13 BC, 1.7e13 AD]
s	second	+/- 2.9e11 years	[2.9e11 BC, 2.9e11 AD]
ms	millisecond	+/- 2.9e8 years	[2.9e8 BC, 2.9e8 AD]
us / μ s	microsecond	+/- 2.9e5 years	[290301 BC, 294241 AD]
ns	nanosecond	+/- 292 years	[1678 AD, 2262 AD]
ps	picosecond	+/- 106 days	[1969 AD, 1970 AD]
fs	femtosecond	+/- 2.6 hours	[1969 AD, 1970 AD]
as	attosecond	+/- 9.2 seconds	[1969 AD, 1970 AD]

Converting datetime and timedelta to Python Object

NumPy follows a strict protocol when converting *datetime64* and/or *timedelta64* to Python Objects (e.g., tuple, list, *datetime.datetime*).

The protocol is described in the following table:

Input Type	for <i>datetime64</i>	for <i>timedelta64</i>
NaT	None	None
ns/ps/fs/as	int	int
μ s/ms/s/m/h	<i>datetime.datetime</i>	<i>datetime.timedelta</i>
D/W (Linear units)	<i>datetime.date</i>	<i>datetime.timedelta</i>
Y/M (Non-linear units)	<i>datetime.date</i>	int
Generic units	<i>datetime.date</i>	int

Deprecated since version 2.5: The generic units of *timedelta64* are deprecated in NumPy 2.5 and will raise an error in the future.

Example

```
>>> import numpy as np
```

```
>>> type(np.datetime64('NaT', 'D').item())
<class 'NoneType'>
```

```
>>> type(np.timedelta64('NaT', 'D').item())
<class 'NoneType'>
```

```
>>> type(np.timedelta64(123, 'ns').item())
<class 'int'>
```

```
>>> type(np.datetime64('2025-01-01T12:00:00.123456').item())
<class 'datetime.datetime'>
```

```
>>> type(np.timedelta64(10, 'D').item())
<class 'datetime.timedelta'>
```

In the case where conversion of *datetime64* and/or *timedelta64* is done against Python types like `int`, `float`, and `str` the corresponding return types will be `np.str_`, `np.int64` and `np.float64`.

Example

```
>>> import numpy as np
```

```
>>> type(np.timedelta64(1, 'D').astype(int))
<class 'numpy.int64'>
```

```
>>> type(np.datetime64('2025-01-01T12:00:00.123456').astype(float))
<class 'numpy.float64'>
```

```
>>> type(np.timedelta64(123, 'ns').astype(str))
<class 'numpy.str_'>
```

Business day functionality

To allow the datetime to be used in contexts where only certain days of the week are valid, NumPy includes a set of “busday” (business day) functions.

The default for busday functions is that the only valid days are Monday through Friday (the usual business days). The implementation is based on a “weekmask” containing 7 Boolean flags to indicate valid days; custom weekmasks are possible that specify other sets of valid days.

The “busday” functions can additionally check a list of “holiday” dates, specific dates that are not valid days.

The function *busday_offset* allows you to apply offsets specified in business days to datetimes with a unit of ‘D’ (day).

Example

```
>>> import numpy as np
```

```
>>> np.busday_offset('2011-06-23', 1)
np.datetime64('2011-06-24')
```

```
>>> np.busday_offset('2011-06-23', 2)
np.datetime64('2011-06-27')
```

When an input date falls on the weekend or a holiday, *busday_offset* first applies a rule to roll the date to a valid business day, then applies the offset. The default rule is ‘raise’, which simply raises an exception. The rules most typically used are ‘forward’ and ‘backward’.

Example

```
>>> import numpy as np
```

```
>>> np.busday_offset('2011-06-25', 2)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Non-business day date in busday_offset
```

```
>>> np.busday_offset('2011-06-25', 0, roll='forward')
np.datetime64('2011-06-27')
```

```
>>> np.busday_offset('2011-06-25', 2, roll='forward')
np.datetime64('2011-06-29')
```

```
>>> np.busday_offset('2011-06-25', 0, roll='backward')
np.datetime64('2011-06-24')
```

```
>>> np.busday_offset('2011-06-25', 2, roll='backward')
np.datetime64('2011-06-28')
```

In some cases, an appropriate use of the roll and the offset is necessary to get a desired answer.

Example

The first business day on or after a date:

```
>>> import numpy as np
```

```
>>> np.busday_offset('2011-03-20', 0, roll='forward')
np.datetime64('2011-03-21')
>>> np.busday_offset('2011-03-22', 0, roll='forward')
np.datetime64('2011-03-22')
```

The first business day strictly after a date:

```
>>> np.busday_offset('2011-03-20', 1, roll='backward')
np.datetime64('2011-03-21')
>>> np.busday_offset('2011-03-22', 1, roll='backward')
np.datetime64('2011-03-23')
```

The function is also useful for computing some kinds of days like holidays. In Canada and the U.S., Mother's day is on the second Sunday in May, which can be computed with a custom weekmask.

Example

```
>>> import numpy as np
```

```
>>> np.busday_offset('2012-05', 1, roll='forward', weekmask='Sun')
np.datetime64('2012-05-13')
```

When performance is important for manipulating many business dates with one particular choice of weekmask and holidays, there is an object *busdaycalendar* which stores the data necessary in an optimized form.

np.is_busday():

To test a *datetime64* value to see if it is a valid day, use *is_busday*.

Example

```
>>> import numpy as np
```

```
>>> np.is_busday(np.datetime64('2011-07-15')) # a Friday
True
>>> np.is_busday(np.datetime64('2011-07-16')) # a Saturday
False
>>> np.is_busday(np.datetime64('2011-07-16'), weekmask="Sat Sun")
True
>>> a = np.arange(np.datetime64('2011-07-11'), np.datetime64('2011-07-18'))
>>> np.is_busday(a)
array([ True,  True,  True,  True,  True, False, False])
```

np.busday_count():

To find how many valid days there are in a specified range of *datetime64* dates, use *busday_count*:

Example

```
>>> import numpy as np
```

```
>>> np.busday_count(np.datetime64('2011-07-11'), np.datetime64('2011-07-18'))
5
>>> np.busday_count(np.datetime64('2011-07-18'), np.datetime64('2011-07-11'))
-5
```

If you have an array of *datetime64* day values, and you want a count of how many of them are valid dates, you can do this:

Example

```
>>> import numpy as np
```

```
>>> a = np.arange(np.datetime64('2011-07-11'), np.datetime64('2011-07-18'))
>>> np.count_nonzero(np.is_busday(a))
5
```

Custom weekmasks

Here are several examples of custom weekmask values. These examples specify the “busday” default of Monday through Friday being valid days.

Some examples:

```
# Positional sequences; positions are Monday through Sunday.
# Length of the sequence must be exactly 7.
weekmask = [1, 1, 1, 1, 1, 0, 0]
# list or other sequence; 0 == invalid day, 1 == valid day
weekmask = "1111100"
# string '0' == invalid day, '1' == valid day

# string abbreviations from this list: Mon Tue Wed Thu Fri Sat Sun
weekmask = "Mon Tue Wed Thu Fri"
# any amount of whitespace is allowed; abbreviations are case-sensitive.
weekmask = "MonTue Wed Thu\tFri"
```

Datetime64 shortcomings

The assumption that all days are exactly 86400 seconds long makes `datetime64` largely compatible with Python `datetime` and “POSIX time” semantics; therefore they all share the same well known shortcomings with respect to the UTC timescale and historical time determination. A brief non exhaustive summary is given below.

- It is impossible to parse valid UTC timestamps occurring during a positive leap second.

Example

“2016-12-31 23:59:60 UTC” was a leap second, therefore “2016-12-31 23:59:60.450 UTC” is a valid timestamp which is not parseable by `datetime64`:

```
>>> import numpy as np
```

```
>>> np.datetime64("2016-12-31 23:59:60.450")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Seconds out of range in datetime string "2016-12-31 23:59:60.450"
```

-
- `Timedelta64` computations between two UTC dates can be wrong by an integer number of SI seconds.

Example

Compute the number of SI seconds between “2021-01-01 12:56:23.423 UTC” and “2001-01-01 00:00:00.000 UTC”:

```
>>> import numpy as np
```

```
>>> (
...     np.datetime64("2021-01-01 12:56:23.423")
...     - np.datetime64("2001-01-01")
... ) / np.timedelta64(1, "s")
631198583.423
```

However, the correct answer is *631198588.423* SI seconds, because there were 5 leap seconds between 2001 and 2021.

- `Timedelta64` computations for dates in the past do not return SI seconds, as one would expect.

Example

Compute the number of seconds between “000-01-01 UT” and “1600-01-01 UT”, where UT is [universal time](#):

```
>>> import numpy as np
```

```
>>> a = np.datetime64("0000-01-01", "us")
>>> b = np.datetime64("1600-01-01", "us")
>>> b - a
numpy.timedelta64(504911232000000000, 'us')
```

The computed results, *50491123200* seconds, are obtained as the elapsed number of days (*584388*) times *86400* seconds; this is the number of seconds of a clock in sync with the Earth’s rotation. The exact value in SI seconds can only be estimated, e.g., using data published in [Measurement of the Earth’s rotation: 720 BC to AD 2015, 2016, Royal Society’s Proceedings A 472](#), by Stephenson et.al.. A sensible estimate is *50491112870 ± 90* seconds, with a difference of 10330 seconds.

Migration guide for deprecation of generic units

The generic units of `timedelta64` are deprecated since NumPy 2.5 and will raise an error in the future. This section provides guidance on how to update code that uses generic units of `timedelta64` and `datetime64` to avoid future errors.

The straight forward way is to replace the generic unit with a specific time unit such as ‘D’ (day), ‘h’ (hour), ‘m’ (minute), ‘s’ (second), etc. The choice of the specific time unit will depend on the context of your code and the level of precision you require.

Example

```
>>> import numpy as np
```

```
>>> # Old code using generic units of timedelta64
>>> np.timedelta64(5, "s") + 1
DeprecationWarning: The 'generic' unit for NumPy timedelta is deprecated, and will
↳ raise an error in the future. This includes implicit conversion of bare integers (e.
↳ g. `+ 1`). Please use a specific unit instead.
```

```
>>> # Updated code using a specific time unit
>>> np.timedelta64(5, "s") + np.timedelta64(1, "s")
np.timedelta64(6, 's')
```

When comparing `timedelta64` objects, make sure to use the same specific time unit for both operands even if they are representing 0.

```
>>> np.timedelta64(0, "s") == 0
DeprecationWarning: The 'generic' unit for NumPy timedelta is deprecated, and will
```

(continues on next page)

(continued from previous page)

```
↳ raise an error in the future. This includes implicit conversion of bare integers (e.
↳ g. `== 0`). Please use a specific unit instead.
np.True_
```

```
>>> np.timedelta64(0, "s") == np.timedelta64(0, "s")
np.True_
```

When using `numpy.testing.assert_allclose` to compare `timedelta64` objects, ensure to set a specific time unit to `atol` parameter as well.

```
>>> arr = np.ones(5, dtype='m8[s]')
>>> np.testing.assert_allclose(arr, np.timedelta64(1, "s"), atol=np.timedelta64(0, "s"
↳ ))
```

Previously, `datetime64` allowed `NaT` without specifying a time unit. With the deprecation of generic units, `NaT` is now required to have an explicit time unit for consistency with other datetime and timedelta operations.

```
>>> np.datetime64("NaT")
DeprecationWarning: The 'generic' unit for NumPy timedelta is deprecated, and will
↳ raise an error in the future. This includes implicit conversion of bare integers (e.
↳ g. `+ 1`). Please use a specific unit instead.
```

```
>>> np.datetime64("NaT", "D")
np.datetime64('NaT', 'D')
```

1.3 Universal functions (ufunc)

See also:

`ufuncs-basics`

A universal function (or ufunc for short) is a function that operates on `ndarrays` in an element-by-element fashion, supporting array broadcasting, type casting, and several other standard features. That is, a ufunc is a “vectorized” wrapper for a function that takes a fixed number of specific inputs and produces a fixed number of specific outputs. For detailed information on universal functions, see `ufuncs-basics`.

There are also *generalized ufuncs* which are functions over vectors (or arrays) instead of only single-element scalars.

1.3.1 ufunc

`numpy.ufunc()`

Functions that operate element by element on whole arrays.

class `numpy.ufunc`

Functions that operate element by element on whole arrays.

To see the documentation for a specific ufunc, use `info`. For example, `np.info(np.sin)`. Because ufuncs are written in C (for speed) and linked into Python with NumPy’s ufunc facility, Python’s `help()` function finds this page whenever `help()` is called on a ufunc.

A detailed explanation of ufuncs can be found in the docs for *Universal functions (ufunc)*.

Calling ufuncs: `op(*x[, out], where=True, **kwargs)`

Apply *op* to the arguments **x* elementwise, broadcasting the arguments.

The broadcasting rules are:

- Dimensions of length 1 may be prepended to either array.
- Arrays may be repeated along dimensions of length 1.

Parameters

***x**

[array_like] Input arrays.

out

[ndarray, None, ..., or tuple of ndarray and None, optional] Location(s) into which the result(s) are stored. If not provided or None, new array(s) are created by the ufunc. If passed as a keyword argument, can be Ellipses (`out=...`) to ensure an array is returned even if the result is 0-dimensional, or a tuple with length equal to the number of outputs (where None can be used for allocation by the ufunc).

New in version 2.3: Support for `out=...` was added.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Attributes

identity

The identity value.

nargs

The number of arguments.

nin

The number of inputs.

nout

The number of outputs.

ntypes

The number of types.

signature

Definition of the core elements a generalized ufunc operates on.

types

Returns a list with types grouped input->output.

Methods

<code>__call__(*args, **kwargs)</code>	Call self as a function.
<code>accumulate(array[, axis, dtype, out])</code>	Accumulate the result of applying the operator to all elements.
<code>at(a, indices[, b])</code>	Performs unbuffered in place operation on operand 'a' for elements specified by 'indices'.
<code>outer(A, B, /, **kwargs)</code>	Apply the ufunc <i>op</i> to all pairs (a, b) with a in A and b in B.
<code>reduce(array[, axis, dtype, out, keepdims, ...])</code>	Reduces <code>array</code> 's dimension by one, by applying ufunc along one axis.
<code>reduceat(array, indices[, axis, dtype, out])</code>	Performs a (local) reduce with specified slices over a single axis.
<code>resolve_dtypes(dtypes, *[, signature, ...])</code>	Find the dtypes NumPy will use for the operation.

method

ufunc.**__call__** (*args, **kwargs)

Call self as a function.

method

ufunc.**accumulate** (array, axis=0, dtype=None, out=None)

Accumulate the result of applying the operator to all elements.

For a one-dimensional array, accumulate produces results equivalent to:

```
r = np.empty(len(A))
t = op.identity      # op = the ufunc being applied to A's elements
for i in range(len(A)):
    t = op(t, A[i])
    r[i] = t
return r
```

For example, `add.accumulate()` is equivalent to `np.cumsum()`.

For a multi-dimensional array, `accumulate` is applied along only one axis (axis zero by default; see Examples below) so repeated use is necessary if one wants to accumulate over multiple axes.

Parameters

array

[array_like] The array to act on.

axis

[int, optional] The axis along which to apply the accumulation; default is zero.

dtype

[data-type code, optional] The data-type used to represent the intermediate results. Defaults to the data-type of the output array if such is provided, or the data-type of the input array if no output array is provided.

out

[ndarray, None, or tuple of ndarray and None, optional] Location into which the result is stored. If not provided or None, a freshly-allocated array is returned. For consistency with `ufunc.__call__`, if passed as a keyword argument, can be Ellipses (`out=...`, which has the same effect as None as an array is always returned), or a 1-element tuple.

Returns

r
 [ndarray] The accumulated values. If *out* was supplied, *r* is a reference to *out*.

Examples

1-D array examples:

```
>>> import numpy as np
>>> np.add.accumulate([2, 3, 5])
array([ 2,  5, 10])
>>> np.multiply.accumulate([2, 3, 5])
array([ 2,  6, 30])
```

2-D array examples:

```
>>> I = np.eye(2)
>>> I
array([[1.,  0.],
       [0.,  1.]])
```

Accumulate along axis 0 (rows), down columns:

```
>>> np.add.accumulate(I, 0)
array([[1.,  0.],
       [1.,  1.]])
>>> np.add.accumulate(I) # no axis specified = axis zero
array([[1.,  0.],
       [1.,  1.]])
```

Accumulate along axis 1 (columns), through rows:

```
>>> np.add.accumulate(I, 1)
array([[1.,  1.],
       [0.,  1.]])
```

method

`ufunc.at(a, indices, b=None, /)`

Performs unbuffered in place operation on operand ‘a’ for elements specified by ‘indices’. For addition `ufunc`, this method is equivalent to `a[indices] += b`, except that results are accumulated for elements that are indexed more than once. For example, `a[[0, 0]] += 1` will only increment the first element once because of buffering, whereas `add.at(a, [0, 0], 1)` will increment the first element twice.

Parameters

a
 [array_like] The array to perform in place operation on.

indices
 [array_like or tuple] Array like index object or slice object for indexing into first operand. If first operand has multiple dimensions, indices can be a tuple of array like index objects or slice objects.

b
 [array_like] Second operand for ufuncs requiring two operands. Operand must be broadcastable over first operand after indexing or slicing.

Examples

Set items 0 and 1 to their negative values:

```
>>> import numpy as np
>>> a = np.array([1, 2, 3, 4])
>>> np.negative.at(a, [0, 1])
>>> a
array([-1, -2,  3,  4])
```

Increment items 0 and 1, and increment item 2 twice:

```
>>> a = np.array([1, 2, 3, 4])
>>> np.add.at(a, [0, 1, 2, 2], 1)
>>> a
array([2, 3, 5, 4])
```

Add items 0 and 1 in first array to second array, and store results in first array:

```
>>> a = np.array([1, 2, 3, 4])
>>> b = np.array([1, 2])
>>> np.add.at(a, [0, 1], b)
>>> a
array([2, 4, 3, 4])
```

method

`ufunc.outter(A, B, /, **kwargs)`

Apply the ufunc *op* to all pairs (a, b) with a in *A* and b in *B*.

Let $M = A.\text{ndim}$, $N = B.\text{ndim}$. Then the result, *C*, of `op.outter(A, B)` is an array of dimension $M + N$ such that:

$$C[i_0, \dots, i_{M-1}, j_0, \dots, j_{N-1}] = op(A[i_0, \dots, i_{M-1}], B[j_0, \dots, j_{N-1}])$$

For *A* and *B* one-dimensional, this is equivalent to:

```
r = empty(len(A), len(B))
for i in range(len(A)):
    for j in range(len(B)):
        r[i, j] = op(A[i], B[j]) # op = ufunc in question
```

Parameters

A

[array_like] First array

B

[array_like] Second array

kwargs

[any] Arguments to pass on to the ufunc. Typically *dtype* or *out*. See *ufunc* for a comprehensive overview of all available arguments.

Returns

r

[ndarray] Output array

See also:

`numpy.outer`

A less powerful version of `np.multiply.outer` that *ravels* all inputs to 1D. This exists primarily for compatibility with old code.

`tensordot`

`np.tensordot(a, b, axes=(), ())` and `np.multiply.outer(a, b)` behave same for all dimensions of `a` and `b`.

Examples

```
>>> np.multiply.outer([1, 2, 3], [4, 5, 6])
array([[ 4,  5,  6],
       [ 8, 10, 12],
       [12, 15, 18]])
```

A multi-dimensional example:

```
>>> A = np.array([[1, 2, 3], [4, 5, 6]])
>>> A.shape
(2, 3)
>>> B = np.array([[1, 2, 3, 4]])
>>> B.shape
(1, 4)
>>> C = np.multiply.outer(A, B)
>>> C.shape; C
(2, 3, 1, 4)
array([[[[ 1,  2,  3,  4]],
        [[ 2,  4,  6,  8]],
        [[ 3,  6,  9, 12]]],
       [[[ 4,  8, 12, 16]],
        [[ 5, 10, 15, 20]],
        [[ 6, 12, 18, 24]]]])
```

method

`ufunc.reduce(array, axis=0, dtype=None, out=None, keepdims=False, initial=<no value>, where=True)`

Reduces `array`'s dimension by one, by applying `ufunc` along one axis.

Let `array.shape = (N0, ..., Ni, ..., NM-1)`. Then `ufunc.reduce(array, axis = i)[k0, ..., ki-1, ki+1, ..., kM-1]` = the result of iterating `j` over `range(Ni)`, cumulatively applying `ufunc` to each `array[k0, ..., ki-1, j, ki+1, ..., kM-1]`. For a one-dimensional array, `reduce` produces results equivalent to:

```
r = op.identity # op = ufunc
for i in range(len(A)):
    r = op(r, A[i])
return r
```

For example, `add.reduce()` is equivalent to `sum()`.

Parameters

`array`

[array_like] The array to act on.

axis

[None or int or tuple of ints, optional] Axis or axes along which a reduction is performed. The default (*axis* = 0) is perform a reduction over the first dimension of the input array. *axis* may be negative, in which case it counts from the last to the first axis.

If this is None, a reduction is performed over all the axes. If this is a tuple of ints, a reduction is performed on multiple axes, instead of a single axis or all the axes as before.

For operations which are either not commutative or not associative, doing a reduction over multiple axes is not well-defined. The ufuncs do not currently raise an exception in this case, but will likely do so in the future.

dtype

[data-type code, optional] The data type used to perform the operation. Defaults to that of *out* if given, and the data type of *array* otherwise (though upcast to conserve precision for some cases, such as `numpy.add.reduce` for integer or boolean input).

out

[ndarray, None, ..., or tuple of ndarray and None, optional] Location into which the result is stored. If not provided or None, a freshly-allocated array is returned. If passed as a keyword argument, can be Ellipses (*out*=...) to ensure an array is returned even if the result is 0-dimensional (which is useful especially for object dtype), or a 1-element tuple (latter for consistency with `ufunc.__call__`).

New in version 2.3: Support for *out*=... was added.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *array*.

initial

[scalar, optional] The value with which to start the reduction. If the ufunc has no identity or the dtype is object, this defaults to None - otherwise it defaults to `ufunc.identity`. If None is given, the first element of the reduction is used, and an error is thrown if the reduction is empty.

where

[array_like of bool, optional] A boolean array which is broadcasted to match the dimensions of *array*, and selects elements to include in the reduction. Note that for ufuncs like `minimum` that do not have an identity defined, one has to pass in also *initial*.

Returns**r**

[ndarray] The reduced array. If *out* was supplied, *r* is a reference to it.

Examples

```
>>> import numpy as np
>>> np.multiply.reduce([2,3,5])
30
```

A multi-dimensional array example:

```
>>> X = np.arange(8).reshape((2,2,2))
>>> X
array([[[0, 1],
```

(continues on next page)

(continued from previous page)

```

        [2, 3]],
        [[4, 5],
        [6, 7]])
>>> np.add.reduce(X, 0)
array([[ 4,  6],
       [ 8, 10]])
>>> np.add.reduce(X) # confirm: default axis value is 0
array([[ 4,  6],
       [ 8, 10]])
>>> np.add.reduce(X, 1)
array([[ 2,  4],
       [10, 12]])
>>> np.add.reduce(X, 2)
array([[ 1,  5],
       [ 9, 13]])

```

You can use the `initial` keyword argument to initialize the reduction with a different value, and `where` to select specific elements to include:

```

>>> np.add.reduce([10], initial=5)
15
>>> np.add.reduce(np.ones((2, 2, 2)), axis=(0, 2), initial=10)
array([14., 14.])
>>> a = np.array([10., np.nan, 10])
>>> np.add.reduce(a, where=~np.isnan(a))
20.0

```

Allows reductions of empty arrays where they would normally fail, i.e. for ufuncs without an identity.

```

>>> np.minimum.reduce([], initial=np.inf)
inf
>>> np.minimum.reduce([[1., 2.], [3., 4.]], initial=10., where=[True, False])
array([ 1., 10.])
>>> np.minimum.reduce([])
Traceback (most recent call last):
...
ValueError: zero-size array to reduction operation minimum which has no
↪identity

```

method

ufunc.**reduceat** (*array, indices, axis=0, dtype=None, out=None*)

Performs a (local) reduce with specified slices over a single axis.

For `i` in `range(len(indices))`, `reduceat` computes `ufunc.reduce(array[indices[i]:indices[i+1]])`, which becomes the `i`-th generalized “row” parallel to `axis` in the final result (i.e., in a 2-D array, for example, if `axis = 0`, it becomes the `i`-th row, but if `axis = 1`, it becomes the `i`-th column). There are three exceptions to this:

- when `i = len(indices) - 1` (so for the last index), `indices[i+1] = array.shape[axis]`.
- if `indices[i] >= indices[i + 1]`, the `i`-th generalized “row” is simply `array[indices[i]]`.
- if `indices[i] >= len(array)` or `indices[i] < 0`, an error is raised.

The shape of the output depends on the size of `indices`, and may be larger than `array` (this happens if `len(indices) > array.shape[axis]`).

Parameters**array**

[array_like] The array to act on.

indices

[array_like] Paired indices, comma separated (not colon), specifying slices to reduce.

axis

[int, optional] The axis along which to apply the reduceat.

dtype

[data-type code, optional] The data type used to perform the operation. Defaults to that of `out` if given, and the data type of `array` otherwise (though upcast to conserve precision for some cases, such as `numpy.add.reduce` for integer or boolean input).

out

[ndarray, None, or tuple of ndarray and None, optional] Location into which the result is stored. If not provided or None, a freshly-allocated array is returned. For consistency with `ufunc.__call__`, if passed as a keyword argument, can be Ellipses (`out=...`, which has the same effect as None as an array is always returned), or a 1-element tuple.

Returns**r**

[ndarray] The reduced values. If `out` was supplied, `r` is a reference to `out`.

Notes

A descriptive example:

If `array` is 1-D, the function `ufunc.accumulate(array)` is the same as `ufunc.reduceat(array, indices)[::2]` where `indices` is `range(len(array) - 1)` with a zero placed in every other element: `indices = zeros(2 * len(array) - 1)`, `indices[1::2] = range(1, len(array))`.

Don't be fooled by this attribute's name: `reduceat(array)` is not necessarily smaller than `array`.

Examples

To take the running sum of four successive values:

```
>>> import numpy as np
>>> np.add.reduceat(np.arange(8), [0, 4, 1, 5, 2, 6, 3, 7])[::2]
array([ 6, 10, 14, 18])
```

A 2-D example:

```
>>> x = np.linspace(0, 15, 16).reshape(4, 4)
>>> x
array([[ 0.,  1.,  2.,  3.],
       [ 4.,  5.,  6.,  7.],
       [ 8.,  9., 10., 11.],
       [12., 13., 14., 15.]])
```

```
# reduce such that the result has the following five rows:
# [row1 + row2 + row3]
# [row4]
# [row2]
# [row3]
# [row1 + row2 + row3 + row4]
```

```
>>> np.add.reduceat(x, [0, 3, 1, 2, 0])
array([[12., 15., 18., 21.],
       [12., 13., 14., 15.],
       [ 4.,  5.,  6.,  7.],
       [ 8.,  9., 10., 11.],
       [24., 28., 32., 36.]])
```

```
# reduce such that result has the following two columns:
# [col1 * col2 * col3, col4]
```

```
>>> np.multiply.reduceat(x, [0, 3], 1)
array([[ 0.,  3.],
       [120.,  7.],
       [720., 11.],
       [2184., 15.]])
```

method

`ufunc.resolve_dtypes` (*dtypes*, *, *signature=None*, *casting=None*, *reduction=False*)

Find the dtypes NumPy will use for the operation. Both input and output dtypes are returned and may differ from those provided.

Note: This function always applies NEP 50 rules since it is not provided any actual values. The Python types `int`, `float`, and `complex` thus behave weak and should be passed for “untyped” Python input.

Parameters

dtypes

[tuple of dtypes, None, or literal int, float, complex] The input dtypes for each operand. Output operands can be None, indicating that the dtype must be found.

signature

[tuple of DTypes or None, optional] If given, enforces exact DType (classes) of the specific operand. The `ufunc dtype` argument is equivalent to passing a tuple with only output dtypes set.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] The casting mode when casting is necessary. This is identical to the `ufunc` call casting modes.

reduction

[boolean] If given, the resolution assumes a reduce operation is happening which slightly changes the promotion and type resolution rules. *dtypes* is usually something like `(None, np.dtype("i2"), None)` for reductions (first input is also the output).

Note: The default casting mode is “same_kind”, however, as of NumPy 1.24, NumPy uses “unsafe” for reductions.

Returns

dtypes

[tuple of dtypes] The dtypes which NumPy would use for the calculation. Note that dtypes may not match the passed in ones (casting is necessary).

Examples

This API requires passing dtypes, define them for convenience:

```
>>> import numpy as np
>>> int32 = np.dtype(np.int32)
>>> float32 = np.dtype(np.float32)
```

The typical ufunc call does not pass an output dtype. `numpy.add` has two inputs and one output, so leave the output as `None` (not provided):

```
>>> np.add.resolve_dtypes((int32, float32, None))
(dtype('float64'), dtype('float64'), dtype('float64'))
```

The loop found uses “float64” for all operands (including the output), the first input would be cast.

`resolve_dtypes` supports “weak” handling for Python scalars by passing `int`, `float`, or `complex`:

```
>>> np.add.resolve_dtypes((float32, float, None))
(dtype('float32'), dtype('float32'), dtype('float32'))
```

Where the Python `float` behaves similar to a Python value `0.0` in a ufunc call. (See [NEP 50](#) for details.)

Returns

r

[ndarray or tuple of ndarray] *r* will have the shape that the arrays in *x* broadcast to; if *out* is provided, it will be returned. If not, *r* will be allocated and may contain uninitialized values. If the function has more than one output, then the result will be a tuple of arrays.

Optional keyword arguments

All ufuncs take optional keyword arguments. Most of these represent advanced usage and will not typically be used.

out

The first output can be provided as either a positional or a keyword parameter. Keyword ‘out’ arguments are incompatible with positional ones.

The ‘out’ keyword argument is expected to be a tuple with one entry per output (which can be `None` for arrays to be allocated by the ufunc). For ufuncs with a single output, passing a single array (instead of a tuple holding a single array) is also valid.

If ‘out’ is `None` (the default), a uninitialized output array is created, which will be filled in the ufunc. At the end, this array is returned unless it is zero-dimensional, in which case it is converted to a scalar; this conversion can be avoided by passing in `out=...`. This can also be spelled `out=Ellipsis` if you think that is clearer.

Note that the output is filled only in the places that the broadcast ‘where’ is `True`. If ‘where’ is the scalar `True` (the default), then this corresponds to all elements of the output, but in other cases, the elements not explicitly filled are left with their uninitialized values.

Operations where ufunc input and output operands have memory overlap are defined to be the same as for equivalent operations where there is no memory overlap. Operations affected make temporary copies as needed to eliminate data dependency. As detecting these cases is computationally expensive, a heuristic is used, which may in rare cases result in needless temporary copies. For operations where the data dependency is simple enough for the heuristic to analyze, temporary copies will not be made even if the arrays overlap, if it can be deduced copies are not necessary. As an example, `np.add(a, b, out=a)` will not involve copies.

where

Accepts a boolean array which is broadcast together with the operands. Values of True indicate to calculate the ufunc at that position, values of False indicate to leave the value in the output alone. This argument cannot be used for generalized ufuncs as those take non-scalar input.

Note that if an uninitialized return array is created, values of False will leave those values **uninitialized**.

axes

A list of tuples with indices of axes a generalized ufunc should operate on. For instance, for a signature of $(i, j), (j, k) \rightarrow (i, k)$ appropriate for matrix multiplication, the base elements are two-dimensional matrices and these are taken to be stored in the two last axes of each argument. The corresponding axes keyword would be `[(-2, -1), (-2, -1), (-2, -1)]`. For simplicity, for generalized ufuncs that operate on 1-dimensional arrays (vectors), a single integer is accepted instead of a single-element tuple, and for generalized ufuncs for which all outputs are scalars, the output tuples can be omitted.

axis

A single axis over which a generalized ufunc should operate. This is a short-cut for ufuncs that operate over a single, shared core dimension, equivalent to passing in `axes` with entries of `(axis,)` for each single-core-dimension argument and `()` for all others. For instance, for a signature $(i), (i) \rightarrow ()$, it is equivalent to passing in `axes=[(axis,), (axis,), ()]`.

keepdims

If this is set to *True*, axes which are reduced over will be left in the result as a dimension with size one, so that the result will broadcast correctly against the inputs. This option can only be used for generalized ufuncs that operate on inputs that all have the same number of core dimensions and with outputs that have no core dimensions, i.e., with signatures like $(i), (i) \rightarrow ()$ or $(m, m) \rightarrow ()$. If used, the location of the dimensions in the output can be controlled with `axes` and `axis`.

casting

May be 'no', 'equiv', 'safe', 'same_kind', or 'unsafe'. See [can_cast](#) for explanations of the parameter values.

Provides a policy for what kind of casting is permitted. For compatibility with previous versions of NumPy, this defaults to 'unsafe' for numpy < 1.7. In numpy 1.7 a transition to 'same_kind' was begun where ufuncs produce a DeprecationWarning for calls which are allowed under the 'unsafe' rules, but not under the 'same_kind' rules. From numpy 1.10 and onwards, the default is 'same_kind'.

order

Specifies the calculation iteration order/memory layout of the output array. Defaults to 'K'. 'C' means the output should be C-contiguous, 'F' means F-contiguous, 'A' means F-contiguous if the inputs are F-contiguous and not also not C-contiguous, C-contiguous otherwise, and 'K' means to match the element ordering of the inputs as closely as possible.

dtype

Overrides the DType of the output arrays the same way as the *signature*. This should ensure a matching precision of the calculation. The exact calculation DTypes chosen may depend on the ufunc and the inputs may be cast to this DType to perform the calculation.

subok

Defaults to true. If set to false, the output will always be a strict array, not a subtype.

signature

Either a DType, a tuple of DTypes, or a special signature string indicating the input and output types of a ufunc.

This argument allows the user to specify exact DTypes to be used for the calculation. Casting will be used as necessary. The actual DType of the input arrays is not considered unless *signature* is None for that array.

When all DTypes are fixed, a specific loop is chosen or an error raised if no matching loop exists. If some DTypes are not specified and left None, the behaviour may depend on the ufunc. At this time, a list of available signatures is provided by the **types** attribute of the ufunc. (This list may be missing DTypes not defined by NumPy.)

The *signature* only specifies the DType class/type. For example, it can specify that the operation should be `date-time64` or `float64` operation. It does not specify the `datetime64` time-unit or the `float64` byte-order.

For backwards compatibility this argument can also be provided as *sig*, although the long form is preferred. Note that this should not be confused with the generalized ufunc *signature* that is stored in the **signature** attribute of the of the ufunc object.

Attributes

There are some informational attributes that universal functions possess. None of the attributes can be set.

__doc__	A docstring for each ufunc. The first part of the docstring is dynamically generated from the number of outputs, the name, and the number of inputs. The second part of the docstring is provided at creation time and stored with the ufunc.
__name__	The name of the ufunc.
__signature__	The call signature of the ufunc, as an <code>inspect.Signature</code> object.

<code>ufunc.nin</code>	The number of inputs.
<code>ufunc.nout</code>	The number of outputs.
<code>ufunc.nargs</code>	The number of arguments.
<code>ufunc.ntypes</code>	The number of types.
<code>ufunc.types</code>	Returns a list with types grouped input->output.
<code>ufunc.identity</code>	The identity value.
<code>ufunc.signature</code>	Definition of the core elements a generalized ufunc operates on.

attribute

`ufunc.nin`

The number of inputs.

Data attribute containing the number of arguments the ufunc treats as input.

Examples

```
>>> import numpy as np
>>> np.add.nin
2
>>> np.multiply.nin
2
>>> np.power.nin
2
>>> np.exp.nin
1
```

attribute

`ufunc.nout`

The number of outputs.

Data attribute containing the number of arguments the ufunc treats as output.

Notes

Since all ufuncs can take output arguments, this will always be at least 1.

Examples

```
>>> import numpy as np
>>> np.add.nout
1
>>> np.multiply.nout
1
>>> np.power.nout
1
>>> np.exp.nout
1
```

attribute

ufunc.nargs

The number of arguments.

Data attribute containing the number of arguments the ufunc takes, including optional ones.

Notes

Typically this value will be one more than what you might expect because all ufuncs take the optional “out” argument.

Examples

```
>>> import numpy as np
>>> np.add.nargs
3
>>> np.multiply.nargs
3
>>> np.power.nargs
3
>>> np.exp.nargs
2
```

attribute

ufunc.ntypes

The number of types.

The number of numerical NumPy types - of which there are 18 total - on which the ufunc can operate.

See also:

[numpy.ufunc.types](#)

Examples

```
>>> import numpy as np
>>> np.add.ntypes
22
>>> np.multiply.ntypes
23
>>> np.power.ntypes
21
>>> np.exp.ntypes
10
>>> np.remainder.ntypes
16
```

attribute

ufunc.types

Returns a list with types grouped input->output.

Data attribute listing the data-type “Domain-Range” groupings the ufunc can deliver. The data-types are given using the character codes.

See also:

*numpy.ufunc.otypes***Examples**

```
>>> import numpy as np
>>> np.add.otypes
['??->?', 'bb->b', 'BB->B', 'hh->h', 'HH->H', 'ii->i', 'II->I', ...]
```

```
>>> np.power.otypes
['bb->b', 'BB->B', 'hh->h', 'HH->H', 'ii->i', 'II->I', 'll->l', ...]
```

```
>>> np.exp.otypes
['e->e', 'f->f', 'd->d', 'f->f', 'd->d', 'g->g', 'F->F', 'D->D', 'G->G', 'O->O']
```

```
>>> np.remainder.otypes
['bb->b', 'BB->B', 'hh->h', 'HH->H', 'ii->i', 'II->I', 'll->l', ...]
```

attribute

ufunc.identity

The identity value.

Data attribute containing the identity element for the ufunc, if it has one. If it does not, the attribute value is None.

Examples

```
>>> import numpy as np
>>> np.add.identity
0
>>> np.multiply.identity
1
>>> print(np.power.identity)
None
>>> print(np.exp.identity)
None
```

attribute

ufunc.signature

Definition of the core elements a generalized ufunc operates on.

The signature determines how the dimensions of each input/output array are split into core and loop dimensions:

1. Each dimension in the signature is matched to a dimension of the corresponding passed-in array, starting from the end of the shape tuple.
2. Core dimensions assigned to the same label in the signature must have exactly matching sizes, no broadcasting is performed.
3. The core dimensions are removed from all inputs and the remaining dimensions are broadcast together, defining the loop dimensions.

Notes

Generalized ufuncs are used internally in many linalg functions, and in the testing suite; the examples below are taken from these. For ufuncs that operate on scalars, the signature is `None`, which is equivalent to `()` for every argument.

Examples

```
>>> import numpy as np
>>> np.linalg._umath_linalg.det.signature
' (m,m)-> () '
>>> np.matmul.signature
' (n?,k), (k,m?)-> (n?,m?) '
>>> np.add.signature is None
True # equivalent to ' (), ()-> () '
```

Methods

<code>ufunc.reduce(array[, axis, dtype, out, ...])</code>	Reduces <code>array</code> 's dimension by one, by applying ufunc along one axis.
<code>ufunc.accumulate(array[, axis, dtype, out])</code>	Accumulate the result of applying the operator to all elements.
<code>ufunc.reduceat(array, indices[, axis, ...])</code>	Performs a (local) reduce with specified slices over a single axis.
<code>ufunc.outer(A, B, /, **kwargs)</code>	Apply the ufunc <i>op</i> to all pairs (a, b) with a in <i>A</i> and b in <i>B</i> .
<code>ufunc.at(a, indices[, b])</code>	Performs unbuffered in place operation on operand 'a' for elements specified by 'indices'.

Warning: A reduce-like operation on an array with a data-type that has a range “too small” to handle the result will silently wrap. One should use `dtype` to increase the size of the data-type over which reduction takes place.

1.3.2 Available ufuncs

There are currently more than 60 universal functions defined in `numpy` on one or more types, covering a wide variety of operations. Some of these ufuncs are called automatically on arrays when the relevant infix notation is used (e.g., `add(a, b)` is called internally when `a + b` is written and `a` or `b` is an `ndarray`). Nevertheless, you may still want to use the ufunc call in order to use the optional output argument(s) to place the output(s) in an object (or objects) of your choice.

Recall that each ufunc operates element-by-element. Therefore, each scalar ufunc will be described as if acting on a set of scalar inputs to return a set of scalar outputs.

Note: The ufunc still returns its output(s) even if you use the optional output argument(s).

Math operations

<code>add(x1, x2, /[, out, where, casting, order, ...])</code>	Add arguments element-wise.
<code>subtract(x1, x2, /[, out, where, casting, ...])</code>	Subtract arguments, element-wise.
<code>multiply(x1, x2, /[, out, where, casting, ...])</code>	Multiply arguments element-wise.
<code>matmul(x1, x2, /[, out, casting, order, ...])</code>	Matrix product of two arrays.
<code>divide(x1, x2, /[, out, where, casting, ...])</code>	Divide arguments element-wise.
<code>logaddexp(x1, x2, /[, out, where, casting, ...])</code>	Logarithm of the sum of exponentiations of the inputs.
<code>logaddexp2(x1, x2, /[, out, where, casting, ...])</code>	Logarithm of the sum of exponentiations of the inputs in base-2.
<code>true_divide(x1, x2, /[, out, where, ...])</code>	Divide arguments element-wise.
<code>floor_divide(x1, x2, /[, out, where, ...])</code>	Return the largest integer smaller or equal to the division of the inputs.
<code>negative(x, /[, out, where, casting, order, ...])</code>	Numerical negation, element-wise.
<code>positive(x, /[, out, where, casting, order, ...])</code>	Numerical positive, element-wise.
<code>power(x1, x2, /[, out, where, casting, ...])</code>	First array elements raised to powers from second array, element-wise.
<code>float_power(x1, x2, /[, out, where, ...])</code>	First array elements raised to powers from second array, element-wise.
<code>remainder(x1, x2, /[, out, where, casting, ...])</code>	Returns the element-wise remainder of division.
<code>mod(x1, x2, /[, out, where, casting, order, ...])</code>	Returns the element-wise remainder of division.
<code>fmod(x1, x2, /[, out, where, casting, ...])</code>	Returns the element-wise remainder of division.
<code>divmod(x1, x2[, out1, out2], / [[, out, ...])</code>	Return element-wise quotient and remainder simultaneously.
<code>absolute(x, /[, out, where, casting, order, ...])</code>	Calculate the absolute value element-wise.
<code>fabs(x, /[, out, where, casting, order, ...])</code>	Compute the absolute values element-wise.
<code>rint(x, /[, out, where, casting, order, ...])</code>	Round elements of the array to the nearest integer.
<code>sign(x, /[, out, where, casting, order, ...])</code>	Returns an element-wise indication of the sign of a number.
<code>heaviside(x1, x2, /[, out, where, casting, ...])</code>	Compute the Heaviside step function.
<code>conj(x, /[, out, where, casting, order, ...])</code>	Return the complex conjugate, element-wise.
<code>conjugate(x, /[, out, where, casting, ...])</code>	Return the complex conjugate, element-wise.
<code>exp(x, /[, out, where, casting, order, ...])</code>	Calculate the exponential of all elements in the input array.
<code>exp2(x, /[, out, where, casting, order, ...])</code>	Calculate 2^{**p} for all p in the input array.
<code>log(x, /[, out, where, casting, order, ...])</code>	Natural logarithm, element-wise.
<code>log2(x, /[, out, where, casting, order, ...])</code>	Base-2 logarithm of x .
<code>log10(x, /[, out, where, casting, order, ...])</code>	Return the base 10 logarithm of the input array, element-wise.
<code>expm1(x, /[, out, where, casting, order, ...])</code>	Calculate $\exp(x) - 1$ for all elements in the array.
<code>log1p(x, /[, out, where, casting, order, ...])</code>	Return the natural logarithm of one plus the input array, element-wise.
<code>sqrt(x, /[, out, where, casting, order, ...])</code>	Return the non-negative square-root of an array, element-wise.
<code>square(x, /[, out, where, casting, order, ...])</code>	Return the element-wise square of the input.
<code>cbrt(x, /[, out, where, casting, order, ...])</code>	Return the cube-root of an array, element-wise.
<code>reciprocal(x, /[, out, where, casting, ...])</code>	Return the reciprocal of the argument, element-wise.
<code>gcd(x1, x2, /[, out, where, casting, order, ...])</code>	Returns the greatest common divisor of $ x1 $ and $ x2 $
<code>lcm(x1, x2, /[, out, where, casting, order, ...])</code>	Returns the lowest common multiple of $ x1 $ and $ x2 $

Tip: The optional output arguments can be used to help you save memory for large calculations. If your arrays are

large, complicated expressions can take longer than absolutely necessary due to the creation and (later) destruction of temporary calculation spaces. For example, the expression `G = A * B + C` is equivalent to `T1 = A * B; G = T1 + C; del T1`. It will be more quickly executed as `G = A * B; add(G, C, G)` which is the same as `G = A * B; G += C`.

Trigonometric functions

All trigonometric functions use radians when an angle is called for. The ratio of degrees to radians is $180^\circ/\pi$.

<code>sin(x, /[, out, where, casting, order, ...])</code>	Trigonometric sine, element-wise.
<code>cos(x, /[, out, where, casting, order, ...])</code>	Cosine element-wise.
<code>tan(x, /[, out, where, casting, order, ...])</code>	Compute tangent element-wise.
<code>arcsin(x, /[, out, where, casting, order, ...])</code>	Inverse sine, element-wise.
<code>arccos(x, /[, out, where, casting, order, ...])</code>	Trigonometric inverse cosine, element-wise.
<code>arctan(x, /[, out, where, casting, order, ...])</code>	Trigonometric inverse tangent, element-wise.
<code>arctan2(x1, x2, /[, out, where, casting, ...])</code>	Element-wise arc tangent of $x1/x2$ choosing the quadrant correctly.
<code>hypot(x1, x2, /[, out, where, casting, ...])</code>	Given the "legs" of a right triangle, return its hypotenuse.
<code>sinh(x, /[, out, where, casting, order, ...])</code>	Hyperbolic sine, element-wise.
<code>cosh(x, /[, out, where, casting, order, ...])</code>	Hyperbolic cosine, element-wise.
<code>tanh(x, /[, out, where, casting, order, ...])</code>	Hyperbolic tangent, element-wise.
<code>arcsinh(x, /[, out, where, casting, order, ...])</code>	Inverse hyperbolic sine, element-wise.
<code>arccosh(x, /[, out, where, casting, order, ...])</code>	Inverse hyperbolic cosine, element-wise.
<code>arctanh(x, /[, out, where, casting, order, ...])</code>	Inverse hyperbolic tangent, element-wise.
<code>degrees(x, /[, out, where, casting, order, ...])</code>	Convert angles from radians to degrees.
<code>radians(x, /[, out, where, casting, order, ...])</code>	Convert angles from degrees to radians.
<code>deg2rad(x, /[, out, where, casting, order, ...])</code>	Convert angles from degrees to radians.
<code>rad2deg(x, /[, out, where, casting, order, ...])</code>	Convert angles from radians to degrees.

Bit-twiddling functions

These function all require integer arguments and they manipulate the bit-pattern of those arguments.

<code>bitwise_and(x1, x2, /[, out, where, ...])</code>	Compute the bit-wise AND of two arrays element-wise.
<code>bitwise_or(x1, x2, /[, out, where, casting, ...])</code>	Compute the bit-wise OR of two arrays element-wise.
<code>bitwise_xor(x1, x2, /[, out, where, ...])</code>	Compute the bit-wise XOR of two arrays element-wise.
<code>invert(x, /[, out, where, casting, order, ...])</code>	Compute bit-wise inversion, or bit-wise NOT, element-wise.
<code>left_shift(x1, x2, /[, out, where, casting, ...])</code>	Shift the bits of an integer to the left.
<code>right_shift(x1, x2, /[, out, where, ...])</code>	Shift the bits of an integer to the right.

Comparison functions

<code>greater(x1, x2, /[, out, where, casting, ...])</code>	Return the truth value of $(x1 > x2)$ element-wise.
<code>greater_equal(x1, x2, /[, out, where, ...])</code>	Return the truth value of $(x1 \geq x2)$ element-wise.
<code>less(x1, x2, /[, out, where, casting, ...])</code>	Return the truth value of $(x1 < x2)$ element-wise.
<code>less_equal(x1, x2, /[, out, where, casting, ...])</code>	Return the truth value of $(x1 \leq x2)$ element-wise.
<code>not_equal(x1, x2, /[, out, where, casting, ...])</code>	Return $(x1 \neq x2)$ element-wise.
<code>equal(x1, x2, /[, out, where, casting, ...])</code>	Return $(x1 == x2)$ element-wise.

Warning: Do not use the Python keywords `and` and `or` to combine logical array expressions. These keywords will test the truth value of the entire array (not element-by-element as you might expect). Use the bitwise operators `&` and `|` instead.

<code>logical_and(x1, x2, /[, out, where, ...])</code>	Compute the truth value of $x1$ AND $x2$ element-wise.
<code>logical_or(x1, x2, /[, out, where, casting, ...])</code>	Compute the truth value of $x1$ OR $x2$ element-wise.
<code>logical_xor(x1, x2, /[, out, where, ...])</code>	Compute the truth value of $x1$ XOR $x2$, element-wise.
<code>logical_not(x, /[, out, where, casting, ...])</code>	Compute the truth value of NOT x element-wise.

Warning: The bit-wise operators `&` and `|` are the proper way to perform element-by-element array comparisons. Be sure you understand the operator precedence: $(a > 2) \& (a < 5)$ is the proper syntax because $a > 2 \& a < 5$ will result in an error due to the fact that $2 \& a$ is evaluated first.

<code>maximum(x1, x2, /[, out, where, casting, ...])</code>	Element-wise maximum of array elements.
---	---

Tip: The Python function `max()` will find the maximum over a one-dimensional array, but it will do so using a slower sequence interface. The reduce method of the maximum ufunc is much faster. Also, the `max()` method will not give answers you might expect for arrays with greater than one dimension. The reduce method of minimum also allows you to compute a total minimum over an array.

<code>minimum(x1, x2, /[, out, where, casting, ...])</code>	Element-wise minimum of array elements.
---	---

Warning: the behavior of `maximum(a, b)` is different than that of `max(a, b)`. As a ufunc, `maximum(a, b)` performs an element-by-element comparison of a and b and chooses each element of the result according to which element in the two arrays is larger. In contrast, `max(a, b)` treats the objects a and b as a whole, looks at the (total) truth value of $a > b$ and uses it to return either a or b (as a whole). A similar difference exists between `minimum(a, b)` and `min(a, b)`.

<code>fmax(x1, x2, /[, out, where, casting, ...])</code>	Element-wise maximum of array elements.
<code>fmin(x1, x2, /[, out, where, casting, ...])</code>	Element-wise minimum of array elements.

Floating functions

Recall that all of these functions work element-by-element over an array, returning an array output. The description details only a single operation.

<code>isfinite(x, /[, out, where, casting, order, ...])</code>	Test element-wise for finiteness (not infinity and not Not a Number).
<code>isinf(x, /[, out, where, casting, order, ...])</code>	Test element-wise for positive or negative infinity.
<code>isnan(x, /[, out, where, casting, order, ...])</code>	Test element-wise for NaN and return result as a boolean array.
<code>isnat(x, /[, out, where, casting, order, ...])</code>	Test element-wise for NaT (not a time) and return result as a boolean array.
<code>fabs(x, /[, out, where, casting, order, ...])</code>	Compute the absolute values element-wise.
<code>signbit(x, /[, out, where, casting, order, ...])</code>	Returns element-wise True where signbit is set (less than zero).
<code>copysign(x1, x2, /[, out, where, casting, ...])</code>	Change the sign of x1 to that of x2, element-wise.
<code>nextafter(x1, x2, /[, out, where, casting, ...])</code>	Return the next floating-point value after x1 towards x2, element-wise.
<code>spacing(x, /[, out, where, casting, order, ...])</code>	Return the distance between x and the nearest adjacent number.
<code>modf(x[, out1, out2], / [[, out, where, ...])</code>	Return the fractional and integral parts of an array, element-wise.
<code>ldexp(x1, x2, /[, out, where, casting, ...])</code>	Returns $x1 * 2^{x2}$, element-wise.
<code>frexp(x[, out1, out2], / [[, out, where, ...])</code>	Decompose the elements of x into mantissa and twos exponent.
<code>fmod(x1, x2, /[, out, where, casting, ...])</code>	Returns the element-wise remainder of division.
<code>floor(x, /[, out, where, casting, order, ...])</code>	Return the floor of the input, element-wise.
<code>ceil(x, /[, out, where, casting, order, ...])</code>	Return the ceiling of the input, element-wise.
<code>trunc(x, /[, out, where, casting, order, ...])</code>	Return the truncated value of the input, element-wise.

1.4 Routines and objects by topic

In this chapter, routine docstrings are presented, grouped by functionality. Many docstrings contain example code, which demonstrates basic usage of the routine.

A convenient way to execute examples is the `%doctest_mode` mode of IPython, which allows for pasting of multi-line examples and preserves indentation.

1.4.1 Constants

NumPy includes several constants:

`numpy.e`

Euler's number, base of natural logarithms, Napier's constant.

`e = 2.71828182845904523536028747135266249775724709369995...`

See Also

`exp` : Exponential function
`log` : Natural logarithm

References

https://en.wikipedia.org/wiki/E_%28mathematical_constant%29

`numpy.euler_gamma`

$\gamma = 0.5772156649015328606065120900824024310421\dots$

References

https://en.wikipedia.org/wiki/Euler%27s_constant

`numpy.inf`

IEEE 754 floating point representation of (positive) infinity.

Returns

y

[float] A floating point representation of positive infinity.

See Also

`isinf` : Shows which elements are positive or negative infinity

`isposinf` : Shows which elements are positive infinity

`isneginf` : Shows which elements are negative infinity

`isnan` : Shows which elements are Not a Number

`isfinite` : Shows which elements are finite (not one of Not a Number, positive infinity and negative infinity)

Notes

NumPy uses the IEEE Standard for Binary Floating-Point for Arithmetic (IEEE 754). This means that Not a Number is not equivalent to infinity. Also that positive infinity is not equivalent to negative infinity. But infinity is equivalent to positive infinity.

Examples

```
>>> import numpy as np
>>> np.inf
inf
>>> np.array([1]) / 0.
array([inf])
```

`numpy.nan`

IEEE 754 floating point representation of Not a Number (NaN).

Returns

y : A floating point representation of Not a Number.

See Also

isnan : Shows which elements are Not a Number.

isfinite : Shows which elements are finite (not one of Not a Number, positive infinity and negative infinity)

Notes

NumPy uses the IEEE Standard for Binary Floating-Point for Arithmetic (IEEE 754). This means that Not a Number is not equivalent to infinity.

Examples

```
>>> import numpy as np
>>> np.nan
nan
>>> np.log(-1)
np.float64(nan)
>>> np.log([-1, 1, 2])
array([      nan, 0.        , 0.69314718])
```

numpy.**newaxis**

A convenient alias for None, useful for indexing arrays.

Examples

```
>>> import numpy as np
>>> np.newaxis is None
True
>>> x = np.arange(3)
>>> x
array([0, 1, 2])
>>> x[:, np.newaxis]
array([[0],
       [1],
       [2]])
>>> x[:, np.newaxis, np.newaxis]
array([[[0]],
       [[1]],
       [[2]])]
>>> x[:, np.newaxis] * x
array([[0, 0, 0],
       [0, 1, 2],
       [0, 2, 4]])
```

Outer product, same as `outer(x, y)`:

```
>>> y = np.arange(3, 6)
>>> x[:, np.newaxis] * y
array([[ 0,  0,  0],
       [ 3,  4,  5],
       [ 6,  8, 10]])
```

`x[np.newaxis, :]` is equivalent to `x[np.newaxis]` and `x[None]`:

```
>>> x[np.newaxis, :].shape
(1, 3)
>>> x[np.newaxis].shape
(1, 3)
>>> x[None].shape
(1, 3)
>>> x[:, np.newaxis].shape
(3, 1)
```

`numpy.pi`

```
pi = 3.1415926535897932384626433...
```

1.4.2 Array creation routines

See also:

Array creation

From shape or value

<code>empty(shape[, dtype, order, device, like])</code>	Return a new array of given shape and type, without initializing entries.
<code>empty_like(prototype, /[, dtype, order, ...])</code>	Return a new array with the same shape and type as a given array.
<code>eye(N[, M, k, dtype, order, device, like])</code>	Return a 2-D array with ones on the diagonal and zeros elsewhere.
<code>identity(n[, dtype, like])</code>	Return the identity array.
<code>ones(shape[, dtype, order, device, like])</code>	Return a new array of given shape and type, filled with ones.
<code>ones_like(a[, dtype, order, subok, shape, ...])</code>	Return an array of ones with the same shape and type as a given array.
<code>zeros(shape[, dtype, order, device, like])</code>	Return a new array of given shape and type, filled with zeros.
<code>zeros_like(a[, dtype, order, subok, shape, ...])</code>	Return an array of zeros with the same shape and type as a given array.
<code>full(shape, fill_value[, dtype, order, ...])</code>	Return a new array of given shape and type, filled with <i>fill_value</i> .
<code>full_like(a, fill_value[, dtype, order, ...])</code>	Return a full array with the same shape and type as a given array.

`numpy.empty(shape, dtype=None, order='C', *, device=None, like=None)`

Return a new array of given shape and type, without initializing entries.

Parameters

shape

[int or tuple of int] Shape of the empty array, e.g., (2, 3) or 2.

dtype

[data-type, optional] Desired output data-type for the array, e.g. `numpy.int8`. Default is `numpy.float64`.

order

[{'C', 'F'}, optional, default: 'C'] Whether to store multi-dimensional data in row-major (C-style) or column-major (Fortran-style) order in memory.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[ndarray] Array of uninitialized (arbitrary) data of the given shape, dtype, and order. Object arrays will be initialized to None.

See also:

`empty_like`

Return an empty array with shape and type of input.

`ones`

Return a new array setting values to one.

`zeros`

Return a new array setting values to zero.

`full`

Return a new array of given shape filled with value.

Notes

Unlike other array creation functions (e.g. `zeros`, `ones`, `full`), `empty` does not initialize the values of the array, and may therefore be marginally faster. However, the values stored in the newly allocated array are arbitrary. For reproducible behavior, be sure to set each element of the array before reading.

Examples

```
>>> import numpy as np
>>> np.empty([2, 2])
array([[ -9.74499359e+001,   6.69583040e-309],
       [  2.13182611e-314,   3.06959433e-309]])      #uninitialized
```

```
>>> np.empty([2, 2], dtype=np.int_)
array([[ -1073741821, -1067949133],
       [  496041986,   19249760]])      #uninitialized
```

`numpy.empty_like` (*prototype*, /, *dtype=None*, *order='K'*, *subok=True*, *shape=None*, *, *device=None*)

Return a new array with the same shape and type as a given array.

Parameters

prototype

[array_like] The shape and data-type of *prototype* define these same attributes of the returned array.

dtype

[data-type, optional] Overrides the data type of the result.

order

[{'C', 'F', 'A', or 'K'}, optional] Overrides the memory layout of the result. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *prototype* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *prototype* as closely as possible.

subok

[bool, optional.] If True, then the newly created array will use the sub-class type of *prototype*, otherwise it will be a base-class array. Defaults to True.

shape

[int or sequence of ints, optional.] Overrides the shape of the result. If *order*='K' and the number of dimensions is unchanged, will try to keep order, otherwise, *order*='C' is implied.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

Returns

out

[ndarray] Array of uninitialized (arbitrary) data with the same shape and type as *prototype*.

See also:

ones_like

Return an array of ones with shape and type of input.

zeros_like

Return an array of zeros with shape and type of input.

full_like

Return a new array with shape of input filled with value.

empty

Return a new uninitialized array.

Notes

Unlike other array creation functions (e.g. `zeros_like`, `ones_like`, `full_like`), `empty_like` does not initialize the values of the array, and may therefore be marginally faster. However, the values stored in the newly allocated array are arbitrary. For reproducible behavior, be sure to set each element of the array before reading.

Examples

```
>>> import numpy as np
>>> a = ([1,2,3], [4,5,6])           # a is array-like
>>> np.empty_like(a)
array([[ -1073741821, -1073741821,          3],      # uninitialized
       [          0,          0, -1073741821]])
>>> a = np.array([[1., 2., 3.], [4.,5.,6.]])
>>> np.empty_like(a)
array([[ -2.00000715e+000,  1.48219694e-323, -2.00000572e+000], # uninitialized
       [  4.38791518e-305, -2.00000715e+000,  4.17269252e-309]])
```

`numpy.eye(N, M=None, k=0, dtype=<class 'float'>, order='C', *, device=None, like=None)`

Return a 2-D array with ones on the diagonal and zeros elsewhere.

Parameters

N

[int] Number of rows in the output.

M

[int, optional] Number of columns in the output. If None, defaults to *N*.

k

[int, optional] Index of the diagonal: 0 (the default) refers to the main diagonal, a positive value refers to an upper diagonal, and a negative value to a lower diagonal.

dtype

[data-type, optional] Data-type of the returned array.

order

[{'C', 'F'}, optional] Whether the output should be stored in row-major (C-style) or column-major (Fortran-style) order in memory.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

I

[ndarray of shape (N,M)] An array where all elements are equal to zero, except for the *k*-th diagonal, whose values are equal to one.

See also:

identity

(almost) equivalent function

diag

diagonal 2-D array from a 1-D array specified by the user.

Examples

```
>>> import numpy as np
>>> np.eye(2, dtype=np.int_)
array([[1, 0],
       [0, 1]])
>>> np.eye(3, k=1)
array([[0., 1., 0.],
       [0., 0., 1.],
       [0., 0., 0.]])
```

`numpy.identity` (*n*, *dtype=None*, *, *like=None*)

Return the identity array.

The identity array is a square array with ones on the main diagonal.

Parameters

n

[int] Number of rows (and columns) in $n \times n$ output.

dtype

[data-type, optional] Data-type of the output. Defaults to `float`.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[ndarray] $n \times n$ array with its main diagonal set to one, and all other elements 0.

Examples

```
>>> import numpy as np
>>> np.identity(3)
array([[1., 0., 0.],
       [0., 1., 0.],
       [0., 0., 1.]])
```

`numpy.ones` (*shape*, *dtype=None*, *order='C'*, *, *device=None*, *like=None*)

Return a new array of given shape and type, filled with ones.

Parameters

shape

[int or sequence of ints] Shape of the new array, e.g., (2, 3) or 2.

dtype

[data-type, optional] The desired data-type for the array, e.g., `numpy.int8`. Default is `numpy.float64`.

order

[{'C', 'F'}, optional, default: C] Whether to store multi-dimensional data in row-major (C-style) or column-major (Fortran-style) order in memory.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns**out**

[ndarray] Array of ones with the given shape, dtype, and order.

See also:**`ones_like`**

Return an array of ones with shape and type of input.

`empty`

Return a new uninitialized array.

`zeros`

Return a new array setting values to zero.

`full`

Return a new array of given shape filled with value.

Examples

```
>>> import numpy as np
>>> np.ones(5)
array([1., 1., 1., 1., 1.])
```

```
>>> np.ones((5,), dtype=np.int_)
array([1, 1, 1, 1, 1])
```

```
>>> np.ones((2, 1))
array([[1.],
       [1.]])
```

```
>>> s = (2,2)
>>> np.ones(s)
array([[1.,  1.],
       [1.,  1.]])
```

`numpy.ones_like(a, dtype=None, order='K', subok=True, shape=None, *, device=None)`

Return an array of ones with the same shape and type as a given array.

Parameters

a

[array_like] The shape and data-type of *a* define these same attributes of the returned array.

dtype

[data-type, optional] Overrides the data type of the result.

order

[{'C', 'F', 'A', or 'K'}, optional] Overrides the memory layout of the result. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *a* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *a* as closely as possible.

subok

[bool, optional.] If True, then the newly created array will use the sub-class type of *a*, otherwise it will be a base-class array. Defaults to True.

shape

[int or sequence of ints, optional.] Overrides the shape of the result. If order='K' and the number of dimensions is unchanged, will try to keep order, otherwise, order='C' is implied.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

Returns

out

[ndarray] Array of ones with the same shape and type as *a*.

See also:

[*empty_like*](#)

Return an empty array with shape and type of input.

[*zeros_like*](#)

Return an array of zeros with shape and type of input.

[*full_like*](#)

Return a new array with shape of input filled with value.

[*ones*](#)

Return a new array setting values to one.

Examples

```
>>> import numpy as np
>>> x = np.arange(6)
>>> x = x.reshape((2, 3))
>>> x
array([[0, 1, 2],
       [3, 4, 5]])
>>> np.ones_like(x)
array([[1, 1, 1],
       [1, 1, 1]])
```

```
>>> y = np.arange(3, dtype=np.float64)
>>> y
array([0., 1., 2.])
>>> np.ones_like(y)
array([1., 1., 1.])
```

`numpy.zeros` (*shape*, *dtype=None*, *order='C'*, *, *device=None*, *like=None*)

Return a new array of given shape and type, filled with zeros.

Parameters

shape

[int or tuple of ints] Shape of the new array, e.g., (2, 3) or 2.

dtype

[data-type, optional] The desired data-type for the array, e.g., `numpy.int8`. Default is `numpy.float64`.

order

[{'C', 'F'}, optional, default: 'C'] Whether to store multi-dimensional data in row-major (C-style) or column-major (Fortran-style) order in memory.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[ndarray] Array of zeros with the given shape, dtype, and order.

See also:

`zeros_like`

Return an array of zeros with shape and type of input.

`empty`

Return a new uninitialized array.

ones

Return a new array setting values to one.

full

Return a new array of given shape filled with value.

Examples

```
>>> import numpy as np
>>> np.zeros(5)
array([ 0.,  0.,  0.,  0.,  0.]
```

```
>>> np.zeros((5,), dtype=np.int_)
array([0, 0, 0, 0, 0])
```

```
>>> np.zeros((2, 1))
array([[ 0.],
       [ 0.]])
```

```
>>> s = (2,2)
>>> np.zeros(s)
array([[ 0.,  0.],
       [ 0.,  0.]])
```

```
>>> np.zeros((2,), dtype=[('x', 'i4'), ('y', 'i4')]) # custom dtype
array([(0, 0), (0, 0)],
      dtype=[('x', '<i4'), ('y', '<i4')])
```

`numpy.zeros_like(a, dtype=None, order='K', subok=True, shape=None, *, device=None)`

Return an array of zeros with the same shape and type as a given array.

Parameters**a**

[array_like] The shape and data-type of *a* define these same attributes of the returned array.

dtype

[data-type, optional] Overrides the data type of the result.

order

[{'C', 'F', 'A', or 'K'}, optional] Overrides the memory layout of the result. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *a* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *a* as closely as possible.

subok

[bool, optional.] If True, then the newly created array will use the sub-class type of *a*, otherwise it will be a base-class array. Defaults to True.

shape

[int or sequence of ints, optional.] Overrides the shape of the result. If order='K' and the number of dimensions is unchanged, will try to keep order, otherwise, order='C' is implied.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

Returns**out**[ndarray] Array of zeros with the same shape and type as *a*.**See also:*****empty_like***

Return an empty array with shape and type of input.

ones_like

Return an array of ones with shape and type of input.

full_like

Return a new array with shape of input filled with value.

zeros

Return a new array setting values to zero.

Examples

```
>>> import numpy as np
>>> x = np.arange(6)
>>> x = x.reshape((2, 3))
>>> x
array([[0, 1, 2],
       [3, 4, 5]])
>>> np.zeros_like(x)
array([[0, 0, 0],
       [0, 0, 0]])
```

```
>>> y = np.arange(3, dtype=np.float64)
>>> y
array([0., 1., 2.])
>>> np.zeros_like(y)
array([0., 0., 0.])
```

`numpy.full` (*shape*, *fill_value*, *dtype=None*, *order='C'*, **, device=None*, *like=None*)

Return a new array of given shape and type, filled with *fill_value*.**Parameters****shape**

[int or sequence of ints] Shape of the new array, e.g., (2, 3) or 2.

fill_value

[scalar or array_like] Fill value.

dtype

[data-type, optional]

The desired data-type for the array The default, None, means`np.array(fill_value).dtype`.**order**

[['C', 'F'], optional] Whether to store multidimensional data in C- or Fortran-contiguous (row- or column-wise) order in memory.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns**out**

[ndarray] Array of *fill_value* with the given shape, dtype, and order.

See also:***full_like***

Return a new array with shape of input filled with value.

empty

Return a new uninitialized array.

ones

Return a new array setting values to one.

zeros

Return a new array setting values to zero.

Examples

```
>>> import numpy as np
>>> np.full((2, 2), np.inf)
array([[inf, inf],
       [inf, inf]])
>>> np.full((2, 2), 10)
array([[10, 10],
       [10, 10]])
```

```
>>> np.full((2, 2), [1, 2])
array([[1, 2],
       [1, 2]])
```

`numpy.full_like(a, fill_value, dtype=None, order='K', subok=True, shape=None, *, device=None)`

Return a full array with the same shape and type as a given array.

Parameters**a**

[array_like] The shape and data-type of *a* define these same attributes of the returned array.

fill_value

[array_like] Fill value.

dtype

[data-type, optional] Overrides the data type of the result.

order

[{'C', 'F', 'A', or 'K'}, optional] Overrides the memory layout of the result. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *a* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *a* as closely as possible.

subok

[bool, optional.] If True, then the newly created array will use the sub-class type of *a*, otherwise it will be a base-class array. Defaults to True.

shape

[int or sequence of ints, optional.] Overrides the shape of the result. If order='K' and the number of dimensions is unchanged, will try to keep order, otherwise, order='C' is implied.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

Returns**out**

[ndarray] Array of *fill_value* with the same shape and type as *a*.

See also:***empty_like***

Return an empty array with shape and type of input.

ones_like

Return an array of ones with shape and type of input.

zeros_like

Return an array of zeros with shape and type of input.

full

Return a new array of given shape filled with value.

Examples

```
>>> import numpy as np
>>> x = np.arange(6, dtype=np.int_)
>>> np.full_like(x, 1)
array([1, 1, 1, 1, 1, 1])
>>> np.full_like(x, 0.1)
array([0, 0, 0, 0, 0, 0])
>>> np.full_like(x, 0.1, dtype=np.float64)
array([0.1, 0.1, 0.1, 0.1, 0.1, 0.1])
>>> np.full_like(x, np.nan, dtype=np.float64)
array([nan, nan, nan, nan, nan, nan])
```

```
>>> y = np.arange(6, dtype=np.float64)
>>> np.full_like(y, 0.1)
array([0.1, 0.1, 0.1, 0.1, 0.1, 0.1])
```

```
>>> y = np.zeros([2, 2, 3], dtype=np.int_)
>>> np.full_like(y, [0, 0, 255])
array([[[ 0,  0, 255],
```

(continues on next page)

(continued from previous page)

```
[ 0, 0, 255]],
[[ 0, 0, 255],
 [ 0, 0, 255]])
```

From existing data

<code>array(object[, dtype, copy, order, subok, ...])</code>	Create an array.
<code>asarray(a[, dtype, order, device, copy, like])</code>	Convert the input to an array.
<code>asanyarray(a[, dtype, order, device, copy, like])</code>	Convert the input to an ndarray, but pass ndarray subclasses through.
<code>ascontiguousarray(a[, dtype, like])</code>	Return a contiguous array (ndim >= 1) in memory (C order).
<code>asmatrix(data[, dtype])</code>	Interpret the input as a matrix.
<code>astype(x, dtype, /, *[, copy, device])</code>	Copies an array to a specified data type.
<code>copy(a[, order, subok])</code>	Return an array copy of the given object.
<code>frombuffer(buffer[, dtype, count, offset, like])</code>	Interpret a buffer as a 1-dimensional array.
<code>from_dlpack(x, /, *[, device, copy])</code>	Create a NumPy array from an object implementing the <code>__dlpack__</code> protocol.
<code>fromfile(file[, dtype, count, sep, offset, like])</code>	Construct an array from data in a text or binary file.
<code>fromfunction(function, shape, *[, dtype, like])</code>	Construct an array by executing a function over each coordinate.
<code>fromiter(iter, dtype[, count, like])</code>	Create a new 1-dimensional array from an iterable object.
<code>fromstring(string[, dtype, count, like])</code>	A new 1-D array initialized from text data in a string.
<code>loadtxt(fname[, dtype, comments, delimiter, ...])</code>	Load data from a text file.

`numpy.array (object, dtype=None, *, copy=True, order='K', subok=False, ndmin=0, ndmax=0, like=None)`

Create an array.

Parameters

object

[array_like] An array, any object exposing the array interface, an object whose `__array__` method returns an array, or any (nested) sequence. If object is a scalar, a 0-dimensional array containing object is returned.

dtype

[data-type, optional] The desired data-type for the array. If not given, NumPy will try to use a default dtype that can represent the values (by applying promotion rules when necessary.)

copy

[bool, optional] If `True` (default), then the array data is copied. If `None`, a copy will only be made if `__array__` returns a copy, if obj is a nested sequence, or if a copy is needed to satisfy any of the other requirements (dtype, order, etc.). Note that any copy of the data is shallow, i.e., for arrays with object dtype, the new array will point to the same objects. See Examples for `ndarray.copy`. For `False` it raises a `ValueError` if a copy cannot be avoided. Default: `True`.

order

[{'K', 'A', 'C', 'F'}, optional] Specify the memory layout of the array. If object is not an array, the newly created array will be in C order (row major) unless 'F' is specified, in which case it will be in Fortran order (column major). If object is an array the following holds.

order	no copy	copy=True
'K'	unchanged	F & C order preserved, otherwise most similar order
'A'	unchanged	F order if input is F and not C, otherwise C order
'C'	C order	C order
'F'	F order	F order

When `copy=None` and a copy is made for other reasons, the result is the same as if `copy=True`, with some exceptions for 'A', see the Notes section. The default order is 'K'.

subok

[bool, optional] If True, then sub-classes will be passed-through, otherwise the returned array will be forced to be a base-class array (default).

ndmin

[int, optional] Specifies the minimum number of dimensions that the resulting array should have. Ones will be prepended to the shape as needed to meet this requirement.

ndmax

[int, optional] Specifies the maximum number of dimensions to create when inferring shape from nested sequences. By default (`ndmax=0`), NumPy recurses through all nesting levels (up to the compile-time constant `NPY_MAXDIMS`). Setting `ndmax` stops recursion at the specified depth, preserving deeper nested structures as objects instead of promoting them to higher-dimensional arrays. In this case, `dtype=np.object_` is required.

New in version 2.4.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns**out**

[ndarray] An array object satisfying the specified requirements.

See also:***empty_like***

Return an empty array with shape and type of input.

ones_like

Return an array of ones with shape and type of input.

zeros_like

Return an array of zeros with shape and type of input.

full_like

Return a new array with shape of input filled with value.

empty

Return a new uninitialized array.

ones

Return a new array setting values to one.

zeros

Return a new array setting values to zero.

full

Return a new array of given shape filled with value.

copy

Return an array copy of the given object.

Notes

When order is 'A' and object is an array in neither 'C' nor 'F' order, and a copy is forced by a change in dtype, then the order of the result is not necessarily 'C' as expected. This is likely a bug.

Examples

```
>>> import numpy as np
>>> np.array([1, 2, 3])
array([1, 2, 3])
```

Upcasting:

```
>>> np.array([1, 2, 3.0])
array([ 1.,  2.,  3.])
```

More than one dimension:

```
>>> np.array([[1, 2], [3, 4]])
array([[1, 2],
       [3, 4]])
```

Minimum dimensions 2:

```
>>> np.array([1, 2, 3], ndmin=2)
array([[1, 2, 3]])
```

Type provided:

```
>>> np.array([1, 2, 3], dtype=np.complex128)
array([ 1.+0.j,  2.+0.j,  3.+0.j])
```

Data-type consisting of more than one element:

```
>>> x = np.array([(1,2), (3,4)], dtype=[('a', '<i4'), ('b', '<i4')])
>>> x['a']
array([1, 3], dtype=int32)
```

Creating an array from sub-classes:

```
>>> np.array(np.asmatrix('1 2; 3 4'))
array([[1, 2],
       [3, 4]])
```

```
>>> np.array(np.asmatrix('1 2; 3 4'), subok=True)
matrix([[1, 2],
        [3, 4]])
```

Limiting the maximum dimensions with `ndmax`:

```
>>> a = np.array([[1, 2], [3, 4]], dtype=np.object_, ndmax=2)
>>> a
array([[1, 2],
       [3, 4]], dtype=object)
>>> a.shape
(2, 2)
```

```
>>> b = np.array([[1, 2], [3, 4]], dtype=np.object_, ndmax=1)
>>> b
array([list([1, 2]), list([3, 4])], dtype=object)
>>> b.shape
(2,)
```

`numpy.asarray(a, dtype=None, order=None, *, device=None, copy=None, like=None)`

Convert the input to an array.

Parameters

a

[array_like] Input data, in any form that can be converted to an array. This includes lists, lists of tuples, tuples, tuples of tuples, tuples of lists and ndarrays.

dtype

[data-type, optional] By default, the data-type is inferred from the input data.

order

[{'C', 'F', 'A', 'K'}, optional] The memory layout of the output. 'C' gives a row-major layout (C-style), 'F' gives a column-major layout (Fortran-style). 'C' and 'F' will copy if needed to ensure the output format. 'A' (any) is equivalent to 'F' if input a is non-contiguous or Fortran-contiguous, otherwise, it is equivalent to 'C'. Unlike 'C' or 'F', 'A' does not ensure that the result is contiguous. 'K' (keep) is the default and preserves the input order for the output.

device

[str, optional] The device on which to place the created array. Default: `None`. For Array-API interoperability only, so must be `"cpu"` if passed.

New in version 2.0.0.

copy

[bool, optional] If `True`, then the object is copied. If `None` then the object is copied only if needed, i.e. if `__array__` returns a copy, if `obj` is a nested sequence, or if a copy is needed to satisfy any of the other requirements (`dtype`, `order`, etc.). For `False` it raises a `ValueError` if a copy cannot be avoided. Default: `None`.

New in version 2.0.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[ndarray] Array interpretation of `a`. No copy is performed if the input is already an ndarray with matching `dtype` and `order`. If `a` is a subclass of ndarray, a base class ndarray is returned.

See also:

asanyarray

Similar function which passes through subclasses.

ascontiguousarray

Convert input to a contiguous array.

asfortranarray

Convert input to an ndarray with column-major memory order.

asarray_chkfinite

Similar function which checks input for NaNs and Infs.

fromiter

Create an array from an iterator.

fromfunction

Construct an array by executing a function on grid positions.

Examples

Convert a list into an array:

```
>>> a = [1, 2]
>>> import numpy as np
>>> np.asarray(a)
array([1, 2])
```

Existing arrays are not copied:

```
>>> a = np.array([1, 2])
>>> np.asarray(a) is a
True
```

If *dtype* is set, array is copied only if dtype does not match:

```
>>> a = np.array([1, 2], dtype=np.float32)
>>> np.shares_memory(np.asarray(a, dtype=np.float32), a)
True
>>> np.shares_memory(np.asarray(a, dtype=np.float64), a)
False
```

Contrary to *asanyarray*, ndarray subclasses are not passed through:

```
>>> isinstance(np.recarray, np.ndarray)
True
>>> a = np.array([(1., 2), (3., 4)], dtype='f4,i4').view(np.recarray)
>>> np.asarray(a) is a
False
>>> np.asanyarray(a) is a
True
```

`numpy.asarray(a, dtype=None, order=None, *, device=None, copy=None, like=None)`

Convert the input to an ndarray, but pass ndarray subclasses through.

Parameters

a

[array_like] Input data, in any form that can be converted to an array. This includes scalars, lists, lists of tuples, tuples, tuples of tuples, tuples of lists, and ndarrays.

dtype

[data-type, optional] By default, the data-type is inferred from the input data.

order

[{'C', 'F', 'A', 'K'}, optional] The memory layout of the output. 'C' gives a row-major layout (C-style), 'F' gives a column-major layout (Fortran-style). 'C' and 'F' will copy if needed to ensure the output format. 'A' (any) is equivalent to 'F' if input *a* is non-contiguous or Fortran-contiguous, otherwise, it is equivalent to 'C'. Unlike 'C' or 'F', 'A' does not ensure that the result is contiguous. 'K' (keep) preserves the input order for the output. 'C' is the default.

device

[str, optional] The device on which to place the created array. Default: `None`. For Array-API interoperability only, so must be `"cpu"` if passed.

New in version 2.1.0.

copy

[bool, optional] If `True`, then the object is copied. If `None` then the object is copied only if needed, i.e. if `__array__` returns a copy, if *obj* is a nested sequence, or if a copy is needed to satisfy any of the other requirements (`dtype`, `order`, etc.). For `False` it raises a `ValueError` if a copy cannot be avoided. Default: `None`.

New in version 2.1.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[ndarray or an ndarray subclass] Array interpretation of *a*. If *a* is an ndarray or a subclass of ndarray, it is returned as-is and no copy is performed.

See also:

asarray

Similar function which always returns ndarrays.

ascontiguousarray

Convert input to a contiguous array.

asfortranarray

Convert input to an ndarray with column-major memory order.

asarray_chkfinite

Similar function which checks input for NaNs and Infs.

fromiter

Create an array from an iterator.

fromfunction

Construct an array by executing a function on grid positions.

Examples

Convert a list into an array:

```
>>> a = [1, 2]
>>> import numpy as np
>>> np.asanyarray(a)
array([1, 2])
```

Instances of `ndarray` subclasses are passed through as-is:

```
>>> a = np.array([(1., 2), (3., 4)], dtype='f4,i4').view(np.recarray)
>>> np.asanyarray(a) is a
True
```

`numpy.ascontiguousarray(a, dtype=None, *, like=None)`

Return a contiguous array (`ndim >= 1`) in memory (C order).

Parameters

a

[array_like] Input array.

dtype

[str or dtype object, optional] Data-type of returned array.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[ndarray] Contiguous array of same shape and content as *a*, with type *dtype* if specified.

See also:

[`asfortranarray`](#)

Convert input to an ndarray with column-major memory order.

[`require`](#)

Return an ndarray that satisfies requirements.

[`ndarray.flags`](#)

Information about the memory layout of the array.

Examples

Starting with a Fortran-contiguous array:

```
>>> import numpy as np
>>> x = np.ones((2, 3), order='F')
>>> x.flags['F_CONTIGUOUS']
True
```

Calling `ascontiguousarray` makes a C-contiguous copy:

```
>>> y = np.ascontiguousarray(x)
>>> y.flags['C_CONTIGUOUS']
True
>>> np.may_share_memory(x, y)
False
```

Now, starting with a C-contiguous array:

```
>>> x = np.ones((2, 3), order='C')
>>> x.flags['C_CONTIGUOUS']
True
```

Then, calling `ascontiguousarray` returns the same object:

```
>>> y = np.ascontiguousarray(x)
>>> x is y
True
```

Note: This function returns an array with at least one-dimension (1-d) so it will not preserve 0-d arrays.

`numpy.astype(x, dtype, /, *, copy=True, device=None)`

Copies an array to a specified data type.

This function is an Array API compatible alternative to `numpy.ndarray.astype`.

Parameters

x
[ndarray] Input NumPy array to cast. `array_likes` are explicitly not supported here.

dtype
[dtype] Data type of the result.

copy
[bool, optional] Specifies whether to copy an array when the specified dtype matches the data type of the input array `x`. If `True`, a newly allocated array must always be returned. If `False` and the specified dtype matches the data type of the input array, the input array must be returned; otherwise, a newly allocated array must be returned. Defaults to `True`.

device
[str, optional] The device on which to place the returned array. Default: `None`. For Array-API interoperability only, so must be `"cpu"` if passed.
New in version 2.1.0.

Returns

out
[ndarray] An array having the specified data type.

See also:

[`ndarray.astype`](#)

Examples

```
>>> import numpy as np
>>> arr = np.array([1, 2, 3]); arr
array([1, 2, 3])
>>> np.astype(arr, np.float64)
array([1., 2., 3.])
```

Non-copy case:

```
>>> arr = np.array([1, 2, 3])
>>> arr_noncopy = np.astype(arr, arr.dtype, copy=False)
>>> np.shares_memory(arr, arr_noncopy)
True
```

`numpy.copy(a, order='K', subok=False)`

Return an array copy of the given object.

Parameters

a

[array_like] Input data.

order

[['C', 'F', 'A', 'K'], optional] Controls the memory layout of the copy. 'C' means C-order, 'F' means F-order, 'A' means 'F' if *a* is Fortran contiguous, 'C' otherwise. 'K' means match the layout of *a* as closely as possible. (Note that this function and [`ndarray.copy`](#) are very similar, but have different default values for their `order=` arguments.)

subok

[bool, optional] If True, then sub-classes will be passed-through, otherwise the returned array will be forced to be a base-class array (defaults to False).

Returns

arr

[ndarray] Array interpretation of *a*.

See also:

[`ndarray.copy`](#)

Preferred method for creating an array copy

Notes

This is equivalent to:

```
>>> np.array(a, copy=True)
```

The copy made of the data is shallow, i.e., for arrays with object dtype, the new array will point to the same objects. See Examples from [ndarray.copy](#).

Examples

```
>>> import numpy as np
```

Create an array x, with a reference y and a copy z:

```
>>> x = np.array([1, 2, 3])
>>> y = x
>>> z = np.copy(x)
```

Note that, when we modify x, y changes, but not z:

```
>>> x[0] = 10
>>> x[0] == y[0]
True
>>> x[0] == z[0]
False
```

Note that, `np.copy` clears previously set `WRITEABLE=False` flag.

```
>>> a = np.array([1, 2, 3])
>>> a.flags["WRITEABLE"] = False
>>> b = np.copy(a)
>>> b.flags["WRITEABLE"]
True
>>> b[0] = 3
>>> b
array([3, 2, 3])
```

`numpy.frombuffer` (*buffer*, *dtype=np.float64*, *count=-1*, *offset=0*, *, *like=None*)

Interpret a buffer as a 1-dimensional array.

Parameters

buffer

[*buffer_like*] An object that exposes the buffer interface.

dtype

[*data-type*, optional] Data-type of the returned array. Default is `numpy.float64`.

count

[*int*, optional] Number of items to read. `-1` means all data in the buffer.

offset

[*int*, optional] Start reading the buffer from this offset (in bytes); default: 0.

like

[*array_like*, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol,

the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out
[ndarray]

See also:

`ndarray.tobytes`

Inverse of this operation, construct Python bytes from the raw data bytes in the array.

Notes

If the buffer has data that is not in machine byte-order, this should be specified as part of the data-type, e.g.:

```
>>> dt = np.dtype(np.int_)
>>> dt = dt.newbyteorder('>')
>>> np.frombuffer(buf, dtype=dt)
```

The data of the resulting array will not be byteswapped, but will be interpreted correctly.

This function creates a view into the original object. This should be safe in general, but it may make sense to copy the result when the original object is mutable or untrusted.

Examples

```
>>> import numpy as np
>>> s = b'hello world'
>>> np.frombuffer(s, dtype='S1', count=5, offset=6)
array([b'w', b'o', b'r', b'l', b'd'], dtype='|S1')
```

```
>>> np.frombuffer(b'\x01\x02', dtype=np.uint8)
array([1, 2], dtype=uint8)
>>> np.frombuffer(b'\x01\x02\x03\x04\x05', dtype=np.uint8, count=3)
array([1, 2, 3], dtype=uint8)
```

`numpy.from_dlpack` (*x*, */*, *, *device=None*, *copy=None*)

Create a NumPy array from an object implementing the `__dlpack__` protocol. Generally, the returned NumPy array is a view of the input object. See [1] and [2] for more details.

Parameters

x
[object] A Python object that implements the `__dlpack__` and `__dlpack_device__` methods.

device
[device, optional] Device on which to place the created array. Default: `None`. Must be `"cpu"` if passed which may allow importing an array that is not already CPU available.

copy
[bool, optional] Boolean indicating whether or not to copy the input. If `True`, the copy will be made. If `False`, the function will never copy, and will raise `BufferError` in case

a copy is deemed necessary. Passing it requests a copy from the exporter who may or may not implement the capability. If `None`, the function will reuse the existing memory buffer if possible and copy otherwise. Default: `None`.

Returns

out

[ndarray]

References

[1], [2]

Examples

```
>>> import torch
>>> x = torch.arange(10)
>>> # create a view of the torch tensor "x" in NumPy
>>> y = np.from_dlpack(x)
```

`numpy.fromfile` (*file*, *dtype=np.float64*, *count=-1*, *sep="*, *offset=0*, ***, *like=None*)

Construct an array from data in a text or binary file.

A highly efficient way of reading binary data with a known data-type, as well as parsing simply formatted text files. Data written using the *tofile* method can be read using this function.

Parameters

file

[file or str or Path] An open file object, a string containing the filename, or a Path object. When reading from a file object it must support random access (i.e. it must have tell and seek methods).

dtype

[data-type] Data type of the returned array. For binary files, it is used to determine the size and byte-order of the items in the file. Most builtin numeric types are supported and extension types may be supported.

count

[int] Number of items to read. `-1` means all items (i.e., the complete file).

sep

[str] Separator between items if file is a text file. Empty ("") separator means the file should be treated as binary. Spaces (" ") in the separator match zero or more whitespace characters. A separator consisting only of spaces must match at least one whitespace.

offset

[int] The offset (in bytes) from the file's current position. Defaults to 0. Only permitted for binary files.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

See also:

`load`, `save`
`ndarray.tofile`
`loadtxt`

More flexible way of loading data from a text file.

Notes

Do not rely on the combination of `tofile` and `fromfile` for data storage, as the binary files generated are not platform independent. In particular, no byte-order or data-type information is saved. Data can be stored in the platform independent `.npy` format using `save` and `load` instead.

Examples

Construct an ndarray:

```
>>> import numpy as np
>>> dt = np.dtype([('time', [('min', np.int64), ('sec', np.int64)]),
...               ('temp', float)])
>>> x = np.zeros((1,), dtype=dt)
>>> x['time']['min'] = 10; x['temp'] = 98.25
>>> x
array([(10, 0), 98.25]),
      dtype=[('time', [('min', '<i8'), ('sec', '<i8')]), ('temp', '<f8')])
```

Save the raw data to disk:

```
>>> import tempfile
>>> fname = tempfile.mkstemp()[1]
>>> x.tofile(fname)
```

Read the raw data from disk:

```
>>> np.fromfile(fname, dtype=dt)
array([(10, 0), 98.25]),
      dtype=[('time', [('min', '<i8'), ('sec', '<i8')]), ('temp', '<f8')])
```

The recommended way to store and load data:

```
>>> np.save(fname, x)
>>> np.load(fname + '.npy')
array([(10, 0), 98.25]),
      dtype=[('time', [('min', '<i8'), ('sec', '<i8')]), ('temp', '<f8')])
```

`numpy.fromfunction` (*function*, *shape*, *, *dtype*=<class 'float'>, *like*=None, ***kwargs*)

Construct an array by executing a function over each coordinate.

The resulting array therefore has a value $fn(x, y, z)$ at coordinate (x, y, z) .

Parameters

function

[callable] The function is called with N parameters, where N is the rank of `shape`. Each parameter represents the coordinates of the array varying along a specific axis. For example,

if *shape* were (2, 2), then the parameters would be `array([[0, 0], [1, 1]])` and `array([[0, 1], [0, 1]])`

shape

[*N*,] tuple of ints] Shape of the output array, which also determines the shape of the coordinate arrays passed to *function*.

dtype

[data-type, optional] Data-type of the coordinate arrays passed to *function*. By default, *dtype* is float.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns**fromfunction**

[any] The result of the call to *function* is passed back directly. Therefore the shape of *fromfunction* is completely determined by *function*. If *function* returns a scalar value, the shape of *fromfunction* would not match the *shape* parameter.

See also:

indices, meshgrid

Notes

Keywords other than *dtype* and *like* are passed to *function*.

Examples

```
>>> import numpy as np
>>> np.fromfunction(lambda i, j: i, (2, 2), dtype=np.float64)
array([[0., 0.],
       [1., 1.]])
```

```
>>> np.fromfunction(lambda i, j: j, (2, 2), dtype=np.float64)
array([[0., 1.],
       [0., 1.]])
```

```
>>> np.fromfunction(lambda i, j: i == j, (3, 3), dtype=np.int_)
array([[ True, False, False],
       [False,  True, False],
       [False, False,  True]])
```

```
>>> np.fromfunction(lambda i, j: i + j, (3, 3), dtype=np.int_)
array([[0, 1, 2],
       [1, 2, 3],
       [2, 3, 4]])
```

`numpy.fromiter(iter, dtype, count=-1, *, like=None)`

Create a new 1-dimensional array from an iterable object.

Parameters

iter

[iterable object] An iterable object providing data for the array.

dtype

[data-type] The data-type of the returned array.

Changed in version 1.23: Object and subarray dtypes are now supported (note that the final result is not 1-D for a subarray dtype).

count

[int, optional] The number of items to read from *iterable*. The default is -1, which means all data is read.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[ndarray] The output array.

Notes

Specify *count* to improve performance. It allows `fromiter` to pre-allocate the output array, instead of resizing it on demand.

Examples

```
>>> import numpy as np
>>> iterable = (x*x for x in range(5))
>>> np.fromiter(iterable, float)
array([ 0.,  1.,  4.,  9., 16.]
```

A carefully constructed subarray dtype will lead to higher dimensional results:

```
>>> iterable = ((x+1, x+2) for x in range(5))
>>> np.fromiter(iterable, dtype=np.dtype((int, 2)))
array([[1, 2],
       [2, 3],
       [3, 4],
       [4, 5],
       [5, 6]])
```

`numpy.fromstring(string, dtype=np.float64, count=-1, *, sep, like=None)`

A new 1-D array initialized from text data in a string.

Parameters

string

[str] A string containing the data.

dtype

[data-type, optional] The data type of the array; default: `numpy.float64`. For binary input data, the data must be in exactly this format. Most builtin numeric types are supported and extension types may be supported.

count

[int, optional] Read this number of `dtype` elements from the data. If this is negative (the default), the count will be determined from the length of the data.

sep

[str, optional] The string separating numbers in the data; extra whitespace between elements is also ignored.

Deprecated since version 1.14: Passing `sep=' '`, the default, is deprecated since it will trigger the deprecated binary mode of this function. This mode interprets `string` as binary bytes, rather than ASCII text with decimal numbers, an operation which is better spelt `frombuffer(string, dtype, count)`. If `string` contains unicode text, the binary mode of `fromstring` will first encode it into bytes using utf-8, which will not produce sane results.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns**arr**

[ndarray] The constructed array.

Raises**ValueError**

If the string is not the correct size to satisfy the requested `dtype` and `count`.

See also:

`frombuffer`, `fromfile`, `fromiter`

Examples

```
>>> import numpy as np
>>> np.fromstring('1 2', dtype=np.int_, sep=' ')
array([1, 2])
>>> np.fromstring('1, 2', dtype=np.int_, sep=',')
array([1, 2])
```

`numpy.loadtxt` (*fname*, *dtype*=<class 'float'>, *comments*='#', *delimiter*=None, *converters*=None, *skiprows*=0, *usecols*=None, *unpack*=False, *ndmin*=0, *encoding*=None, *max_rows*=None, *, *quotechar*=None, *like*=None)

Load data from a text file.

Parameters

fname

[file, str, pathlib.Path, list of str, generator] File, filename, list, or generator to read. If the filename extension is `.gz` or `.bz2`, the file is first decompressed. Note that generators must return bytes or strings. The strings in a list or produced by a generator are treated as lines.

dtype

[data-type, optional] Data-type of the resulting array; default: float. If this is a structured data-type, the resulting array will be 1-dimensional, and each row will be interpreted as an element of the array. In this case, the number of columns used must match the number of fields in the data-type.

comments

[str or sequence of str or None, optional] The characters or list of characters used to indicate the start of a comment. None implies no comments. For backwards compatibility, byte strings will be decoded as 'latin1'. The default is '#'.

delimiter

[str, optional] The character used to separate the values. For backwards compatibility, byte strings will be decoded as 'latin1'. The default is whitespace.

Changed in version 1.23.0: Only single character delimiters are supported. Newline characters cannot be used as the delimiter.

converters

[dict or callable, optional] Converter functions to customize value parsing. If *converters* is callable, the function is applied to all columns, else it must be a dict that maps column number to a parser function. See examples for further details. Default: None.

Changed in version 1.23.0: The ability to pass a single callable to be applied to all columns was added.

skiprows

[int, optional] Skip the first *skiprows* lines, including comments; default: 0.

usecols

[int or sequence, optional] Which columns to read, with 0 being the first. For example, `usecols = (1, 4, 5)` will extract the 2nd, 5th and 6th columns. The default, None, results in all columns being read.

unpack

[bool, optional] If True, the returned array is transposed, so that arguments may be unpacked using `x, y, z = loadtxt(...)`. When used with a structured data-type, arrays are returned for each field. Default is False.

ndmin

[int, optional] The returned array will have at least *ndmin* dimensions. Otherwise mono-dimensional axes will be squeezed. Legal values: 0 (default), 1 or 2.

encoding

[str, optional] Encoding used to decode the inputfile. Does not apply to input streams. The special value 'bytes' enables backward compatibility workarounds that ensures you receive byte arrays as results if possible and passes 'latin1' encoded strings to converters. Override this value to receive unicode arrays and pass strings as input to converters. If set to None the system default is used. The default value is None.

Changed in version 2.0: Before NumPy 2, the default was 'bytes' for Python 2 compatibility. The default is now None.

max_rows

[int, optional] Read *max_rows* rows of content after *skiprows* lines. The default is to read all

the rows. Note that empty rows containing no data such as empty lines and comment lines are not counted towards *max_rows*, while such lines are counted in *skiprows*.

Changed in version 1.23.0: Lines containing no data, including comment lines (e.g., lines starting with '#' or as specified via *comments*) are not counted towards *max_rows*.

quotechar

[unicode character or None, optional] The character used to denote the start and end of a quoted item. Occurrences of the delimiter or comment characters are ignored within a quoted item. The default value is `quotechar=None`, which means quoting support is disabled.

If two consecutive instances of *quotechar* are found within a quoted field, the first is treated as an escape character. See examples.

New in version 1.23.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns**out**

[ndarray] Data read from the text file.

See also:

load, *fromstring*, *fromregex*
genfromtxt

Load data with missing values handled as specified.

scipy.io.loadmat
reads MATLAB data files

Notes

This function aims to be a fast reader for simply formatted files. The *genfromtxt* function provides more sophisticated handling of, e.g., lines with missing values.

Each row in the input text file must have the same number of values to be able to read all values. If all rows do not have same number of values, a subset of up to *n* columns (where *n* is the least number of values present in all rows) can be read by specifying the columns via *usecols*.

The strings produced by the Python `float.hex` method can be used as input for floats.

Examples

```
>>> import numpy as np
>>> from io import StringIO # StringIO behaves like a file object
>>> c = StringIO("0 1\n2 3")
>>> np.loadtxt(c)
array([[0., 1.],
       [2., 3.]])
```

```
>>> d = StringIO("M 21 72\nF 35 58")
>>> np.loadtxt(d, dtype={'names': ('gender', 'age', 'weight'),
...                             'formats': ('S1', 'i4', 'f4')})
array([(b'M', 21, 72.), (b'F', 35, 58.)],
      dtype=[('gender', 'S1'), ('age', '<i4'), ('weight', '<f4')])
```

```
>>> c = StringIO("1,0,2\n3,0,4")
>>> x, y = np.loadtxt(c, delimiter=',', usecols=(0, 2), unpack=True)
>>> x
array([1., 3.])
>>> y
array([2., 4.])
```

The *converters* argument is used to specify functions to preprocess the text prior to parsing. *converters* can be a dictionary that maps preprocessing functions to each column:

```
>>> s = StringIO("1.618, 2.296\n3.141, 4.669\n")
>>> conv = {
...     0: lambda x: np.floor(float(x)), # conversion fn for column 0
...     1: lambda x: np.ceil(float(x)), # conversion fn for column 1
... }
>>> np.loadtxt(s, delimiter=",", converters=conv)
array([[1., 3.],
       [3., 5.]])
```

converters can be a callable instead of a dictionary, in which case it is applied to all columns:

```
>>> s = StringIO("0xDE 0xAD\n0xC0 0xDE")
>>> import functools
>>> conv = functools.partial(int, base=16)
>>> np.loadtxt(s, converters=conv)
array([[222., 173.],
       [192., 222.]])
```

This example shows how *converters* can be used to convert a field with a trailing minus sign into a negative number.

```
>>> s = StringIO("10.01 31.25-\n19.22 64.31\n17.57- 63.94")
>>> def conv(fld):
...     return -float(fld[:-1]) if fld.endswith("-") else float(fld)
...
>>> np.loadtxt(s, converters=conv)
array([[ 10.01, -31.25],
       [ 19.22,  64.31],
       [-17.57,  63.94]])
```

Using a callable as the converter can be particularly useful for handling values with different formatting, e.g. floats with underscores:

```
>>> s = StringIO("1 2.7 100_000")
>>> np.loadtxt(s, converters=float)
array([1.e+00, 2.7e+00, 1.e+05])
```

This idea can be extended to automatically handle values specified in many different formats, such as hex values:

```
>>> def conv(val):
...     try:
...         return float(val)
...     except ValueError:
...         return float.fromhex(val)
>>> s = StringIO("1, 2.5, 3_000, 0b4, 0x1.4000000000000p+2")
>>> np.loadtxt(s, delimiter=",", converters=conv)
array([1.0e+00, 2.5e+00, 3.0e+03, 1.8e+02, 5.0e+00])
```

Or a format where the `-` sign comes after the number:

```
>>> s = StringIO("10.01 31.25-\n19.22 64.31\n17.57- 63.94")
>>> conv = lambda x: -float(x[:-1]) if x.endswith("-") else float(x)
>>> np.loadtxt(s, converters=conv)
array([[ 10.01, -31.25],
       [ 19.22,  64.31],
       [-17.57,  63.94]])
```

Support for quoted fields is enabled with the *quotechar* parameter. Comment and delimiter characters are ignored when they appear within a quoted item delineated by *quotechar*:

```
>>> s = StringIO('"alpha, #42", 10.0\n"beta, #64", 2.0\n')
>>> dtype = np.dtype([("label", "U12"), ("value", float)])
>>> np.loadtxt(s, dtype=dtype, delimiter=",", quotechar='"')
array([('alpha, #42', 10.), ('beta, #64', 2.)],
      dtype=[('label', '<U12'), ('value', '<f8')])
```

Quoted fields can be separated by multiple whitespace characters:

```
>>> s = StringIO('"alpha, #42"      10.0\n"beta, #64" 2.0\n')
>>> dtype = np.dtype([("label", "U12"), ("value", float)])
>>> np.loadtxt(s, dtype=dtype, delimiter=None, quotechar='"')
array([('alpha, #42', 10.), ('beta, #64', 2.)],
      dtype=[('label', '<U12'), ('value', '<f8')])
```

Two consecutive quote characters within a quoted field are treated as a single escaped character:

```
>>> s = StringIO('"Hello, my name is "Monty"! "')
>>> np.loadtxt(s, dtype=np.str_, delimiter=",", quotechar='"')
array('Hello, my name is "Monty"!', dtype='<U26')
```

Read subset of columns when all rows do not contain equal number of values:

```
>>> d = StringIO("1 2\n2 4\n3 9 12\n4 16 20")
>>> np.loadtxt(d, usecols=(0, 1))
array([[ 1.,  2.],
       [ 2.,  4.],
       [ 3.,  9.],
       [ 4., 16.]])
```

Creating record arrays

Note: Please refer to [Record arrays](#) for record arrays.

<code>rec.array(obj[, dtype, shape, offset, ...])</code>	Construct a record array from a wide-variety of objects.
<code>rec.fromarrays(arrayList[, dtype, shape, ...])</code>	Create a record array from a (flat) list of arrays
<code>rec.fromrecords(recList[, dtype, shape, ...])</code>	Create a recarray from a list of records in text form.
<code>rec.fromstring(datastring[, dtype, shape, ...])</code>	Create a record array from binary data
<code>rec.fromfile(fd[, dtype, shape, offset, ...])</code>	Create an array from binary file data

Creating character arrays (`numpy.char`)

Note: `numpy.char` is used to create character arrays.

<code>char.array(obj[, itemsize, copy, unicode, order])</code>	Create a chararray .
<code>char.asarray(obj[, itemsize, unicode, order])</code>	Convert the input to a chararray , copying the data only if necessary.

Numerical ranges

<code>arange([start,]stop[, step,][, dtype, ...])</code>	Return evenly spaced values within a given interval.
<code>linspace(start, stop[, num, endpoint, ...])</code>	Return evenly spaced numbers over a specified interval.
<code>logspace(start, stop[, num, endpoint, base, ...])</code>	Return numbers spaced evenly on a log scale.
<code>geomspace(start, stop[, num, endpoint, ...])</code>	Return numbers spaced evenly on a log scale (a geometric progression).
<code>meshgrid(*xi[, copy, sparse, indexing])</code>	Return a tuple of coordinate matrices from coordinate vectors.
<code>mgrid</code>	An instance which returns a dense multi-dimensional "meshgrid".
<code>ogrid</code>	An instance which returns an open multi-dimensional "meshgrid".

`numpy.arange` (`[start, ]stop, [step, ]dtype=None, *, device=None, like=None`)

Return evenly spaced values within a given interval.

`arange` can be called with a varying number of positional arguments:

- `arange(stop)`: Values are generated within the half-open interval `[0, stop)` (in other words, the interval including `start` but excluding `stop`).
- `arange(start, stop)`: Values are generated within the half-open interval `[start, stop)`.
- `arange(start, stop, step)`: Values are generated within the half-open interval `[start, stop)`, with spacing between values given by `step`.

For integer arguments the function is roughly equivalent to the Python built-in `range`, but returns an `ndarray` rather than a `range` instance.

When using a non-integer step, such as 0.1, it is often better to use `numpy.linspace`.

See the Warning sections below for more information.

Parameters

start

[integer or real, optional] Start of interval. The interval includes this value. The default start value is 0.

stop

[integer or real] End of interval. The interval does not include this value, except in some cases where *step* is not an integer and floating point round-off affects the length of *out*.

step

[integer or real, optional] Spacing between values. For any output *out*, this is the distance between two adjacent values, `out[i+1] - out[i]`. The default step size is 1. If *step* is specified as a position argument, *start* must also be given.

dtype

[dtype, optional] The type of the output array. If *dtype* is not given, infer the data type from the other input arguments.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

arange

[ndarray] Array of evenly spaced values.

For floating point arguments, the length of the result is `ceil((stop - start)/step)`. Because of floating point overflow, this rule may result in the last element of *out* being greater than *stop*.

Warning: The length of the output might not be numerically stable.

Another stability issue is due to the internal implementation of `numpy.arange`. The actual step value used to populate the array is `dtype(start + step) - dtype(start)` and not *step*. Precision loss can occur here, due to casting or due to using floating points when *start* is much larger than *step*. This can lead to unexpected behaviour. For example:

```
>>> np.arange(0, 5, 0.5, dtype=np.int_)
array([0, 0, 0, 0, 0, 0, 0, 0, 0, 0])
>>> np.arange(-3, 3, 0.5, dtype=np.int_)
array([-3, -2, -1,  0,  1,  2,  3,  4,  5,  6,  7,  8])
```

In such cases, the use of `numpy.linspace` should be preferred.

The built-in `range` generates Python built-in integers that have arbitrary size, while `numpy.arange` produces `numpy.int32` or `numpy.int64` numbers. This may result in incorrect results for large integer values:

```
>>> power = 40
>>> modulo = 10000
>>> x1 = [(n ** power) % modulo for n in range(8)]
>>> x2 = [(n ** power) % modulo for n in np.arange(8)]
>>> print(x1)
[0, 1, 7776, 8801, 6176, 625, 6576, 4001] # correct
>>> print(x2)
[0, 1, 7776, 7185, 0, 5969, 4816, 3361] # incorrect
```

See also:

`numpy.linspace`

Evenly spaced numbers with careful handling of endpoints.

`numpy.ogrid`

Arrays of evenly spaced numbers in N-dimensions.

`numpy.mgrid`

Grid-shaped arrays of evenly spaced numbers in N-dimensions.

how-to-partition

Examples

```
>>> import numpy as np
>>> np.arange(3)
array([0, 1, 2])
>>> np.arange(3.0)
array([ 0.,  1.,  2.])
>>> np.arange(3,7)
array([3, 4, 5, 6])
>>> np.arange(3,7,2)
array([3, 5])
```

`numpy.linspace` (*start*, *stop*, *num*=50, *endpoint*=True, *retstep*=False, *dtype*=None, *axis*=0, *, *device*=None)

Return evenly spaced numbers over a specified interval.

Returns *num* evenly spaced samples, calculated over the interval [*start*, *stop*].

The endpoint of the interval can optionally be excluded.

Changed in version 1.20.0: Values are rounded towards $-\infty$ instead of 0 when an integer dtype is specified. The old behavior can still be obtained with `np.linspace(start, stop, num).astype(np.int_)`

Parameters

start

[array_like] The starting value of the sequence.

stop

[array_like] The end value of the sequence, unless *endpoint* is set to False. In that case, the sequence consists of all but the last of *num* + 1 evenly spaced samples, so that *stop* is excluded. Note that the step size changes when *endpoint* is False.

num

[int, optional] Number of samples to generate. Default is 50. Must be non-negative.

endpoint

[bool, optional] If True, *stop* is the last sample. Otherwise, it is not included. Default is True.

retstep

[bool, optional] If True, return (*samples*, *step*), where *step* is the spacing between samples.

dtype

[dtype, optional] The type of the output array. If *dtype* is not given, the data type is inferred from *start* and *stop*. The inferred dtype will never be an integer; *float* is chosen even if the arguments would produce an array of integers.

axis

[int, optional] The axis in the result to store the samples. Relevant only if *start* or *stop* are array-like. By default (0), the samples will be along a new axis inserted at the beginning. Use -1 to get an axis at the end.

device

[str, optional] The device on which to place the created array. Default: None. For Array-API interoperability only, so must be "cpu" if passed.

New in version 2.0.0.

Returns**samples**

[ndarray] There are *num* equally spaced samples in the closed interval [*start*, *stop*] or the half-open interval [*start*, *stop*) (depending on whether *endpoint* is True or False).

step

[float, optional] Only returned if *retstep* is True

Size of spacing between samples.

See also:***arange***

Similar to *linspace*, but uses a step size (instead of the number of samples).

geomspace

Similar to *linspace*, but with numbers spaced evenly on a log scale (a geometric progression).

logspace

Similar to *geomspace*, but with the end points specified as logarithms.

how-to-partition**Examples**

```
>>> import numpy as np
>>> np.linspace(2.0, 3.0, num=5)
array([2. , 2.25, 2.5 , 2.75, 3.  ])
>>> np.linspace(2.0, 3.0, num=5, endpoint=False)
array([2. , 2.2, 2.4, 2.6, 2.8])
>>> np.linspace(2.0, 3.0, num=5, retstep=True)
(array([2. , 2.25, 2.5 , 2.75, 3.  ]), 0.25)
```

Graphical illustration:

```

>>> import matplotlib.pyplot as plt
>>> N = 8
>>> y = np.zeros(N)
>>> x1 = np.linspace(0, 10, N, endpoint=True)
>>> x2 = np.linspace(0, 10, N, endpoint=False)
>>> plt.plot(x1, y, 'o')
[<matplotlib.lines.Line2D object at 0x...>]
>>> plt.plot(x2, y + 0.5, 'o')
[<matplotlib.lines.Line2D object at 0x...>]
>>> plt.ylim([-0.5, 1])
(-0.5, 1)
>>> plt.show()

```

`numpy.linspace` (*start*, *stop*, *num*=50, *endpoint*=True, *base*=10.0, *dtype*=None, *axis*=0)

Return numbers spaced evenly on a log scale.

In linear space, the sequence starts at `base ** start` (*base* to the power of *start*) and ends with `base ** stop` (see *endpoint* below).

Changed in version 1.25.0: Non-scalar 'base' is now supported

Parameters

start

[array_like] `base ** start` is the starting value of the sequence.

stop

[array_like] `base ** stop` is the final value of the sequence, unless *endpoint* is False. In that case, `num + 1` values are spaced over the interval in log-space, of which all but the last (a sequence of length *num*) are returned.

num

[integer, optional] Number of samples to generate. Default is 50.

endpoint

[boolean, optional] If true, *stop* is the last sample. Otherwise, it is not included. Default is True.

base

[array_like, optional] The base of the log space. The step size between the elements in $\ln(\text{samples}) / \ln(\text{base})$ (or `log_base(samples)`) is uniform. Default is 10.0.

dtype

[dtype] The type of the output array. If *dtype* is not given, the data type is inferred from *start* and *stop*. The inferred type will never be an integer; *float* is chosen even if the arguments would produce an array of integers.

axis

[int, optional] The axis in the result to store the samples. Relevant only if *start*, *stop*, or *base* are array-like. By default (0), the samples will be along a new axis inserted at the beginning. Use -1 to get an axis at the end.

Returns**samples**

[ndarray] *num* samples, equally spaced on a log scale.

See also:*arange*

Similar to `linspace`, with the step size specified instead of the number of samples. Note that, when used with a float endpoint, the endpoint may or may not be included.

linspace

Similar to `logspace`, but with the samples uniformly distributed in linear space, instead of log space.

geomspace

Similar to `logspace`, but with endpoints specified directly.

how-to-partition**Notes**

If *base* is a scalar, `logspace` is equivalent to the code

```
>>> y = np.linspace(start, stop, num=num, endpoint=endpoint)
...
>>> power(base, y).astype(dtype)
...
```

Examples

```
>>> import numpy as np
>>> np.logspace(2.0, 3.0, num=4)
array([ 100.          ,  215.443469   ,  464.15888336, 1000.          ])
>>> np.logspace(2.0, 3.0, num=4, endpoint=False)
array([100.          ,  177.827941   ,  316.22776602,  562.34132519])
>>> np.logspace(2.0, 3.0, num=4, base=2.0)
array([4.          ,  5.0396842   ,  6.34960421,  8.          ])
>>> np.logspace(2.0, 3.0, num=4, base=[2.0, 3.0], axis=-1)
array([[ 4.          ,  5.0396842   ,  6.34960421,  8.          ],
       [ 9.          , 12.98024613, 18.72075441, 27.          ]])
```

Graphical illustration:

```

>>> import matplotlib.pyplot as plt
>>> N = 10
>>> x1 = np.logspace(0.1, 1, N, endpoint=True)
>>> x2 = np.logspace(0.1, 1, N, endpoint=False)
>>> y = np.zeros(N)
>>> plt.plot(x1, y, 'o')
[<matplotlib.lines.Line2D object at 0x...>]
>>> plt.plot(x2, y + 0.5, 'o')
[<matplotlib.lines.Line2D object at 0x...>]
>>> plt.ylim([-0.5, 1])
(-0.5, 1)
>>> plt.show()

```

`numpy.geomspace` (*start*, *stop*, *num*=50, *endpoint*=True, *dtype*=None, *axis*=0)

Return numbers spaced evenly on a log scale (a geometric progression).

This is similar to [logspace](#), but with endpoints specified directly. Each output sample is a constant multiple of the previous.

Parameters

start

[array_like] The starting value of the sequence.

stop

[array_like] The final value of the sequence, unless *endpoint* is False. In that case, *num* + 1 values are spaced over the interval in log-space, of which all but the last (a sequence of length *num*) are returned.

num

[integer, optional] Number of samples to generate. Default is 50.

endpoint

[boolean, optional] If true, *stop* is the last sample. Otherwise, it is not included. Default is True.

dtype

[dtype] The type of the output array. If *dtype* is not given, the data type is inferred from *start*

and *stop*. The inferred dtype will never be an integer; *float* is chosen even if the arguments would produce an array of integers.

axis

[int, optional] The axis in the result to store the samples. Relevant only if start or stop are array-like. By default (0), the samples will be along a new axis inserted at the beginning. Use -1 to get an axis at the end.

Returns**samples**

[ndarray] *num* samples, equally spaced on a log scale.

See also:

logspace

Similar to *geomspace*, but with endpoints specified using log and base.

linspace

Similar to *geomspace*, but with arithmetic instead of geometric progression.

arange

Similar to *linspace*, with the step size specified instead of the number of samples.

how-to-partition**Notes**

If the inputs or dtype are complex, the output will follow a logarithmic spiral in the complex plane. (There are an infinite number of spirals passing through two points; the output will follow the shortest such path.)

Examples

```
>>> import numpy as np
>>> np.geomspace(1, 1000, num=4)
array([ 1., 10., 100., 1000.])
>>> np.geomspace(1, 1000, num=3, endpoint=False)
array([ 1., 10., 100.])
>>> np.geomspace(1, 1000, num=4, endpoint=False)
array([ 1., 5.62341325, 31.6227766, 177.827941])
>>> np.geomspace(1, 256, num=9)
array([ 1., 2., 4., 8., 16., 32., 64., 128., 256.])
```

Note that the above may not produce exact integers:

```
>>> np.geomspace(1, 256, num=9, dtype=np.int_)
array([ 1, 2, 4, 7, 16, 32, 63, 127, 256])
>>> np.around(np.geomspace(1, 256, num=9)).astype(np.int_)
array([ 1, 2, 4, 8, 16, 32, 64, 128, 256])
```

Negative, decreasing, and complex inputs are allowed:

```
>>> np.geomspace(1000, 1, num=4)
array([1000., 100., 10., 1.])
>>> np.geomspace(-1000, -1, num=4)
array([-1000., -100., -10., -1.])
>>> np.geomspace(1j, 1000j, num=4) # Straight line
```

(continues on next page)

(continued from previous page)

```
array([0.   +1.j, 0.  +10.j, 0. +100.j, 0.+1000.j])
>>> np.geomspace(-1+0j, 1+0j, num=5) # Circle
array([-1.00000000e+00+1.22464680e-16j, -7.07106781e-01+7.07106781e-01j,
        6.12323400e-17+1.00000000e+00j,  7.07106781e-01+7.07106781e-01j,
        1.00000000e+00+0.00000000e+00j])
```

Graphical illustration of *endpoint* parameter:

```
>>> import matplotlib.pyplot as plt
>>> N = 10
>>> y = np.zeros(N)
>>> plt.semilogx(np.geomspace(1, 1000, N, endpoint=True), y + 1, 'o')
[<matplotlib.lines.Line2D object at 0x...>]
>>> plt.semilogx(np.geomspace(1, 1000, N, endpoint=False), y + 2, 'o')
[<matplotlib.lines.Line2D object at 0x...>]
>>> plt.axis([0.5, 2000, 0, 3])
[0.5, 2000, 0, 3]
>>> plt.grid(True, color='0.7', linestyle='-', which='both', axis='both')
>>> plt.show()
```

`numpy.meshgrid(*xi, copy=True, sparse=False, indexing='xy')`

Return a tuple of coordinate matrices from coordinate vectors.

Make N-D coordinate arrays for vectorized evaluations of N-D scalar/vector fields over N-D grids, given one-dimensional coordinate arrays $x_1, x_2, \dots, x_n$.

Parameters

$x_1, x_2, \dots, x_n$

[array_like] 1-D arrays representing the coordinates of a grid.

indexing

[{'xy', 'ij'}, optional] Cartesian ('xy', default) or matrix ('ij') indexing of output. See Notes for more details.

sparse

[bool, optional] If True the shape of the returned coordinate array for dimension i is reduced

from $(N_1, \dots, N_i, \dots, N_n)$ to $(1, \dots, 1, N_i, 1, \dots, 1)$. These sparse coordinate grids are intended to be used with `basics.broadcasting`. When all coordinates are used in an expression, broadcasting still leads to a fully-dimensional result array.

Default is `False`.

copy

[bool, optional] If `False`, a view into the original arrays are returned in order to conserve memory. Default is `True`. Please note that `sparse=False, copy=False` will likely return non-contiguous arrays. Furthermore, more than one element of a broadcast array may refer to a single memory location. If you need to write to the arrays, make copies first.

Returns

X1, X2,..., XN

[tuple of ndarrays] For vectors $x_1, x_2, \dots, x_n$ with lengths $N_i = \text{len}(x_i)$, returns $(N_1, N_2, N_3, \dots, N_n)$ shaped arrays if `indexing='ij'` or $(N_2, N_1, N_3, \dots, N_n)$ shaped arrays if `indexing='xy'` with the elements of x_i repeated to fill the matrix along the first dimension for x_1 , the second for x_2 and so on.

See also:

mggrid

Construct a multi-dimensional “meshgrid” using indexing notation.

ogrid

Construct an open multi-dimensional “meshgrid” using indexing notation.

how-to-index

Notes

This function supports both indexing conventions through the `indexing` keyword argument. Giving the string `'ij'` returns a meshgrid with matrix indexing, while `'xy'` returns a meshgrid with Cartesian indexing. In the 2-D case with inputs of length M and N , the outputs are of shape (N, M) for `'xy'` indexing and (M, N) for `'ij'` indexing. In the 3-D case with inputs of length M, N and P , outputs are of shape (N, M, P) for `'xy'` indexing and (M, N, P) for `'ij'` indexing. The difference is illustrated by the following code snippet:

```
xv, yv = np.meshgrid(x, y, indexing='ij')
for i in range(nx):
    for j in range(ny):
        # treat xv[i,j], yv[i,j]

xv, yv = np.meshgrid(x, y, indexing='xy')
for i in range(nx):
    for j in range(ny):
        # treat xv[j,i], yv[j,i]
```

In the 1-D and 0-D case, the `indexing` and `sparse` keywords have no effect.

Examples

```
>>> import numpy as np
>>> nx, ny = (3, 2)
>>> x = np.linspace(0, 1, nx)
>>> y = np.linspace(0, 1, ny)
>>> xv, yv = np.meshgrid(x, y)
>>> xv
array([[0. , 0.5, 1. ],
       [0. , 0.5, 1. ]])
>>> yv
array([[0., 0., 0.],
       [1., 1., 1.]])
```

The result of `meshgrid` is a coordinate grid:

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(xv, yv, marker='o', color='k', linestyle='none')
>>> plt.show()
```

You can create sparse output arrays to save memory and computation time.

```
>>> xv, yv = np.meshgrid(x, y, sparse=True)
>>> xv
array([[0. , 0.5, 1. ]])
>>> yv
array([[0.],
       [1.]])
```

`meshgrid` is very useful to evaluate functions on a grid. If the function depends on all coordinates, both dense and sparse outputs can be used.

```
>>> x = np.linspace(-5, 5, 101)
>>> y = np.linspace(-5, 5, 101)
>>> # full coordinate arrays
>>> xx, yy = np.meshgrid(x, y)
```

(continues on next page)

(continued from previous page)

```

>>> zz = np.sqrt(xx**2 + yy**2)
>>> xx.shape, yy.shape, zz.shape
((101, 101), (101, 101), (101, 101))
>>> # sparse coordinate arrays
>>> xs, ys = np.meshgrid(x, y, sparse=True)
>>> zs = np.sqrt(xs**2 + ys**2)
>>> xs.shape, ys.shape, zs.shape
((1, 101), (101, 1), (101, 101))
>>> np.array_equal(zz, zs)
True

```

```

>>> h = plt.contourf(x, y, zs)
>>> plt.axis('scaled')
>>> plt.colorbar()
>>> plt.show()

```

`numpy.mgrid` = `<numpy.lib._index_tricks_impl.MGridClass object>`

An instance which returns a dense multi-dimensional “meshgrid”.

An instance which returns a dense (or fleshed out) mesh-grid when indexed, so that each returned argument has the same shape. The dimensions and number of the output arrays are equal to the number of indexing dimensions. If the step length is not a complex number, then the stop is not inclusive.

However, if the step length is a **complex number** (e.g. 5j), then the integer part of its magnitude is interpreted as specifying the number of points to create between the start and stop values, where the stop value **is inclusive**.

Returns

`mesh-grid`

[ndarray] A single array, containing a set of `ndarrays` all of the same dimensions, stacked along the first axis.

See also:

`ogrid`

like `mgrid` but returns open (not fleshed out) mesh grids

meshgrid

return coordinate matrices from coordinate vectors

r_

array concatenator

how-to-partition**Examples**

```
>>> import numpy as np
>>> np.mgrid[0:5, 0:5]
array([[0, 0, 0, 0, 0],
       [1, 1, 1, 1, 1],
       [2, 2, 2, 2, 2],
       [3, 3, 3, 3, 3],
       [4, 4, 4, 4, 4]],
      [[0, 1, 2, 3, 4],
       [0, 1, 2, 3, 4],
       [0, 1, 2, 3, 4],
       [0, 1, 2, 3, 4],
       [0, 1, 2, 3, 4]])
>>> np.mgrid[-1:1:5j]
array([-1. , -0.5,  0. ,  0.5,  1. ])
```

```
>>> np.mgrid[0:4].shape
(4,)
>>> np.mgrid[0:4, 0:5].shape
(2, 4, 5)
>>> np.mgrid[0:4, 0:5, 0:6].shape
(3, 4, 5, 6)
```

`numpy.ogrid = <numpy.lib._index_tricks_impl.OMeshClass object>`

An instance which returns an open multi-dimensional “meshgrid”.

An instance which returns an open (i.e. not fleshed out) mesh-grid when indexed, so that only one dimension of each returned array is greater than 1. The dimension and number of the output arrays are equal to the number of indexing dimensions. If the step length is not a complex number, then the stop is not inclusive.

However, if the step length is a **complex number** (e.g. 5j), then the integer part of its magnitude is interpreted as specifying the number of points to create between the start and stop values, where the stop value **is inclusive**.

Returns**mesh-grid**

[ndarray or tuple of ndarrays] If the input is a single slice, returns an array. If the input is multiple slices, returns a tuple of arrays, with only one dimension not equal to 1.

See also:**mgrid**

like *ogrid* but returns dense (or fleshed out) mesh grids

meshgrid

return coordinate matrices from coordinate vectors

r_

array concatenator

how-to-partition

Examples

```
>>> from numpy import ogrid
>>> ogrid[-1:1:5j]
array([-1. , -0.5,  0. ,  0.5,  1. ])
>>> ogrid[0:5, 0:5]
(array([[0],
        [1],
        [2],
        [3],
        [4]]),
 array([[0, 1, 2, 3, 4]]))
```

Building matrices

<code>diag(v[, k])</code>	Extract a diagonal or construct a diagonal array.
<code>diagflat(v[, k])</code>	Create a two-dimensional array with the flattened input as a diagonal.
<code>tri(N[, M, k, dtype, like])</code>	An array with ones at and below the given diagonal and zeros elsewhere.
<code>tril(m[, k])</code>	Lower triangle of an array.
<code>triu(m[, k])</code>	Upper triangle of an array.
<code>vander(x[, N, increasing])</code>	Generate a Vandermonde matrix.

`numpy.diag(v, k=0)`

Extract a diagonal or construct a diagonal array.

See the more detailed documentation for `numpy.diagonal` if you use this function to extract a diagonal and wish to write to the resulting array; whether it returns a copy or a view depends on what version of numpy you are using.

Parameters

v

[array_like] If *v* is a 2-D array, return a copy of its *k*-th diagonal. If *v* is a 1-D array, return a 2-D array with *v* on the *k*-th diagonal.

k

[int, optional] Diagonal in question. The default is 0. Use *k*>0 for diagonals above the main diagonal, and *k*<0 for diagonals below the main diagonal.

Returns

out

[ndarray] The extracted diagonal or constructed diagonal array.

See also:

[`diagonal`](#)

Return specified diagonals.

[`diagflat`](#)

Create a 2-D array with the flattened input as a diagonal.

trace

Sum along diagonals.

triu

Upper triangle of an array.

tril

Lower triangle of an array.

Examples

```
>>> import numpy as np
>>> x = np.arange(9).reshape((3,3))
>>> x
array([[0, 1, 2],
       [3, 4, 5],
       [6, 7, 8]])
```

```
>>> np.diag(x)
array([0, 4, 8])
>>> np.diag(x, k=1)
array([1, 5])
>>> np.diag(x, k=-1)
array([3, 7])
```

```
>>> np.diag(np.diag(x))
array([[0, 0, 0],
       [0, 4, 0],
       [0, 0, 8]])
```

`numpy.diagflat(v, k=0)`

Create a two-dimensional array with the flattened input as a diagonal.

Parameters**v**[array_like] Input data, which is flattened and set as the k -th diagonal of the output.**k**[int, optional] Diagonal to set; 0, the default, corresponds to the “main” diagonal, a positive (negative) k giving the number of the diagonal above (below) the main.**Returns****out**

[ndarray] The 2-D output array.

See also:**diag**

MATLAB work-alike for 1-D and 2-D arrays.

diagonal

Return specified diagonals.

trace

Sum along diagonals.

Examples

```
>>> import numpy as np
>>> np.diagflat([[1,2], [3,4]])
array([[1, 0, 0, 0],
       [0, 2, 0, 0],
       [0, 0, 3, 0],
       [0, 0, 0, 4]])
```

```
>>> np.diagflat([1,2], 1)
array([[0, 1, 0],
       [0, 0, 2],
       [0, 0, 0]])
```

`numpy.tri(N, M=None, k=0, dtype=<class 'float'>, *, like=None)`

An array with ones at and below the given diagonal and zeros elsewhere.

Parameters

N

[int] Number of rows in the array.

M

[int, optional] Number of columns in the array. By default, *M* is taken equal to *N*.

k

[int, optional] The sub-diagonal at and below which the array is filled. *k* = 0 is the main diagonal, while *k* < 0 is below it, and *k* > 0 is above. The default is 0.

dtype

[dtype, optional] Data type of the returned array. The default is float.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

tri

[ndarray of shape (N, M)] Array with its lower triangle filled with ones and zero elsewhere; in other words $T[i, j] == 1$ for $j \leq i + k$, 0 otherwise.

Examples

```
>>> import numpy as np
>>> np.tri(3, 5, 2, dtype=np.int_)
array([[1, 1, 1, 0, 0],
       [1, 1, 1, 1, 0],
       [1, 1, 1, 1, 1]])
```

```
>>> np.tri(3, 5, -1)
array([[0., 0., 0., 0., 0.],
       [1., 0., 0., 0., 0.],
       [1., 1., 0., 0., 0.]])
```

(continues on next page)

(continued from previous page)

```
[1., 0., 0., 0., 0.],
[1., 1., 0., 0., 0.]])
```

`numpy.tril(m, k=0)`

Lower triangle of an array.

Return a copy of an array with elements above the k -th diagonal zeroed. For arrays with `ndim` exceeding 2, `tril` will apply to the final two axes.

Parameters

m

[array_like, shape (... , M, N)] Input array.

k

[int, optional] Diagonal above which to zero elements. $k = 0$ (the default) is the main diagonal, $k < 0$ is below it and $k > 0$ is above.

Returns

tril

[ndarray, shape (... , M, N)] Lower triangle of *m*, of same shape and data-type as *m*.

See also:

`triu`

same thing, only for the upper triangle

Examples

```
>>> import numpy as np
>>> np.tril([[1,2,3],[4,5,6],[7,8,9],[10,11,12]], -1)
array([[ 0,  0,  0],
       [ 4,  0,  0],
       [ 7,  8,  0],
       [10, 11, 12]])
```

```
>>> np.tril(np.arange(3*4*5).reshape(3, 4, 5))
array([[[ 0,  0,  0,  0,  0],
        [ 5,  6,  0,  0,  0],
        [10, 11, 12,  0,  0],
        [15, 16, 17, 18,  0]],
       [[20,  0,  0,  0,  0],
        [25, 26,  0,  0,  0],
        [30, 31, 32,  0,  0],
        [35, 36, 37, 38,  0]],
       [[40,  0,  0,  0,  0],
        [45, 46,  0,  0,  0],
        [50, 51, 52,  0,  0],
        [55, 56, 57, 58,  0]]])
```

`numpy.triu(m, k=0)`

Upper triangle of an array.

Return a copy of an array with the elements below the k -th diagonal zeroed. For arrays with `ndim` exceeding 2, `triu` will apply to the final two axes.

Please refer to the documentation for `tril` for further details.

See also:

`tril`

lower triangle of an array

Examples

```
>>> import numpy as np
>>> np.triu([[1,2,3],[4,5,6],[7,8,9],[10,11,12]], -1)
array([[ 1,  2,  3],
       [ 4,  5,  6],
       [ 0,  8,  9],
       [ 0,  0, 12]])
```

```
>>> np.triu(np.arange(3*4*5).reshape(3, 4, 5))
array([[[ 0,  1,  2,  3,  4],
       [ 0,  6,  7,  8,  9],
       [ 0,  0, 12, 13, 14],
       [ 0,  0,  0, 18, 19]],
      [[20, 21, 22, 23, 24],
       [ 0, 26, 27, 28, 29],
       [ 0,  0, 32, 33, 34],
       [ 0,  0,  0, 38, 39]],
      [[40, 41, 42, 43, 44],
       [ 0, 46, 47, 48, 49],
       [ 0,  0, 52, 53, 54],
       [ 0,  0,  0, 58, 59]]])
```

`numpy.vander` (*x*, *N=None*, *increasing=False*)

Generate a Vandermonde matrix.

The columns of the output matrix are powers of the input vector. The order of the powers is determined by the *increasing* boolean argument. Specifically, when *increasing* is False, the *i*-th output column is the input vector raised element-wise to the power of $N - i - 1$. Such a matrix with a geometric progression in each row is named for Alexandre- Theophile Vandermonde.

Parameters

x

[array_like] 1-D input array.

N

[int, optional] Number of columns in the output. If *N* is not specified, a square array is returned ($N = \text{len}(x)$).

increasing

[bool, optional] Order of the powers of the columns. If True, the powers increase from left to right, if False (the default) they are reversed.

Returns

out

[ndarray] Vandermonde matrix. If *increasing* is False, the first column is $x^{(N-1)}$, the second $x^{(N-2)}$ and so forth. If *increasing* is True, the columns are x^0 , x^1 , ..., $x^{(N-1)}$.

See also:

polynomial.polynomial.polyvander

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 3, 5])
>>> N = 3
>>> np.vander(x, N)
array([[ 1,  1,  1],
       [ 4,  2,  1],
       [ 9,  3,  1],
       [25,  5,  1]])
```

```
>>> np.column_stack([x**(N-1-i) for i in range(N)])
array([[ 1,  1,  1],
       [ 4,  2,  1],
       [ 9,  3,  1],
       [25,  5,  1]])
```

```
>>> x = np.array([1, 2, 3, 5])
>>> np.vander(x)
array([[ 1,  1,  1,  1],
       [ 8,  4,  2,  1],
       [27,  9,  3,  1],
       [125, 25,  5,  1]])
>>> np.vander(x, increasing=True)
array([[ 1,  1,  1,  1],
       [ 1,  2,  4,  8],
       [ 1,  3,  9, 27],
       [ 1,  5, 25, 125]])
```

The determinant of a square Vandermonde matrix is the product of the differences between the values of the input vector:

```
>>> np.linalg.det(np.vander(x))
48.0000000000000043 # may vary
>>> (5-3)*(5-2)*(5-1)*(3-2)*(3-1)*(2-1)
48
```

The matrix class

bmat(obj[, ldict, gdict])

Build a matrix object from a string, nested sequence, or array.

1.4.3 Array manipulation routines

Basic operations

<code>copyto(dst, src[, casting, where])</code>	Copies values from one array to another, broadcasting as necessary.
<code>ndim(a)</code>	Return the number of dimensions of an array.
<code>shape(a)</code>	Return the shape of an array.
<code>size(a[, axis])</code>	Return the number of elements along a given axis.

`numpy.copyto(dst, src, casting='same_kind', where=True)`

Copies values from one array to another, broadcasting as necessary.

Raises a `TypeError` if the *casting* rule is violated, and if *where* is provided, it selects which elements to copy.

Parameters

dst

[ndarray] The array into which values are copied.

src

[array_like] The array from which values are copied.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur when copying.

- 'no' means the data types should not be cast at all.
- 'equiv' means only byte-order changes are allowed.
- 'safe' means only casts which can preserve values are allowed.
- 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed.
- 'unsafe' means any data conversions may be done.

where

[array_like of bool, optional] A boolean array which is broadcasted to match the dimensions of *dst*, and selects elements to copy from *src* to *dst* wherever it contains the value `True`.

Examples

```
>>> import numpy as np
>>> A = np.array([4, 5, 6])
>>> B = [1, 2, 3]
>>> np.copyto(A, B)
>>> A
array([1, 2, 3])
```

```
>>> A = np.array([[1, 2, 3], [4, 5, 6]])
>>> B = [[4, 5, 6], [7, 8, 9]]
>>> np.copyto(A, B)
>>> A
array([[4, 5, 6],
       [7, 8, 9]])
```

`numpy.ndim(a)`

Return the number of dimensions of an array.

Parameters

a

[array_like] Input array. If it is not already an ndarray, a conversion is attempted.

Returns

number_of_dimensions

[int] The number of dimensions in *a*. Scalars are zero-dimensional.

See also:

[`ndarray.ndim`](#)

equivalent method

[`shape`](#)

dimensions of array

[`ndarray.shape`](#)

dimensions of array

Examples

```
>>> import numpy as np
>>> np.ndim([[1,2,3],[4,5,6]])
2
>>> np.ndim(np.array([[1,2,3],[4,5,6]]))
2
>>> np.ndim(1)
0
```

`numpy.shape(a)`

Return the shape of an array.

Parameters

a

[array_like] Input array.

Returns

shape

[tuple of ints] The elements of the shape tuple give the lengths of the corresponding array dimensions.

See also:

[`len`](#)

`len(a)` is equivalent to `np.shape(a)[0]` for N-D arrays with $N \geq 1$.

[`ndarray.shape`](#)

Equivalent array method.

Examples

```
>>> import numpy as np
>>> np.shape(np.eye(3))
(3, 3)
>>> np.shape([[1, 3]])
(1, 2)
>>> np.shape([0])
(1,)
>>> np.shape(0)
()
```

```
>>> a = np.array([(1, 2), (3, 4), (5, 6)],
...              dtype=[('x', 'i4'), ('y', 'i4')])
>>> np.shape(a)
(3,)
>>> a.shape
(3,)
```

`numpy.size(a, axis=None)`

Return the number of elements along a given axis.

Parameters

a

[array_like] Input data.

axis

[None or int or tuple of ints, optional] Axis or axes along which the elements are counted. By default, give the total number of elements.

Changed in version 2.4: Extended to accept multiple axes.

Returns

element_count

[int] Number of elements along the specified axis.

See also:

[*shape*](#)

dimensions of array

[*ndarray.shape*](#)

dimensions of array

[*ndarray.size*](#)

number of elements in array

Examples

```
>>> import numpy as np
>>> a = np.array([[1,2,3],[4,5,6]])
>>> np.size(a)
6
>>> np.size(a,axis=1)
3
>>> np.size(a,axis=0)
2
>>> np.size(a,axis=(0,1))
6
```

Changing array shape

<code>reshape(a, /, shape[, order, copy])</code>	Returns a reshaped ndarray without changing data.
<code>ravel(a[, order])</code>	Return a contiguous flattened array.
<code>ndarray.flat</code>	A 1-D iterator over the array.
<code>ndarray.flatten([order])</code>	Return a copy of the array collapsed into one dimension.

`numpy.reshape(a, /, shape, order='C', *, copy=None)`

Returns a reshaped ndarray without changing data.

Parameters

a

[array_like] Array to be reshaped.

shape

[int or tuple of ints] The new shape should be compatible with the original shape. If an integer, then the result will be a 1-D array of that length. One shape dimension can be -1. In this case, the value is inferred from the length of the array and remaining dimensions.

order

[{'C', 'F', 'A'}, optional] Read the elements of *a* using this index order, and place the elements into the reshaped array using this index order. 'C' means to read / write the elements using C-like index order, with the last axis index changing fastest, back to the first axis index changing slowest. 'F' means to read / write the elements using Fortran-like index order, with the first index changing fastest, and the last index changing slowest. Note that the 'C' and 'F' options take no account of the memory layout of the underlying array, and only refer to the order of indexing. 'A' means to read / write the elements in Fortran-like index order if *a* is Fortran *contiguous* in memory, C-like order otherwise.

copy

[bool, optional] If True, then the array data is copied. If None, a copy will only be made if it's required by *order*. For False it raises a `ValueError` if a copy cannot be avoided. Default: None.

Returns

reshaped_array

[ndarray] This will be a new view object if possible; otherwise, it will be a copy. Note there is no guarantee of the *memory layout* (C- or Fortran- contiguous) of the returned array.

See also:

`ndarray.reshape`

Equivalent method.

Notes

It is not always possible to change the shape of an array without copying the data.

The `order` keyword gives the index ordering both for *fetching* the values from `a`, and then *placing* the values into the output array. For example, let's say you have an array:

```
>>> a = np.arange(6).reshape((3, 2))
>>> a
array([[0, 1],
       [2, 3],
       [4, 5]])
```

You can think of reshaping as first raveling the array (using the given index order), then inserting the elements from the raveled array into the new array using the same kind of index ordering as was used for the raveling.

```
>>> np.reshape(a, (2, 3)) # C-like index ordering
array([[0, 1, 2],
       [3, 4, 5]])
>>> np.reshape(np.ravel(a), (2, 3)) # equivalent to C ravel then C reshape
array([[0, 1, 2],
       [3, 4, 5]])
>>> np.reshape(a, (2, 3), order='F') # Fortran-like index ordering
array([[0, 4, 3],
       [2, 1, 5]])
>>> np.reshape(np.ravel(a, order='F'), (2, 3), order='F')
array([[0, 4, 3],
       [2, 1, 5]])
```

Examples

```
>>> import numpy as np
>>> a = np.array([[1,2,3], [4,5,6]])
>>> np.reshape(a, 6)
array([1, 2, 3, 4, 5, 6])
>>> np.reshape(a, 6, order='F')
array([1, 4, 2, 5, 3, 6])
```

```
>>> np.reshape(a, (3,-1)) # the unspecified value is inferred to be 2
array([[1, 2],
       [3, 4],
       [5, 6]])
```

`numpy.ravel(a, order='C')`

Return a contiguous flattened array.

A 1-D array, containing the elements of the input, is returned. A copy is made only if needed.

As of NumPy 1.10, the returned array will have the same type as the input array. (for example, a masked array will be returned for a masked array input)

Parameters

a
[array_like] Input array. The elements in *a* are read in the order specified by *order*, and packed as a 1-D array.

order
[{'C','F', 'A', 'K'}, optional] The elements of *a* are read using this index order. 'C' means to index the elements in row-major, C-style order, with the last axis index changing fastest, back to the first axis index changing slowest. 'F' means to index the elements in column-major, Fortran-style order, with the first index changing fastest, and the last index changing slowest. Note that the 'C' and 'F' options take no account of the memory layout of the underlying array, and only refer to the order of axis indexing. 'A' means to read the elements in Fortran-like index order if *a* is Fortran *contiguous* in memory, C-like order otherwise. 'K' means to read the elements in the order they occur in memory, except for reversing the data when strides are negative. By default, 'C' index order is used.

Returns

y
[array_like] *y* is a contiguous 1-D array of the same subtype as *a*, with shape `(a.size,)`. Note that matrices are special cased for backward compatibility, if *a* is a matrix, then *y* is a 1-D ndarray.

See also:

[`ndarray.flat`](#)

1-D iterator over an array.

[`ndarray.flatten`](#)

1-D array copy of the elements of an array in row-major order.

[`ndarray.reshape`](#)

Change the shape of an array without changing its data.

Notes

In row-major, C-style order, in two dimensions, the row index varies the slowest, and the column index the quickest. This can be generalized to multiple dimensions, where row-major order implies that the index along the first axis varies slowest, and the index along the last quickest. The opposite holds for column-major, Fortran-style index ordering.

When a view is desired in as many cases as possible, `arr.reshape(-1)` may be preferable. However, `ravel` supports *K* in the optional *order* argument while `reshape` does not.

Examples

It is equivalent to `reshape(-1, order=order)`.

```
>>> import numpy as np
>>> x = np.array([[1, 2, 3], [4, 5, 6]])
>>> np.ravel(x)
array([1, 2, 3, 4, 5, 6])
```

```
>>> x.reshape(-1)
array([1, 2, 3, 4, 5, 6])
```

```
>>> np.ravel(x, order='F')
array([1, 4, 2, 5, 3, 6])
```

When order is 'A', it will preserve the array's 'C' or 'F' ordering:

```
>>> np.ravel(x.T)
array([1, 4, 2, 5, 3, 6])
>>> np.ravel(x.T, order='A')
array([1, 2, 3, 4, 5, 6])
```

When order is 'K', it will preserve orderings that are neither 'C' nor 'F', but won't reverse axes:

```
>>> a = np.arange(3)[::-1]; a
array([2, 1, 0])
>>> a.ravel(order='C')
array([2, 1, 0])
>>> a.ravel(order='K')
array([2, 1, 0])
```

```
>>> a = np.arange(12).reshape(2,3,2).swapaxes(1,2); a
array([[[ 0,  2,  4],
        [ 1,  3,  5]],
       [[ 6,  8, 10],
        [ 7,  9, 11]]])
>>> a.ravel(order='C')
array([ 0,  2,  4,  1,  3,  5,  6,  8, 10,  7,  9, 11])
>>> a.ravel(order='K')
array([ 0,  1,  2,  3,  4,  5,  6,  7,  8,  9, 10, 11])
```

Transpose-like operations

<code>moveaxis(a, source, destination)</code>	Move axes of an array to new positions.
<code>rollaxis(a, axis[, start])</code>	Roll the specified axis backwards, until it lies in a given position.
<code>swapaxes(a, axis1, axis2)</code>	Interchange two axes of an array.
<code>ndarray.T</code>	View of the transposed array.
<code>transpose(a[, axes])</code>	Returns an array with axes transposed.
<code>permute_dims(a[, axes])</code>	Returns an array with axes transposed.
<code>matrix_transpose(x, /)</code>	Transposes a matrix (or a stack of matrices) <i>x</i> .

`numpy.moveaxis(a, source, destination)`

Move axes of an array to new positions.

Other axes remain in their original order.

Parameters

a

[np.ndarray] The array whose axes should be reordered.

source

[int or sequence of int] Original positions of the axes to move. These must be unique.

destination

[int or sequence of int] Destination positions for each of the original axes. These must also be unique.

Returns**result**

[np.ndarray] Array with moved axes. This array is a view of the input array.

See also:

transpose

Permute the dimensions of an array.

swapaxes

Interchange two axes of an array.

Examples

```
>>> import numpy as np
>>> x = np.zeros((3, 4, 5))
>>> np.moveaxis(x, 0, -1).shape
(4, 5, 3)
>>> np.moveaxis(x, -1, 0).shape
(5, 3, 4)
```

These all achieve the same result:

```
>>> np.transpose(x).shape
(5, 4, 3)
>>> np.swapaxes(x, 0, -1).shape
(5, 4, 3)
>>> np.moveaxis(x, [0, 1], [-1, -2]).shape
(5, 4, 3)
>>> np.moveaxis(x, [0, 1, 2], [-1, -2, -3]).shape
(5, 4, 3)
```

numpy.**rollaxis** (*a*, *axis*, *start*=0)

Roll the specified axis backwards, until it lies in a given position.

This function continues to be supported for backward compatibility, but you should prefer *moveaxis*. The *moveaxis* function was added in NumPy 1.11.

Parameters**a**

[ndarray] Input array.

axis

[int] The axis to be rolled. The positions of the other axes do not change relative to one another.

start

[int, optional] When *start* ≤ *axis*, the axis is rolled back until it lies in this position. When *start* > *axis*, the axis is rolled until it lies before this position. The default, 0, results in a “complete” roll. The following table describes how negative values of *start* are interpreted:

start	Normalized start
<code>-(arr.ndim+1)</code>	<code>raise AxisError</code>
<code>-arr.ndim</code>	<code>0</code>
<code>:</code>	<code>:</code>
<code>-1</code>	<code>arr.ndim-1</code>
<code>0</code>	<code>0</code>
<code>:</code>	<code>:</code>
<code>arr.ndim</code>	<code>arr.ndim</code>
<code>arr.ndim + 1</code>	<code>raise AxisError</code>

Returns

res

[ndarray] For NumPy $\geq$ 1.10.0 a view of *a* is always returned. For earlier NumPy versions a view of *a* is returned only if the order of the axes is changed, otherwise the input array is returned.

See also:

[*moveaxis*](#)

Move array axes to new positions.

[*roll*](#)

Roll the elements of an array by a number of positions along a given axis.

Examples

```
>>> import numpy as np
>>> a = np.ones((3,4,5,6))
>>> np.rollaxis(a, 3, 1).shape
(3, 6, 4, 5)
>>> np.rollaxis(a, 2).shape
(5, 3, 4, 6)
>>> np.rollaxis(a, 1, 4).shape
(3, 5, 6, 4)
```

`numpy.swapaxes(a, axis1, axis2)`

Interchange two axes of an array.

Parameters

a

[array_like] Input array.

axis1

[int] First axis.

axis2

[int] Second axis.

Returns

a_swapped

[ndarray] For NumPy $\geq$ 1.10.0, if *a* is an ndarray, then a view of *a* is returned; otherwise a new array is created. For earlier NumPy versions a view of *a* is returned only if the order of the axes is changed, otherwise the input array is returned.

Examples

```
>>> import numpy as np
>>> x = np.array([[1, 2, 3]])
>>> np.swapaxes(x, 0, 1)
array([[1],
       [2],
       [3]])
```

```
>>> x = np.array([[0, 1], [2, 3]], [[4, 5], [6, 7]])
>>> x
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7]])
```

```
>>> np.swapaxes(x, 0, 2)
array([[0, 4],
       [2, 6],
       [1, 5],
       [3, 7]])
```

`numpy.transpose(a, axes=None)`

Returns an array with axes transposed.

For a 1-D array, this returns an unchanged view of the original array, as a transposed vector is simply the same vector. To convert a 1-D array into a 2-D column vector, an additional dimension must be added, e.g., `np.atleast_2d(a).T` achieves this, as does `a[:, np.newaxis]`. For a 2-D array, this is the standard matrix transpose. For an n-D array, if axes are given, their order indicates how the axes are permuted (see Examples). If axes are not provided, then `transpose(a).shape == a.shape[::-1]`.

Parameters

a
[array_like] Input array.

axes
[tuple or list of ints, optional] If specified, it must be a tuple or list which contains a permutation of [0, 1, ..., N-1] where N is the number of axes of *a*. Negative indices can also be used to specify axes. The *i*-th axis of the returned array will correspond to the axis numbered `axes[i]` of the input. If not specified, defaults to `range(a.ndim)[::-1]`, which reverses the order of the axes.

Returns

p
[ndarray] *a* with its axes permuted. A view is returned whenever possible.

See also:

[`ndarray.transpose`](#)

Equivalent method.

[`moveaxis`](#)

Move axes of an array to new positions.

[`argsort`](#)

Return the indices that would sort an array.

Notes

Use `transpose(a, argsort(axes))` to invert the transposition of tensors when using the *axes* keyword argument.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> a
array([[1, 2],
       [3, 4]])
>>> np.transpose(a)
array([[1, 3],
       [2, 4]])
```

```
>>> a = np.array([1, 2, 3, 4])
>>> a
array([1, 2, 3, 4])
>>> np.transpose(a)
array([1, 2, 3, 4])
```

```
>>> a = np.ones((1, 2, 3))
>>> np.transpose(a, (1, 0, 2)).shape
(2, 1, 3)
```

```
>>> a = np.ones((2, 3, 4, 5))
>>> np.transpose(a).shape
(5, 4, 3, 2)
```

```
>>> a = np.arange(3*4*5).reshape((3, 4, 5))
>>> np.transpose(a, (-1, 0, -2)).shape
(5, 3, 4)
```

`numpy.permute_dims(a, axes=None)`

Returns an array with axes transposed.

For a 1-D array, this returns an unchanged view of the original array, as a transposed vector is simply the same vector. To convert a 1-D array into a 2-D column vector, an additional dimension must be added, e.g., `np.atleast_2d(a).T` achieves this, as does `a[:, np.newaxis]`. For a 2-D array, this is the standard matrix transpose. For an n-D array, if axes are given, their order indicates how the axes are permuted (see Examples). If axes are not provided, then `transpose(a).shape == a.shape[::-1]`.

Parameters

a
[array_like] Input array.

axes
[tuple or list of ints, optional] If specified, it must be a tuple or list which contains a permutation of `[0, 1, ..., N-1]` where `N` is the number of axes of *a*. Negative indices can also be used to specify axes. The *i*-th axis of the returned array will correspond to the axis numbered `axes[i]` of the input. If not specified, defaults to `range(a.ndim)[::-1]`, which reverses the order of the axes.

Returns

p[ndarray] *a* with its axes permuted. A view is returned whenever possible.**See also:*****ndarray.transpose***

Equivalent method.

moveaxis

Move axes of an array to new positions.

argsort

Return the indices that would sort an array.

Notes

Use `transpose(a, argsort(axes))` to invert the transposition of tensors when using the *axes* keyword argument.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> a
array([[1, 2],
       [3, 4]])
>>> np.transpose(a)
array([[1, 3],
       [2, 4]])
```

```
>>> a = np.array([1, 2, 3, 4])
>>> a
array([1, 2, 3, 4])
>>> np.transpose(a)
array([1, 2, 3, 4])
```

```
>>> a = np.ones((1, 2, 3))
>>> np.transpose(a, (1, 0, 2)).shape
(2, 1, 3)
```

```
>>> a = np.ones((2, 3, 4, 5))
>>> np.transpose(a).shape
(5, 4, 3, 2)
```

```
>>> a = np.arange(3*4*5).reshape((3, 4, 5))
>>> np.transpose(a, (-1, 0, -2)).shape
(5, 3, 4)
```

`numpy.matrix_transpose(x, /)`

Transposes a matrix (or a stack of matrices) *x*.

This function is Array API compatible.

Parameters

x

[array_like] Input array having shape $(\dots, M, N)$ and whose two innermost dimensions form $M \times N$ matrices.

Returns**out**

[ndarray] An array containing the transpose for each matrix and having shape $(\dots, N, M)$.

See also:*transpose*

Generic transpose method.

Examples

```
>>> import numpy as np
>>> np.matrix_transpose([[1, 2], [3, 4]])
array([[1, 3],
       [2, 4]])
```

```
>>> np.matrix_transpose([[[1, 2], [3, 4]], [[5, 6], [7, 8]]])
array([[[1, 3],
       [2, 4]],
       [[5, 7],
       [6, 8]]])
```

Changing number of dimensions

<i>atleast_1d</i> (*arys)	Convert inputs to arrays with at least one dimension.
<i>atleast_2d</i> (*arys)	View inputs as arrays with at least two dimensions.
<i>atleast_3d</i> (*arys)	View inputs as arrays with at least three dimensions.
<i>broadcast</i> (*arrays)	Produce an object that mimics broadcasting.
<i>broadcast_to</i> (array, shape[, subok])	Broadcast an array to a new shape.
<i>broadcast_arrays</i> (*args[, subok])	Broadcast any number of arrays against each other.
<i>expand_dims</i> (a, axis)	Expand the shape of an array.
<i>squeeze</i> (a[, axis])	Remove axes of length one from <i>a</i> .

`numpy.atleast_1d` (*arys)

Convert inputs to arrays with at least one dimension.

Scalar inputs are converted to 1-dimensional arrays, whilst higher-dimensional inputs are preserved.

Parameters**arys1, arys2, ...**

[array_like] One or more input arrays.

Returns**ret**

[ndarray] An array, or tuple of arrays, each with `a.ndim >= 1`. Copies are made only if necessary.

See also:

atleast_2d, atleast_3d

Examples

```
>>> import numpy as np
>>> np.atleast_1d(1.0)
array([1.])
```

```
>>> x = np.arange(9.0).reshape(3,3)
>>> np.atleast_1d(x)
array([[0., 1., 2.],
       [3., 4., 5.],
       [6., 7., 8.]])
>>> np.atleast_1d(x) is x
True
```

```
>>> np.atleast_1d(1, [3, 4])
(array([1]), array([3, 4]))
```

`numpy.atleast_2d(*arys)`

View inputs as arrays with at least two dimensions.

Parameters

arys1, arys2, ...

[array_like] One or more array-like sequences. Non-array inputs are converted to arrays. Arrays that already have two or more dimensions are preserved.

Returns

res, res2, ...

[ndarray] An array, or tuple of arrays, each with `a.ndim >= 2`. Copies are avoided where possible, and views with two or more dimensions are returned.

See also:

atleast_1d, atleast_3d

Examples

```
>>> import numpy as np
>>> np.atleast_2d(3.0)
array([[3.]])
```

```
>>> x = np.arange(3.0)
>>> np.atleast_2d(x)
array([[0., 1., 2.]])
>>> np.atleast_2d(x).base is x
True
```

```
>>> np.atleast_2d(1, [1, 2], [[1, 2]])
(array([[1]]), array([[1, 2]]), array([[1, 2]]))
```

`numpy.atleast_3d(*arys)`

View inputs as arrays with at least three dimensions.

Parameters

arys1, arys2, ...

[array_like] One or more array-like sequences. Non-array inputs are converted to arrays. Arrays that already have three or more dimensions are preserved.

Returns

res1, res2, ...

[ndarray] An array, or tuple of arrays, each with `a.ndim >= 3`. Copies are avoided where possible, and views with three or more dimensions are returned. For example, a 1-D array of shape `(N,)` becomes a view of shape `(1, N, 1)`, and a 2-D array of shape `(M, N)` becomes a view of shape `(M, N, 1)`.

See also:

[`atleast\_1d`](#), [`atleast\_2d`](#)

Examples

```
>>> import numpy as np
>>> np.atleast_3d(3.0)
array([[[3.]])
```

```
>>> x = np.arange(3.0)
>>> np.atleast_3d(x).shape
(1, 3, 1)
```

```
>>> x = np.arange(12.0).reshape(4,3)
>>> np.atleast_3d(x).shape
(4, 3, 1)
>>> np.atleast_3d(x).base is x.base # x is a reshape, so not base itself
True
```

```
>>> for arr in np.atleast_3d([1, 2], [[1, 2]], [[[1, 2]]]):
...     print(arr, arr.shape)
...
[[[1]
 [2]]] (1, 2, 1)
[[[1]
 [2]]] (1, 2, 1)
[[[1 2]]] (1, 1, 2)
```

`numpy.broadcast_to(array, shape, subok=False)`

Broadcast an array to a new shape.

Parameters

array

[array_like] The array to broadcast.

shape

[tuple or int] The shape of the desired array. A single integer `i` is interpreted as `(i,)`.

subok

[bool, optional] If True, then sub-classes will be passed-through, otherwise the returned array will be forced to be a base-class array (default).

Returns**broadcast**

[array] A readonly view on the original array with the given shape. It is typically not contiguous. Furthermore, more than one element of a broadcasted array may refer to a single memory location.

Raises**ValueError**

If the array is not compatible with the new shape according to NumPy's broadcasting rules.

See also:

[broadcast](#)

[broadcast_arrays](#)

[broadcast_shapes](#)

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 3])
>>> np.broadcast_to(x, (3, 3))
array([[1, 2, 3],
       [1, 2, 3],
       [1, 2, 3]])
```

`numpy.broadcast_arrays(*args, subok=False)`

Broadcast any number of arrays against each other.

Parameters***args**

[array_likes] The arrays to broadcast.

subok

[bool, optional] If True, then sub-classes will be passed-through, otherwise the returned arrays will be forced to be a base-class array (default).

Returns**broadcasted**

[tuple of arrays] These arrays are views on the original arrays. They are typically not contiguous. Furthermore, more than one element of a broadcasted array may refer to a single memory location. If you need to write to the arrays, make copies first. While you can set the `writable` flag True, writing to a single output value may end up changing more than one location in the output array.

Deprecated since version 1.17: The output is currently marked so that if written to, a deprecation warning will be emitted. A future version will set the `writable` flag False so writing to it will raise an error.

See also:

broadcast
broadcast_to
broadcast_shapes

Examples

```
>>> import numpy as np
>>> x = np.array([[1,2,3]])
>>> y = np.array([[4],[5]])
>>> np.broadcast_arrays(x, y)
(array([[1, 2, 3],
        [1, 2, 3]]),
 array([[4, 4, 4],
        [5, 5, 5]]))
```

Here is a useful idiom for getting contiguous copies instead of non-contiguous views.

```
>>> [np.array(a) for a in np.broadcast_arrays(x, y)]
[array([[1, 2, 3],
        [1, 2, 3]]),
 array([[4, 4, 4],
        [5, 5, 5]])]
```

`numpy.expand_dims(a, axis)`

Expand the shape of an array.

Insert a new axis that will appear at the *axis* position in the expanded array shape.

Parameters

a
[array_like] Input array.

axis
[int or tuple of ints] Position in the expanded axes where the new axis (or axes) is placed.

Deprecated since version 1.13.0: Passing an axis where `axis > a.ndim` will be treated as `axis == a.ndim`, and passing `axis < -a.ndim - 1` will be treated as `axis == 0`. This behavior is deprecated.

Returns

result
[ndarray] View of *a* with the number of dimensions increased.

See also:

squeeze
The inverse operation, removing singleton dimensions

reshape
Insert, remove, and combine dimensions, and resize existing ones

atleast_1d, *atleast_2d*, *atleast_3d*

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2])
>>> x.shape
(2,)
```

The following is equivalent to `x[np.newaxis, :]` or `x[np.newaxis:]`:

```
>>> y = np.expand_dims(x, axis=0)
>>> y
array([[1, 2]])
>>> y.shape
(1, 2)
```

The following is equivalent to `x[:, np.newaxis]`:

```
>>> y = np.expand_dims(x, axis=1)
>>> y
array([[1],
       [2]])
>>> y.shape
(2, 1)
```

`axis` may also be a tuple:

```
>>> y = np.expand_dims(x, axis=(0, 1))
>>> y
array([[[1, 2]]])
```

```
>>> y = np.expand_dims(x, axis=(2, 0))
>>> y
array([[[[1],
         [2]]]])
```

Note that some examples may use `None` instead of `np.newaxis`. These are the same objects:

```
>>> np.newaxis is None
True
```

`numpy.squeeze(a, axis=None)`

Remove axes of length one from *a*.

Parameters

a

[array_like] Input data.

axis

[None or int or tuple of ints, optional] Selects a subset of the entries of length one in the shape. If an axis is selected with shape entry greater than one, an error is raised.

Returns

squeezed

[ndarray] The input array, but with all or a subset of the dimensions of length 1 removed. This is always *a* itself or a view into *a*. Note that if all axes are squeezed, the result is a 0d array and not a scalar.

Raises**ValueError**

If *axis* is not None, and an axis being squeezed is not of length 1

See also:*expand_dims*

The inverse operation, adding entries of length one

reshape

Insert, remove, and combine dimensions, and resize existing ones

Examples

```
>>> import numpy as np
>>> x = np.array([[[0], [1], [2]]])
>>> x.shape
(1, 3, 1)
>>> np.squeeze(x).shape
(3,)
>>> np.squeeze(x, axis=0).shape
(3, 1)
>>> np.squeeze(x, axis=1).shape
Traceback (most recent call last):
...
ValueError: cannot select an axis to squeeze out which has size
not equal to one
>>> np.squeeze(x, axis=2).shape
(1, 3)
>>> x = np.array([[1234]])
>>> x.shape
(1, 1)
>>> np.squeeze(x)
array(1234) # 0d array
>>> np.squeeze(x).shape
()
>>> np.squeeze(x) [()]
1234
```

Changing kind of array

<i>asarray</i> (a[, dtype, order, device, copy, like])	Convert the input to an array.
<i>asanyarray</i> (a[, dtype, order, device, copy, like])	Convert the input to an ndarray, but pass ndarray subclasses through.
<i>asmatrix</i> (data[, dtype])	Interpret the input as a matrix.
<i>asfortranarray</i> (a[, dtype, like])	Return an array (ndim >= 1) laid out in Fortran order in memory.
<i>ascontiguousarray</i> (a[, dtype, like])	Return a contiguous array (ndim >= 1) in memory (C order).
<i>asarray_chkfinite</i> (a[, dtype, order])	Convert the input to an array, checking for NaNs or Infs.
<i>require</i> (a[, dtype, requirements, like])	Return an ndarray of the provided type that satisfies requirements.

`numpy.asfortranarray` (*a*, *dtype=None*, *, *like=None*)

Return an array (ndim >= 1) laid out in Fortran order in memory.

Parameters

a

[array_like] Input array.

dtype

[str or dtype object, optional] By default, the data-type is inferred from the input data.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as *like* supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[ndarray] The input *a* in Fortran, or column-major, order.

See also:

[`ascontiguousarray`](#)

Convert input to a contiguous (C order) array.

[`asanyarray`](#)

Convert input to an ndarray with either row or column-major memory order.

[`require`](#)

Return an ndarray that satisfies requirements.

[`ndarray.flags`](#)

Information about the memory layout of the array.

Examples

Starting with a C-contiguous array:

```
>>> import numpy as np
>>> x = np.ones((2, 3), order='C')
>>> x.flags['C_CONTIGUOUS']
True
```

Calling `asfortranarray` makes a Fortran-contiguous copy:

```
>>> y = np.asfortranarray(x)
>>> y.flags['F_CONTIGUOUS']
True
>>> np.may_share_memory(x, y)
False
```

Now, starting with a Fortran-contiguous array:

```
>>> x = np.ones((2, 3), order='F')
>>> x.flags['F_CONTIGUOUS']
True
```

Then, calling `asfortranarray` returns the same object:

```
>>> y = np.asfortranarray(x)
>>> x is y
True
```

Note: This function returns an array with at least one-dimension (1-d) so it will not preserve 0-d arrays.

`numpy.asarray_chkfinite` (*a*, *dtype=None*, *order=None*)

Convert the input to an array, checking for NaNs or Infs.

Parameters

a

[array_like] Input data, in any form that can be converted to an array. This includes lists, lists of tuples, tuples, tuples of tuples, tuples of lists and ndarrays. Success requires no NaNs or Infs.

dtype

[data-type, optional] By default, the data-type is inferred from the input data.

order

[{'C', 'F', 'A', 'K'}, optional] The memory layout of the output. 'C' gives a row-major layout (C-style), 'F' gives a column-major layout (Fortran-style). 'C' and 'F' will copy if needed to ensure the output format. 'A' (any) is equivalent to 'F' if input *a* is non-contiguous or Fortran-contiguous, otherwise, it is equivalent to 'C'. Unlike 'C' or 'F', 'A' does not ensure that the result is contiguous. 'K' (keep) preserves the input order for the output. 'C' is the default.

Returns

out

[ndarray] Array interpretation of *a*. No copy is performed if the input is already an ndarray. If *a* is a subclass of ndarray, a base class ndarray is returned.

Raises

ValueError

Raises `ValueError` if *a* contains NaN (Not a Number) or Inf (Infinity).

See also:

`asarray`

Create and array.

`asanyarray`

Similar function which passes through subclasses.

`ascontiguousarray`

Convert input to a contiguous array.

`asfortranarray`

Convert input to an ndarray with column-major memory order.

`fromiter`

Create an array from an iterator.

`fromfunction`

Construct an array by executing a function on grid positions.

Examples

```
>>> import numpy as np
```

Convert a list into an array. If all elements are finite, then `asarray_chkfinite` is identical to `asarray`.

```
>>> a = [1, 2]
>>> np.asarray_chkfinite(a, dtype=np.float64)
array([1., 2.]
```

Raises `ValueError` if `array_like` contains Nans or Infs.

```
>>> a = [1, 2, np.inf]
>>> try:
...     np.asarray_chkfinite(a)
... except ValueError:
...     print('ValueError')
...
ValueError
```

`numpy.require(a, dtype=None, requirements=None, *, like=None)`

Return an ndarray of the provided type that satisfies requirements.

This function is useful to be sure that an array with the correct flags is returned for passing to compiled code (perhaps through ctypes).

Parameters

a

[array_like] The object to be converted to a type-and-requirement-satisfying array.

dtype

[data-type] The required data-type. If `None` preserve the current dtype. If your application requires the data to be in native byteorder, include a byteorder specification as a part of the dtype specification.

requirements

[str or sequence of str] The requirements list can be any of the following

- 'F_CONTIGUOUS' ('F') - ensure a Fortran-contiguous array
- 'C_CONTIGUOUS' ('C') - ensure a C-contiguous array
- 'ALIGNED' ('A') - ensure a data-type aligned array
- 'WRITEABLE' ('W') - ensure a writable array
- 'OWNDATA' ('O') - ensure an array that owns its own data
- 'ENSUREARRAY', ('E') - ensure a base array, instead of a subclass

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[ndarray] Array with specified requirements and type if given.

See also:

asarray

Convert input to an ndarray.

asanyarray

Convert to an ndarray, but pass through ndarray subclasses.

ascontiguousarray

Convert input to a contiguous array.

asfortranarray

Convert input to an ndarray with column-major memory order.

ndarray.flags

Information about the memory layout of the array.

Notes

The returned array will be guaranteed to have the listed requirements by making a copy if needed.

Examples

```
>>> import numpy as np
>>> x = np.arange(6).reshape(2,3)
>>> x.flags
C_CONTIGUOUS : True
F_CONTIGUOUS : False
OWNDATA : False
WRITEABLE : True
ALIGNED : True
WRITEBACKIFCOPY : False
```

```
>>> y = np.require(x, dtype=np.float32, requirements=['A', 'O', 'W', 'F'])
>>> y.flags
C_CONTIGUOUS : False
F_CONTIGUOUS : True
OWNDATA : True
WRITEABLE : True
ALIGNED : True
WRITEBACKIFCOPY : False
```

Joining arrays

<code>concatenate(arrays, /, axis, out, dtype, ...)</code>	Join a sequence of arrays along an existing axis.
<code>concat(arrays, /, axis, out, dtype, casting)</code>	Join a sequence of arrays along an existing axis.
<code>stack(arrays[, axis, out, dtype, casting])</code>	Join a sequence of arrays along a new axis.
<code>block(arrays)</code>	Assemble an nd-array from nested lists of blocks.
<code>vstack(tup, *, dtype, casting)</code>	Stack arrays in sequence vertically (row wise).
<code>hstack(tup, *, dtype, casting)</code>	Stack arrays in sequence horizontally (column wise).
<code>dstack(tup)</code>	Stack arrays in sequence depth wise (along third axis).
<code>column_stack(tup)</code>	Stack 1-D arrays as columns into a 2-D array.

`numpy.concatenate (arrays, /, axis=0, out=None, *, dtype=None, casting='same_kind')`

Join a sequence of arrays along an existing axis.

New in version 2.0: `numpy.concat` added as a shorthand for `numpy.concatenate`.

Parameters

a1, a2, ...

[sequence of array_like] The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).

axis

[int, optional] The axis along which the arrays will be joined. If *axis* is None, arrays are flattened before use. Default is 0.

out

[ndarray, optional] If provided, the destination to place the result. The shape must be correct, matching that of what `concatenate` would have returned if no *out* argument were specified.

dtype

[str or dtype] If provided, the destination array will have this dtype. Cannot be provided together with *out*.

New in version 1.20.0.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'same_kind'. For a description of the options, please see casting.

New in version 1.20.0.

Returns

res

[ndarray] The concatenated array.

See also:

`ma.concatenate`

Concatenate function that preserves input masks.

`array_split`

Split an array into multiple sub-arrays of equal or near-equal size.

`split`

Split array into a list of multiple sub-arrays of equal size.

`hsplit`

Split array into multiple sub-arrays horizontally (column wise).

vsplit

Split array into multiple sub-arrays vertically (row wise).

dsplit

Split array into multiple sub-arrays along the 3rd axis (depth).

stack

Stack a sequence of arrays along a new axis.

block

Assemble arrays from blocks.

hstack

Stack arrays in sequence horizontally (column wise).

vstack

Stack arrays in sequence vertically (row wise).

dstack

Stack arrays in sequence depth wise (along third dimension).

column_stack

Stack 1-D arrays as columns into a 2-D array.

Notes

When one or more of the arrays to be concatenated is a `MaskedArray`, this function will return a `MaskedArray` object instead of an `ndarray`, but the input masks are *not* preserved. In cases where a `MaskedArray` is expected as input, use the `ma.concatenate` function from the masked array module instead.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> b = np.array([[5, 6]])
>>> np.concatenate((a, b), axis=0)
array([[1, 2],
       [3, 4],
       [5, 6]])
>>> np.concatenate((a, b.T), axis=1)
array([[1, 2, 5],
       [3, 4, 6]])
>>> np.concatenate((a, b), axis=None)
array([1, 2, 3, 4, 5, 6])
```

This function will not preserve masking of `MaskedArray` inputs.

```
>>> a = np.ma.arange(3)
>>> a[1] = np.ma.masked
>>> b = np.arange(2, 5)
>>> a
masked_array(data=[0, --, 2],
             mask=[False,  True,  False],
             fill_value=999999)
>>> b
array([2, 3, 4])
>>> np.concatenate([a, b])
```

(continues on next page)

(continued from previous page)

```
masked_array(data=[0, 1, 2, 2, 3, 4],
             mask=False,
             fill_value=999999)
>>> np.ma.concatenate([a, b])
masked_array(data=[0, --, 2, 2, 3, 4],
             mask=[False,  True, False, False, False, False],
             fill_value=999999)
```

`numpy.concat` (*arrays*, /, *axis*=0, *out*=None, *, *dtype*=None, *casting*='same_kind')

Join a sequence of arrays along an existing axis.

New in version 2.0: `numpy.concat` added as a shorthand for `numpy.concatenate`.

Parameters

a1, a2, ...

[sequence of array_like] The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).

axis

[int, optional] The axis along which the arrays will be joined. If *axis* is None, arrays are flattened before use. Default is 0.

out

[ndarray, optional] If provided, the destination to place the result. The shape must be correct, matching that of what `concatenate` would have returned if no *out* argument were specified.

dtype

[str or dtype] If provided, the destination array will have this dtype. Cannot be provided together with *out*.

New in version 1.20.0.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'same_kind'. For a description of the options, please see casting.

New in version 1.20.0.

Returns

res

[ndarray] The concatenated array.

See also:

`ma.concatenate`

Concatenate function that preserves input masks.

`array_split`

Split an array into multiple sub-arrays of equal or near-equal size.

`split`

Split array into a list of multiple sub-arrays of equal size.

`hsplit`

Split array into multiple sub-arrays horizontally (column wise).

`vsplit`

Split array into multiple sub-arrays vertically (row wise).

dsplit

Split array into multiple sub-arrays along the 3rd axis (depth).

stack

Stack a sequence of arrays along a new axis.

block

Assemble arrays from blocks.

hstack

Stack arrays in sequence horizontally (column wise).

vstack

Stack arrays in sequence vertically (row wise).

dstack

Stack arrays in sequence depth wise (along third dimension).

column_stack

Stack 1-D arrays as columns into a 2-D array.

Notes

When one or more of the arrays to be concatenated is a `MaskedArray`, this function will return a `MaskedArray` object instead of an `ndarray`, but the input masks are *not* preserved. In cases where a `MaskedArray` is expected as input, use the `ma.concatenate` function from the masked array module instead.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4]])
>>> b = np.array([[5, 6]])
>>> np.concatenate((a, b), axis=0)
array([[1, 2],
       [3, 4],
       [5, 6]])
>>> np.concatenate((a, b.T), axis=1)
array([[1, 2, 5],
       [3, 4, 6]])
>>> np.concatenate((a, b), axis=None)
array([1, 2, 3, 4, 5, 6])
```

This function will not preserve masking of `MaskedArray` inputs.

```
>>> a = np.ma.arange(3)
>>> a[1] = np.ma.masked
>>> b = np.arange(2, 5)
>>> a
masked_array(data=[0, --, 2],
             mask=[False,  True,  False],
             fill_value=999999)
>>> b
array([2, 3, 4])
>>> np.concatenate([a, b])
masked_array(data=[0, 1, 2, 2, 3, 4],
             mask=False,
             fill_value=999999)
```

(continues on next page)

(continued from previous page)

```
>>> np.ma.concatenate([a, b])
masked_array(data=[0, --, 2, 2, 3, 4],
              mask=[False,  True, False, False, False, False],
              fill_value=999999)
```

`numpy.stack` (*arrays*, *axis=0*, *out=None*, ***, *dtype=None*, *casting='same_kind'*)

Join a sequence of arrays along a new axis.

The *axis* parameter specifies the index of the new axis in the dimensions of the result. For example, if *axis=0* it will be the first dimension and if *axis=-1* it will be the last dimension.

Parameters

arrays

[sequence of ndarrays] Each array must have the same shape. In the case of a single ndarray array_like input, it will be treated as a sequence of arrays; i.e., each element along the zeroth axis is treated as a separate array.

axis

[int, optional] The axis in the result array along which the input arrays are stacked.

out

[ndarray, optional] If provided, the destination to place the result. The shape must be correct, matching that of what stack would have returned if no out argument were specified.

dtype

[str or dtype] If provided, the destination array will have this dtype. Cannot be provided together with *out*.

New in version 1.24.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'same_kind'.

New in version 1.24.

Returns

stacked

[ndarray] The stacked array has one more dimension than the input arrays.

See also:

concatenate

Join a sequence of arrays along an existing axis.

block

Assemble an nd-array from nested lists of blocks.

split

Split array into a list of multiple sub-arrays of equal size.

unstack

Split an array into a tuple of sub-arrays along an axis.

Examples

```
>>> import numpy as np
>>> rng = np.random.default_rng()
>>> arrays = [rng.normal(size=(3,4)) for _ in range(10)]
>>> np.stack(arrays, axis=0).shape
(10, 3, 4)
```

```
>>> np.stack(arrays, axis=1).shape
(3, 10, 4)
```

```
>>> np.stack(arrays, axis=2).shape
(3, 4, 10)
```

```
>>> a = np.array([1, 2, 3])
>>> b = np.array([4, 5, 6])
>>> np.stack((a, b))
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> np.stack((a, b), axis=-1)
array([[1, 4],
       [2, 5],
       [3, 6]])
```

`numpy.block` (*arrays*)

Assemble an nd-array from nested lists of blocks.

Blocks in the innermost lists are concatenated (see [concatenate](#)) along the last dimension (-1), then these are concatenated along the second-last dimension (-2), and so on until the outermost list is reached.

Blocks can be of any dimension, but will not be broadcasted using the normal rules. Instead, leading axes of size 1 are inserted, to make `block.ndim` the same for all blocks. This is primarily useful for working with scalars, and means that code like `np.block([v, 1])` is valid, where `v.ndim == 1`.

When the nested list is two levels deep, this allows block matrices to be constructed from their components.

Parameters

arrays

[nested list of array_like or scalars (but not tuples)] If passed a single ndarray or scalar (a nested list of depth 0), this is returned unmodified (and not copied).

Elements shapes must match along the appropriate axes (without broadcasting), but leading 1s will be prepended to the shape as necessary to make the dimensions match.

Returns

block_array

[ndarray] The array assembled from the given blocks.

The dimensionality of the output is equal to the greatest of:

- the dimensionality of all the inputs
- the depth to which the input list is nested

Raises

ValueError

- If list depths are mismatched - for instance, `[[a, b], c]` is illegal, and should be spelt `[[a, b], [c]]`
- If lists are empty - for instance, `[[a, b], []]`

See also:

concatenate

Join a sequence of arrays along an existing axis.

stack

Join a sequence of arrays along a new axis.

vstack

Stack arrays in sequence vertically (row wise).

hstack

Stack arrays in sequence horizontally (column wise).

dstack

Stack arrays in sequence depth wise (along third axis).

column_stack

Stack 1-D arrays as columns into a 2-D array.

vsplit

Split an array into multiple sub-arrays vertically (row-wise).

unstack

Split an array into a tuple of sub-arrays along an axis.

Notes

When called with only scalars, `np.block` is equivalent to an `ndarray` call. So `np.block([[1, 2], [3, 4]])` is equivalent to `np.array([[1, 2], [3, 4]])`.

This function does not enforce that the blocks lie on a fixed grid. `np.block([[a, b], [c, d]])` is not restricted to arrays of the form:

```
AAAbb
AAAbb
cccDD
```

But is also allowed to produce, for some `a`, `b`, `c`, `d`:

```
AAAbb
AAAbb
cDDDD
```

Since concatenation happens along the last axis first, *block* is *not* capable of producing the following directly:

```
AAAbb
cccb
cccDD
```

Matlab's "square bracket stacking", `[A, B, ...; p, q, ...]`, is equivalent to `np.block([A, B, ...], [p, q, ...])`.

Examples

The most common use of this function is to build a block matrix:

```
>>> import numpy as np
>>> A = np.eye(2) * 2
>>> B = np.eye(3) * 3
>>> np.block([
...     [A,          np.zeros((2, 3))],
...     [np.ones((3, 2)), B
...     ]
... ])
array([[2., 0., 0., 0., 0.],
       [0., 2., 0., 0., 0.],
       [1., 1., 3., 0., 0.],
       [1., 1., 0., 3., 0.],
       [1., 1., 0., 0., 3.]])
```

With a list of depth 1, *block* can be used as *hstack*:

```
>>> np.block([1, 2, 3])           # hstack([1, 2, 3])
array([1, 2, 3])
```

```
>>> a = np.array([1, 2, 3])
>>> b = np.array([4, 5, 6])
>>> np.block([a, b, 10])          # hstack([a, b, 10])
array([ 1,  2,  3,  4,  5,  6, 10])
```

```
>>> A = np.ones((2, 2), int)
>>> B = 2 * A
>>> np.block([A, B])              # hstack([A, B])
array([[1, 1, 2, 2],
       [1, 1, 2, 2]])
```

With a list of depth 2, *block* can be used in place of *vstack*:

```
>>> a = np.array([1, 2, 3])
>>> b = np.array([4, 5, 6])
>>> np.block([a], [b])            # vstack([a, b])
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> A = np.ones((2, 2), int)
>>> B = 2 * A
>>> np.block([A], [B])            # vstack([A, B])
array([[1, 1],
       [1, 1],
       [2, 2],
       [2, 2]])
```

It can also be used in place of *atleast_1d* and *atleast_2d*:

```
>>> a = np.array(0)
>>> b = np.array([1])
>>> np.block([a])                 # atleast_1d(a)
array([0])
>>> np.block([b])                 # atleast_1d(b)
array([1])
```

```

>>> np.block([[a]])           # atleast_2d(a)
array([[0]])
>>> np.block([[b]])           # atleast_2d(b)
array([[1]])

```

`numpy.vstack` (*tup*, *, *dtype=None*, *casting='same_kind'*)

Stack arrays in sequence vertically (row wise).

This is equivalent to concatenation along the first axis after 1-D arrays of shape $(N,)$ have been reshaped to $(1,N)$. Rebuilds arrays divided by *vsplit*.

This function makes most sense for arrays with up to 3 dimensions. For instance, for pixel-data with a height (first axis), width (second axis), and r/g/b channels (third axis). The functions *concatenate*, *stack* and *block* provide more general stacking and concatenation operations.

Parameters

tup

[sequence of ndarrays] The arrays must have the same shape along all but the first axis. 1-D arrays must have the same length. In the case of a single array_like input, it will be treated as a sequence of arrays; i.e., each element along the zeroth axis is treated as a separate array.

dtype

[str or dtype] If provided, the destination array will have this dtype. Cannot be provided together with *out*.

New in version 1.24.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'same_kind'.

New in version 1.24.

Returns

stacked

[ndarray] The array formed by stacking the given arrays, will be at least 2-D.

See also:

concatenate

Join a sequence of arrays along an existing axis.

stack

Join a sequence of arrays along a new axis.

block

Assemble an nd-array from nested lists of blocks.

hstack

Stack arrays in sequence horizontally (column wise).

dstack

Stack arrays in sequence depth wise (along third axis).

column_stack

Stack 1-D arrays as columns into a 2-D array.

vsplit

Split an array into multiple sub-arrays vertically (row-wise).

unstack

Split an array into a tuple of sub-arrays along an axis.

Examples

```
>>> import numpy as np
>>> a = np.array([1, 2, 3])
>>> b = np.array([4, 5, 6])
>>> np.vstack((a,b))
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> a = np.array([[1], [2], [3]])
>>> b = np.array([[4], [5], [6]])
>>> np.vstack((a,b))
array([[1],
       [2],
       [3],
       [4],
       [5],
       [6]])
```

`numpy.hstack(tup, *, dtype=None, casting='same_kind')`

Stack arrays in sequence horizontally (column wise).

This is equivalent to concatenation along the second axis, except for 1-D arrays where it concatenates along the first axis. Rebuilds arrays divided by [hsplit](#).

This function makes most sense for arrays with up to 3 dimensions. For instance, for pixel-data with a height (first axis), width (second axis), and r/g/b channels (third axis). The functions [concatenate](#), [stack](#) and [block](#) provide more general stacking and concatenation operations.

Parameters**tup**

[sequence of ndarrays] The arrays must have the same shape along all but the second axis, except 1-D arrays which can be any length. In the case of a single array_like input, it will be treated as a sequence of arrays; i.e., each element along the zeroth axis is treated as a separate array.

dtype

[str or dtype] If provided, the destination array will have this dtype. Cannot be provided together with *out*.

New in version 1.24.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur. Defaults to 'same_kind'.

New in version 1.24.

Returns**stacked**

[ndarray] The array formed by stacking the given arrays.

See also:

concatenate

Join a sequence of arrays along an existing axis.

stack

Join a sequence of arrays along a new axis.

block

Assemble an nd-array from nested lists of blocks.

vstack

Stack arrays in sequence vertically (row wise).

dstack

Stack arrays in sequence depth wise (along third axis).

column_stack

Stack 1-D arrays as columns into a 2-D array.

hsplit

Split an array into multiple sub-arrays horizontally (column-wise).

unstack

Split an array into a tuple of sub-arrays along an axis.

Examples

```
>>> import numpy as np
>>> a = np.array((1,2,3))
>>> b = np.array((4,5,6))
>>> np.hstack((a,b))
array([1, 2, 3, 4, 5, 6])
>>> a = np.array([[1],[2],[3]])
>>> b = np.array([[4],[5],[6]])
>>> np.hstack((a,b))
array([[1, 4],
       [2, 5],
       [3, 6]])
```

`numpy.dstack(tup)`

Stack arrays in sequence depth wise (along third axis).

This is equivalent to concatenation along the third axis after 2-D arrays of shape (M,N) have been reshaped to $(M,N,1)$ and 1-D arrays of shape $(N,)$ have been reshaped to $(1,N,1)$. Rebuilds arrays divided by *dsplit*.

This function makes most sense for arrays with up to 3 dimensions. For instance, for pixel-data with a height (first axis), width (second axis), and r/g/b channels (third axis). The functions *concatenate*, *stack* and *block* provide more general stacking and concatenation operations.

Parameters**tup**

[sequence of arrays] The arrays must have the same shape along all but the third axis. 1-D or 2-D arrays must have the same shape.

Returns**stacked**

[ndarray] The array formed by stacking the given arrays, will be at least 3-D.

See also:

concatenate

Join a sequence of arrays along an existing axis.

stack

Join a sequence of arrays along a new axis.

block

Assemble an nd-array from nested lists of blocks.

vstack

Stack arrays in sequence vertically (row wise).

hstack

Stack arrays in sequence horizontally (column wise).

column_stack

Stack 1-D arrays as columns into a 2-D array.

dsplit

Split array along third axis.

Examples

```
>>> import numpy as np
>>> a = np.array((1,2,3))
>>> b = np.array((4,5,6))
>>> np.dstack((a,b))
array([[1, 4],
       [2, 5],
       [3, 6]])
```

```
>>> a = np.array([[1],[2],[3]])
>>> b = np.array([[4],[5],[6]])
>>> np.dstack((a,b))
array([[1, 4],
       [2, 5],
       [3, 6]])
```

`numpy.column_stack(tup)`

Stack 1-D arrays as columns into a 2-D array.

Take a sequence of 1-D arrays and stack them as columns to make a single 2-D array. 2-D arrays are stacked as-is, just like with *hstack*. 1-D arrays are turned into 2-D columns first.

Parameters***tup***

[sequence of 1-D or 2-D arrays.] Arrays to stack. All of them must have the same first dimension.

Returns***stacked***

[2-D array] The array formed by stacking the given arrays.

See also:

stack, *hstack*, *vstack*, *concatenate*

Examples

```
>>> import numpy as np
>>> a = np.array((1,2,3))
>>> b = np.array((4,5,6))
>>> np.column_stack((a,b))
array([[1, 4],
       [2, 5],
       [3, 6]])
```

Splitting arrays

<code>split(ary, indices_or_sections[, axis])</code>	Split an array into multiple sub-arrays as views into <i>ary</i> .
<code>array_split(ary, indices_or_sections[, axis])</code>	Split an array into multiple sub-arrays.
<code>dsplit(ary, indices_or_sections)</code>	Split array into multiple sub-arrays along the 3rd axis (depth).
<code>hsplit(ary, indices_or_sections)</code>	Split an array into multiple sub-arrays horizontally (column-wise).
<code>vsplit(ary, indices_or_sections)</code>	Split an array into multiple sub-arrays vertically (row-wise).
<code>unstack(x, /, *, axis)</code>	Split an array into a sequence of arrays along the given axis.

`numpy.split(ary, indices_or_sections, axis=0)`

Split an array into multiple sub-arrays as views into *ary*.

Parameters

ary

[ndarray] Array to be divided into sub-arrays.

indices_or_sections

[int or 1-D array] If *indices_or_sections* is an integer, N, the array will be divided into N equal arrays along *axis*. If such a split is not possible, an error is raised.

If *indices_or_sections* is a 1-D array of sorted integers, the entries indicate where along *axis* the array is split. For example, `[2, 3]` would, for `axis=0`, result in

- `ary[:2]`
- `ary[2:3]`
- `ary[3:]`

If an index exceeds the dimension of the array along *axis*, an empty sub-array is returned correspondingly.

axis

[int, optional] The axis along which to split, default is 0.

Returns

sub-arrays

[list of ndarrays] A list of sub-arrays as views into *ary*.

Raises

ValueError

If *indices_or_sections* is given as an integer, but a split does not result in equal division.

See also:

array_split

Split an array into multiple sub-arrays of equal or near-equal size. Does not raise an exception if an equal division cannot be made.

hsplit

Split array into multiple sub-arrays horizontally (column-wise).

vsplit

Split array into multiple sub-arrays vertically (row wise).

dsplit

Split array into multiple sub-arrays along the 3rd axis (depth).

concatenate

Join a sequence of arrays along an existing axis.

stack

Join a sequence of arrays along a new axis.

hstack

Stack arrays in sequence horizontally (column wise).

vstack

Stack arrays in sequence vertically (row wise).

dstack

Stack arrays in sequence depth wise (along third dimension).

Examples

```
>>> import numpy as np
>>> x = np.arange(9.0)
>>> np.split(x, 3)
[array([0., 1., 2.]), array([3., 4., 5.]), array([6., 7., 8.])]
```

```
>>> x = np.arange(8.0)
>>> np.split(x, [3, 5, 6, 10])
[array([0., 1., 2.]),
 array([3., 4.]),
 array([5.]),
 array([6., 7.]),
 array([], dtype=float64)]
```

`numpy.array_split` (*ary, indices_or_sections, axis=0*)

Split an array into multiple sub-arrays.

Please refer to the `split` documentation. The only difference between these functions is that `array_split` allows *indices_or_sections* to be an integer that does *not* equally divide the axis. For an array of length *l* that should be split into *n* sections, it returns *l* % *n* sub-arrays of size *l*/*n* + 1 and the rest of size *l*/*n*.

See also:

split

Split array into multiple sub-arrays of equal size.

Examples

```
>>> import numpy as np
>>> x = np.arange(8.0)
>>> np.array_split(x, 3)
[array([0., 1., 2.]), array([3., 4., 5.]), array([6., 7.])]
```

```
>>> x = np.arange(9)
>>> np.array_split(x, 4)
[array([0, 1, 2]), array([3, 4]), array([5, 6]), array([7, 8])]
```

`numpy.dspl`**it** (*ary, indices_or_sections*)

Split array into multiple sub-arrays along the 3rd axis (depth).

Please refer to the [split](#) documentation. `dsplit` is equivalent to `split` with `axis=2`, the array is always split along the third axis provided the array dimension is greater than or equal to 3.

See also:

[split](#)

Split an array into multiple sub-arrays of equal size.

Examples

```
>>> import numpy as np
>>> x = np.arange(16.0).reshape(2, 2, 4)
>>> x
array([[[ 0.,  1.,  2.,  3.],
        [ 4.,  5.,  6.,  7.]],
       [[ 8.,  9., 10., 11.],
        [12., 13., 14., 15.]])
>>> np.dspl
```

`numpy.hspl`**it** (*ary, indices_or_sections*)

Split an array into multiple sub-arrays horizontally (column-wise).

Please refer to the [split](#) documentation. `hsplit` is equivalent to `split` with `axis=1`, the array is always split along the second axis except for 1-D arrays, where it is split at `axis=0`.

See also:

split

Split an array into multiple sub-arrays of equal size.

Examples

```
>>> import numpy as np
>>> x = np.arange(16.0).reshape(4, 4)
>>> x
array([[ 0.,  1.,  2.,  3.],
       [ 4.,  5.,  6.,  7.],
       [ 8.,  9., 10., 11.],
       [12., 13., 14., 15.]])
>>> np.hsplit(x, 2)
[array([[ 0.,  1.],
       [ 4.,  5.],
       [ 8.,  9.],
       [12., 13.]]) ,
 array([[ 2.,  3.],
       [ 6.,  7.],
       [10., 11.],
       [14., 15.]])]
>>> np.hsplit(x, np.array([3, 6]))
[array([[ 0.,  1.,  2.],
       [ 4.,  5.,  6.],
       [ 8.,  9., 10.],
       [12., 13., 14.]]) ,
 array([[ 3.],
       [ 7.],
       [11.],
       [15.]]) ,
 array([], shape=(4, 0), dtype=float64)]
```

With a higher dimensional array the split is still along the second axis.

```
>>> x = np.arange(8.0).reshape(2, 2, 2)
>>> x
array([[[0.,  1.],
       [2.,  3.]],
      [[4.,  5.],
       [6.,  7.]])])
>>> np.hsplit(x, 2)
[array([[[0.,  1.],
       [4.,  5.]]]) ,
 array([[[2.,  3.],
       [6.,  7.]]])]
```

With a 1-D array, the split is along axis 0.

```
>>> x = np.array([0, 1, 2, 3, 4, 5])
>>> np.hsplit(x, 2)
[array([0, 1, 2]), array([3, 4, 5])]
```

`numpy.vsplit` (*ary, indices_or_sections*)

Split an array into multiple sub-arrays vertically (row-wise).

Please refer to the `split` documentation. `vsplit` is equivalent to `split` with `axis=0` (default), the array is always split along the first axis regardless of the array dimension.

See also:

`split`

Split an array into multiple sub-arrays of equal size.

Examples

```
>>> import numpy as np
>>> x = np.arange(16.0).reshape(4, 4)
>>> x
array([[ 0.,  1.,  2.,  3.],
       [ 4.,  5.,  6.,  7.],
       [ 8.,  9., 10., 11.],
       [12., 13., 14., 15.]])
>>> np.vsplit(x, 2)
[array([[0., 1., 2., 3.],
       [4., 5., 6., 7.]])
, array([[ 8.,  9., 10., 11.],
       [12., 13., 14., 15.]])
]
>>> np.vsplit(x, np.array([3, 6]))
[array([[ 0.,  1.,  2.,  3.],
       [ 4.,  5.,  6.,  7.],
       [ 8.,  9., 10., 11.]])
, array([[12., 13., 14., 15.]])
, array([], shape=(0, 4), dtype=float64)]
```

With a higher dimensional array the split is still along the first axis.

```
>>> x = np.arange(8.0).reshape(2, 2, 2)
>>> x
array([[[0., 1.],
       [2., 3.]],
      [[4., 5.],
       [6., 7.]])
>>> np.vsplit(x, 2)
[array([[[0., 1.],
       [2., 3.]]])
, array([[[4., 5.],
       [6., 7.]])
]
```

`numpy.unstack(x, /, *, axis=0)`

Split an array into a sequence of arrays along the given axis.

The `axis` parameter specifies the dimension along which the array will be split. For example, if `axis=0` (the default) it will be the first dimension and if `axis=-1` it will be the last dimension.

The result is a tuple of arrays split along `axis`.

New in version 2.1.0.

Parameters

x

[ndarray] The array to be unstacked.

axis

[int, optional] Axis along which the array will be split. Default: 0.

Returns

unstacked

[tuple of ndarrays] The unstacked arrays.

See also:***stack***

Join a sequence of arrays along a new axis.

concatenate

Join a sequence of arrays along an existing axis.

block

Assemble an nd-array from nested lists of blocks.

split

Split array into a list of multiple sub-arrays of equal size.

Notes

`unstack` serves as the reverse operation of `stack`, i.e., `stack(unstack(x, axis=axis), axis=axis) == x`.

This function is equivalent to `tuple(np.moveaxis(x, axis, 0))`, since iterating on an array iterates along the first axis.

Examples

```
>>> arr = np.arange(24).reshape((2, 3, 4))
>>> np.unstack(arr)
(array([[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]]),
 array([[12, 13, 14, 15],
        [16, 17, 18, 19],
        [20, 21, 22, 23]]))
>>> np.unstack(arr, axis=1)
(array([[ 0,  1,  2,  3],
        [12, 13, 14, 15]]),
 array([[ 4,  5,  6,  7],
        [16, 17, 18, 19]]),
 array([[ 8,  9, 10, 11],
        [20, 21, 22, 23]]))
>>> arr2 = np.stack(np.unstack(arr, axis=1), axis=1)
>>> arr2.shape
(2, 3, 4)
>>> np.all(arr == arr2)
np.True_
```

Tiling arrays

<code>tile(A, reps)</code>	Construct an array by repeating A the number of times given by reps.
<code>repeat(a, repeats[, axis])</code>	Repeat each element of an array after themselves

`numpy.tile(A, reps)`

Construct an array by repeating A the number of times given by reps.

If *reps* has length *d*, the result will have dimension of `max(d, A.ndim)`.

If `A.ndim < d`, *A* is promoted to be *d*-dimensional by prepending new axes. So a shape (3,) array is promoted to (1, 3) for 2-D replication, or shape (1, 1, 3) for 3-D replication. If this is not the desired behavior, promote *A* to *d*-dimensions manually before calling this function.

If `A.ndim > d`, *reps* is promoted to `A.ndim` by prepending 1's to it. Thus for an *A* of shape (2, 3, 4, 5), a *reps* of (2, 2) is treated as (1, 1, 2, 2).

Note : Although tile may be used for broadcasting, it is strongly recommended to use numpy's broadcasting operations and functions.

Parameters

A

[array_like] The input array.

reps

[array_like] The number of repetitions of *A* along each axis.

Returns

c

[ndarray] The tiled output array.

See also:

[*repeat*](#)

Repeat elements of an array.

[*broadcast_to*](#)

Broadcast an array to a new shape

Examples

```
>>> import numpy as np
>>> a = np.array([0, 1, 2])
>>> np.tile(a, 2)
array([0, 1, 2, 0, 1, 2])
>>> np.tile(a, (2, 2))
array([[0, 1, 2, 0, 1, 2],
       [0, 1, 2, 0, 1, 2]])
>>> np.tile(a, (2, 1, 2))
array([[[0, 1, 2, 0, 1, 2]],
       [[0, 1, 2, 0, 1, 2]])])
```

```
>>> b = np.array([[1, 2], [3, 4]])
>>> np.tile(b, 2)
array([[1, 2, 1, 2],
       [3, 4, 3, 4]])
>>> np.tile(b, (2, 1))
array([[1, 2],
       [3, 4],
       [1, 2],
       [3, 4]])
```

```
>>> c = np.array([1, 2, 3, 4])
>>> np.tile(c, (4, 1))
array([[1, 2, 3, 4],
       [1, 2, 3, 4],
       [1, 2, 3, 4],
       [1, 2, 3, 4]])
```

`numpy.repeat(a, repeats, axis=None)`

Repeat each element of an array after themselves

Parameters

a

[array_like] Input array.

repeats

[int or array of ints] The number of repetitions for each element. *repeats* is broadcasted to fit the shape of the given axis.

axis

[int, optional] The axis along which to repeat values. By default, use the flattened input array, and return a flat output array.

Returns

repeated_array

[ndarray] Output array which has the same shape as *a*, except along the given axis.

See also:

[*tile*](#)

Tile an array.

[*unique*](#)

Find the unique elements of an array.

Examples

```
>>> import numpy as np
>>> np.repeat(3, 4)
array([3, 3, 3, 3])
>>> x = np.array([[1, 2], [3, 4]])
>>> np.repeat(x, 2)
array([1, 1, 2, 2, 3, 3, 4, 4])
>>> np.repeat(x, 3, axis=1)
array([[1, 1, 1, 2, 2, 2],
       [3, 3, 3, 4, 4, 4]])
```

(continues on next page)

(continued from previous page)

```
>>> np.repeat(x, [1, 2], axis=0)
array([[1, 2],
       [3, 4],
       [3, 4]])
```

Adding and removing elements

<code>delete(arr, obj[, axis])</code>	Return a new array with sub-arrays along an axis deleted.
<code>insert(arr, obj, values[, axis])</code>	Insert values along the given axis before the given indices.
<code>append(arr, values[, axis])</code>	Append values to the end of an array.
<code>resize(a, new_shape)</code>	Return a new array with the specified shape.
<code>trim_zeros(filt[, trim, axis])</code>	Remove values along a dimension which are zero along all other.
<code>unique(ar[, return_index, return_inverse, ...])</code>	Find the unique elements of an array.
<code>pad(array, pad_width[, mode])</code>	Pad an array.

`numpy.delete(arr, obj, axis=None)`

Return a new array with sub-arrays along an axis deleted. For a one dimensional array, this returns those entries not returned by `arr[obj]`.

Parameters

arr

[array_like] Input array.

obj

[slice, int, array-like of ints or bools] Indicate indices of sub-arrays to remove along the specified axis.

Changed in version 1.19.0: Boolean indices are now treated as a mask of elements to remove, rather than being cast to the integers 0 and 1.

axis

[int, optional] The axis along which to delete the subarray defined by *obj*. If *axis* is None, *obj* is applied to the flattened array.

Returns

out

[ndarray] A copy of *arr* with the elements specified by *obj* removed. Note that `delete` does not occur in-place. If *axis* is None, *out* is a flattened array.

See also:

`insert`

Insert elements into an array.

`append`

Append elements at the end of an array.

Notes

Often it is preferable to use a boolean mask. For example:

```
>>> arr = np.arange(12) + 1
>>> mask = np.ones(len(arr), dtype=np.bool)
>>> mask[[0,2,4]] = False
>>> result = arr[mask,...]
```

Is equivalent to `np.delete(arr, [0,2,4], axis=0)`, but allows further use of *mask*.

Examples

```
>>> import numpy as np
>>> arr = np.array([[1,2,3,4], [5,6,7,8], [9,10,11,12]])
>>> arr
array([[ 1,  2,  3,  4],
       [ 5,  6,  7,  8],
       [ 9, 10, 11, 12]])
>>> np.delete(arr, 1, 0)
array([[ 1,  2,  3,  4],
       [ 9, 10, 11, 12]])
```

```
>>> np.delete(arr, np.s_[:2], 1)
array([[ 2,  4],
       [ 6,  8],
       [10, 12]])
>>> np.delete(arr, [1,3,5], None)
array([ 1,  3,  5,  7,  8,  9, 10, 11, 12])
```

`numpy.insert(arr, obj, values, axis=None)`

Insert values along the given axis before the given indices.

Parameters

arr

[array_like] Input array.

obj

[slice, int, array-like of ints or bools] Object that defines the index or indices before which *values* is inserted.

Changed in version 2.1.2: Boolean indices are now treated as a mask of elements to insert, rather than being cast to the integers 0 and 1.

Support for multiple insertions when *obj* is a single scalar or a sequence with one element (similar to calling insert multiple times).

values

[array_like] Values to insert into *arr*. If the type of *values* is different from that of *arr*, *values* is converted to the type of *arr*. *values* should be shaped so that `arr[...,obj,...] = values` is legal.

axis

[int, optional] Axis along which to insert *values*. If *axis* is None then *arr* is flattened first.

Returns

out

[ndarray] A copy of *arr* with *values* inserted. Note that *insert* does not occur in-place: a new array is returned. If *axis* is None, *out* is a flattened array.

See also:*append*

Append elements at the end of an array.

concatenate

Join a sequence of arrays along an existing axis.

delete

Delete elements from an array.

Notes

Note that for higher dimensional inserts *obj*=0 behaves very different from *obj*=[0] just like *arr*[:,0,:] = *values* is different from *arr*[:,[0],:] = *values*. This is because of the difference between basic and advanced indexing.

Examples

```
>>> import numpy as np
>>> a = np.arange(6).reshape(3, 2)
>>> a
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> np.insert(a, 1, 6)
array([0, 6, 1, 2, 3, 4, 5])
>>> np.insert(a, 1, 6, axis=1)
array([[0, 6, 1],
       [2, 6, 3],
       [4, 6, 5]])
```

Difference between sequence and scalars, showing how *obj*=[1] behaves different from *obj*=1:

```
>>> np.insert(a, [1], [[7],[8],[9]], axis=1)
array([[0, 7, 1],
       [2, 8, 3],
       [4, 9, 5]])
>>> np.insert(a, 1, [[7],[8],[9]], axis=1)
array([[0, 7, 8, 9, 1],
       [2, 7, 8, 9, 3],
       [4, 7, 8, 9, 5]])
>>> np.array_equal(np.insert(a, 1, [7, 8, 9], axis=1),
...               np.insert(a, [1], [[7],[8],[9]], axis=1))
True
```

```
>>> b = a.flatten()
>>> b
array([0, 1, 2, 3, 4, 5])
>>> np.insert(b, [2, 2], [6, 7])
array([0, 1, 6, 7, 2, 3, 4, 5])
```

```
>>> np.insert(b, slice(2, 4), [7, 8])
array([0, 1, 7, 2, 8, 3, 4, 5])
```

```
>>> np.insert(b, [2, 2], [7.13, False]) # type casting
array([0, 1, 7, 0, 2, 3, 4, 5])
```

```
>>> x = np.arange(8).reshape(2, 4)
>>> idx = (1, 3)
>>> np.insert(x, idx, 999, axis=1)
array([[ 0, 999,  1,  2, 999,  3],
       [ 4, 999,  5,  6, 999,  7]])
```

`numpy.append(arr, values, axis=None)`

Append values to the end of an array.

Parameters

arr

[array_like] Values are appended to a copy of this array.

values

[array_like] These values are appended to a copy of *arr*. It must be of the correct shape (the same shape as *arr*, excluding *axis*). If *axis* is not specified, *values* can be any shape and will be flattened before use.

axis

[int, optional] The axis along which *values* are appended. If *axis* is not given, both *arr* and *values* are flattened before use.

Returns

append

[ndarray] A copy of *arr* with *values* appended to *axis*. Note that *append* does not occur in-place: a new array is allocated and filled. If *axis* is None, *out* is a flattened array.

See also:

insert

Insert elements into an array.

delete

Delete elements from an array.

Examples

```
>>> import numpy as np
>>> np.append([1, 2, 3], [[4, 5, 6], [7, 8, 9]])
array([1, 2, 3, ..., 7, 8, 9])
```

When *axis* is specified, *values* must have the correct shape.

```
>>> np.append([1, 2, 3], [4, 5, 6], [[7, 8, 9]], axis=0)
array([[1, 2, 3],
       [4, 5, 6],
       [7, 8, 9]])
```

```
>>> np.append([[1, 2, 3], [4, 5, 6]], [7, 8, 9], axis=0)
Traceback (most recent call last):
...
ValueError: all the input arrays must have same number of dimensions, but
the array at index 0 has 2 dimension(s) and the array at index 1 has 1
dimension(s)
```

```
>>> a = np.array([1, 2], dtype=np.int_)
>>> c = np.append(a, [])
>>> c
array([1., 2.])
>>> c.dtype
float64
```

Default dtype for empty ndarrays is `float64` thus making the output of dtype `float64` when appended with dtype `int64`

`numpy.resize(a, new_shape)`

Return a new array with the specified shape.

If the new array is larger than the original array, then the new array is filled with repeated copies of *a*. Note that this behavior is different from `a.resize(new_shape)` which fills with zeros instead of repeated copies of *a*.

Parameters

a
[array_like] Array to be resized.

new_shape
[int or tuple of int] Shape of resized array.

Returns

reshaped_array
[ndarray] The new array is formed from the data in the old array, repeated if necessary to fill out the required number of elements. The data are repeated iterating over the array in C-order.

See also:

`numpy.reshape`
Reshape an array without changing the total size.

`numpy.pad`
Enlarge and pad an array.

`numpy.repeat`
Repeat elements of an array.

`ndarray.resize`
resize an array in-place.

Notes

When the total size of the array does not change *reshape* should be used. In most other cases either indexing (to reduce the size) or padding (to increase the size) may be a more appropriate solution.

Warning: This functionality does **not** consider axes separately, i.e. it does not apply interpolation/extrapolation. It fills the return array with the required number of elements, iterating over *a* in C-order, disregarding axes (and cycling back from the start if the new shape is larger). This functionality is therefore not suitable to resize images, or data where each axis represents a separate and distinct entity.

Examples

```
>>> import numpy as np
>>> a = np.array([[0,1],[2,3]])
>>> np.resize(a, (2,3))
array([[0, 1, 2],
       [3, 0, 1]])
>>> np.resize(a, (1,4))
array([[0, 1, 2, 3]])
>>> np.resize(a, (2,4))
array([[0, 1, 2, 3],
       [0, 1, 2, 3]])
```

`numpy.trim_zeros` (*filt*, *trim*='fb', *axis*=None)

Remove values along a dimension which are zero along all other.

Parameters

filt

[array_like] Input array.

trim

[{"fb", "f", "b"}, optional] A string with 'f' representing trim from front and 'b' to trim from back. By default, zeros are trimmed on both sides. Front and back refer to the edges of a dimension, with "front" referring to the side with the lowest index 0, and "back" referring to the highest index (or index -1).

axis

[int or sequence, optional] If None, *filt* is cropped such that the smallest bounding box is returned that still contains all values which are not zero. If an axis is specified, *filt* will be sliced in that dimension only on the sides specified by *trim*. The remaining area will be the smallest that still contains all values which are not zero.

New in version 2.2.0.

Returns

trimmed

[ndarray or sequence] The result of trimming the input. The number of dimensions and the input data type are preserved.

Notes

For all-zero arrays, the first axis is trimmed first.

Examples

```
>>> import numpy as np
>>> a = np.array((0, 0, 0, 1, 2, 3, 0, 2, 1, 0))
>>> np.trim_zeros(a)
array([1, 2, 3, 0, 2, 1])
```

```
>>> np.trim_zeros(a, trim='b')
array([0, 0, 0, ..., 0, 2, 1])
```

Multiple dimensions are supported.

```
>>> b = np.array([[0, 0, 2, 3, 0, 0],
...               [0, 1, 0, 3, 0, 0],
...               [0, 0, 0, 0, 0, 0]])
>>> np.trim_zeros(b)
array([[0, 2, 3],
       [1, 0, 3]])
```

```
>>> np.trim_zeros(b, axis=-1)
array([[0, 2, 3],
       [1, 0, 3],
       [0, 0, 0]])
```

The input data type is preserved, list/tuple in means list/tuple out.

```
>>> np.trim_zeros([0, 1, 2, 0])
[1, 2]
```

`numpy.unique` (*ar*, *return_index=False*, *return_inverse=False*, *return_counts=False*, *axis=None*, *, *equal_nan=True*, *sorted=True*)

Find the unique elements of an array.

Returns the sorted unique elements of an array. There are three optional outputs in addition to the unique elements:

- the indices of the input array that give the unique values
- the indices of the unique array that reconstruct the input array
- the number of times each unique value comes up in the input array

Parameters

ar

[array_like] Input array. Unless *axis* is specified, this will be flattened if it is not already 1-D.

return_index

[bool, optional] If True, also return the indices of *ar* (along the specified axis, if provided, or in the flattened array) that result in the unique array.

return_inverse

[bool, optional] If True, also return the indices of the unique array (for the specified axis, if provided) that can be used to reconstruct *ar*.

return_counts

[bool, optional] If True, also return the number of times each unique item appears in *ar*.

axis

[int or None, optional] The axis to operate on. If None, *ar* will be flattened. If an integer, the subarrays indexed by the given axis will be flattened and treated as the elements of a 1-D array with the dimension of the given axis, see the notes for more details. Object arrays or structured arrays that contain objects are not supported if the *axis* kwarg is used. The default is None.

equal_nan

[bool, optional] If True, collapses multiple NaN values in the return array into one.

New in version 1.24.

sorted

[bool, optional] If True, the unique elements are sorted. Elements may be sorted in practice even if `sorted=False`, but this could change without notice.

New in version 2.3.

Returns**unique**

[ndarray] The sorted unique values.

unique_indices

[ndarray, optional] The indices of the first occurrences of the unique values in the original array. Only provided if *return_index* is True.

unique_inverse

[ndarray, optional] The indices to reconstruct the original array from the unique array. Only provided if *return_inverse* is True.

unique_counts

[ndarray, optional] The number of times each of the unique values comes up in the original array. Only provided if *return_counts* is True.

See also:***repeat***

Repeat elements of an array.

sort

Return a sorted copy of an array.

Notes

When an axis is specified the subarrays indexed by the axis are sorted. This is done by making the specified axis the first dimension of the array (move the axis to the first dimension to keep the order of the other axes) and then flattening the subarrays in C order. The flattened subarrays are then viewed as a structured type with each element given a label, with the effect that we end up with a 1-D array of structured types that can be treated in the same way as any other 1-D array. The result is that the flattened subarrays are sorted in lexicographic order starting with the first element.

Changed in version 1.21: Like `np.sort`, NaN will sort to the end of the values. For complex arrays all NaN values are considered equivalent (no matter whether the NaN is in the real or imaginary part). As the representant for the returned array the smallest one in the lexicographical order is chosen - see `np.sort` for how the lexicographical order is defined for complex arrays.

Changed in version 2.0: For multi-dimensional inputs, `unique_inverse` is reshaped such that the input can be reconstructed using `np.take(unique, unique_inverse, axis=axis)`. The result is now not 1-dimensional when `axis=None`.

Note that in NumPy 2.0.0 a higher dimensional array was returned also when `axis` was not `None`. This was reverted, but `inverse.reshape(-1)` can be used to ensure compatibility with both versions.

Examples

```
>>> import numpy as np
>>> np.unique([1, 1, 2, 2, 3, 3])
array([1, 2, 3])
>>> a = np.array([[1, 1], [2, 3]])
>>> np.unique(a)
array([1, 2, 3])
```

Return the unique rows of a 2D array

```
>>> a = np.array([[1, 0, 0], [1, 0, 0], [2, 3, 4]])
>>> np.unique(a, axis=0)
array([[1, 0, 0], [2, 3, 4]])
```

Return the indices of the original array that give the unique values:

```
>>> a = np.array(['a', 'b', 'b', 'c', 'a'])
>>> u, indices = np.unique(a, return_index=True)
>>> u
array(['a', 'b', 'c'], dtype='<U1')
>>> indices
array([0, 1, 3])
>>> a[indices]
array(['a', 'b', 'c'], dtype='<U1')
```

Reconstruct the input array from the unique values and inverse:

```
>>> a = np.array([1, 2, 6, 4, 2, 3, 2])
>>> u, indices = np.unique(a, return_inverse=True)
>>> u
array([1, 2, 3, 4, 6])
>>> indices
array([0, 1, 4, 3, 1, 2, 1])
>>> u[indices]
array([1, 2, 6, 4, 2, 3, 2])
```

Reconstruct the input values from the unique values and counts:

```
>>> a = np.array([1, 2, 6, 4, 2, 3, 2])
>>> values, counts = np.unique(a, return_counts=True)
>>> values
array([1, 2, 3, 4, 6])
>>> counts
array([1, 3, 1, 1, 1])
>>> np.repeat(values, counts)
array([1, 2, 2, 2, 3, 4, 6]) # original order not preserved
```

`numpy.pad(array, pad_width, mode='constant', **kwargs)`

Pad an array.

Parameters**array**

[array_like of rank N] The array to pad.

pad_width

[{sequence, array_like, int, dict}] Number of values padded to the edges of each axis. ((before_1, after_1), ... (before_N, after_N)) unique pad widths for each axis. (before, after) or ((before, after),) yields same before and after pad for each axis. (pad,) or int is a shortcut for before = after = pad width for all axes. If a dict, each key is an axis and its corresponding value is an int or int pair describing the padding (before, after) or pad width for that axis.

mode

[str or function, optional] One of the following string values or a user supplied function.

‘constant’ (default)

Pads with a constant value.

‘edge’

Pads with the edge values of array.

‘linear_ramp’

Pads with the linear ramp between end_value and the array edge value.

‘maximum’

Pads with the maximum value of all or part of the vector along each axis.

‘mean’

Pads with the mean value of all or part of the vector along each axis.

‘median’

Pads with the median value of all or part of the vector along each axis.

‘minimum’

Pads with the minimum value of all or part of the vector along each axis.

‘reflect’

Pads with the reflection of the vector mirrored on the first and last values of the vector along each axis.

‘symmetric’

Pads with the reflection of the vector mirrored along the edge of the array.

‘wrap’

Pads with the wrap of the vector along the axis. The first values are used to pad the end and the end values are used to pad the beginning.

‘empty’

Pads with undefined values.

<function>

Padding function, see Notes.

stat_length

[sequence or int, optional] Used in ‘maximum’, ‘mean’, ‘median’, and ‘minimum’. Number of values at edge of each axis used to calculate the statistic value.

((before_1, after_1), ... (before_N, after_N)) unique statistic lengths for each axis.

(before, after) or ((before, after),) yields same before and after statistic lengths for each axis.

(`stat_length,`) or `int` is a shortcut for `before = after = statistic length` for all axes.

Default is `None`, to use the entire axis.

constant_values

[sequence or scalar, optional] Used in 'constant'. The values to set the padded values for each axis.

(`(before_1, after_1), ... (before_N, after_N)`) unique pad constants for each axis.

(`before, after`) or (`(before, after),`) yields same before and after constants for each axis.

(`constant,`) or `constant` is a shortcut for `before = after = constant` for all axes.

Default is 0.

end_values

[sequence or scalar, optional] Used in 'linear_ramp'. The values used for the ending value of the linear_ramp and that will form the edge of the padded array.

(`(before_1, after_1), ... (before_N, after_N)`) unique end values for each axis.

(`before, after`) or (`(before, after),`) yields same before and after end values for each axis.

(`constant,`) or `constant` is a shortcut for `before = after = constant` for all axes.

Default is 0.

reflect_type

[{'even', 'odd'}, optional] Used in 'reflect', and 'symmetric'. The 'even' style is the default with an unaltered reflection around the edge value. For the 'odd' style, the extended part of the array is created by subtracting the reflected values from two times the edge value.

Returns

pad

[ndarray] Padded array of rank equal to `array` with shape increased according to `pad_width`.

Notes

For an array with rank greater than 1, some of the padding of later axes is calculated from padding of previous axes. This is easiest to think about with a rank 2 array where the corners of the padded array are calculated by using padded values from the first axis.

The padding function, if used, should modify a rank 1 array in-place. It has the following signature:

```
padding_func(vector, iaxis_pad_width, iaxis, kwargs)
```

where

vector

[ndarray] A rank 1 array already padded with zeros. Padded values are `vector[:iaxis_pad_width[0]]` and `vector[-iaxis_pad_width[1]:]`.

iaxis_pad_width

[tuple] A 2-tuple of ints, `iaxis_pad_width[0]` represents the number of values padded at the beginning of vector where `iaxis_pad_width[1]` represents the number of values padded at the end of vector.

iaxis

[int] The axis currently being calculated.

kwargs

[dict] Any keyword arguments the function requires.

Examples

```
>>> import numpy as np
>>> a = [1, 2, 3, 4, 5]
>>> np.pad(a, (2, 3), 'constant', constant_values=(4, 6))
array([4, 4, 1, ..., 6, 6, 6])
```

```
>>> np.pad(a, (2, 3), 'edge')
array([1, 1, 1, ..., 5, 5, 5])
```

```
>>> np.pad(a, (2, 3), 'linear_ramp', end_values=(5, -4))
array([ 5,  3,  1,  2,  3,  4,  5,  2, -1, -4])
```

```
>>> np.pad(a, (2,), 'maximum')
array([5, 5, 1, 2, 3, 4, 5, 5, 5])
```

```
>>> np.pad(a, (2,), 'mean')
array([3, 3, 1, 2, 3, 4, 5, 3, 3])
```

```
>>> np.pad(a, (2,), 'median')
array([3, 3, 1, 2, 3, 4, 5, 3, 3])
```

```
>>> a = [[1, 2], [3, 4]]
>>> np.pad(a, ((3, 2), (2, 3)), 'minimum')
array([[1, 1, 1, 2, 1, 1, 1],
       [1, 1, 1, 2, 1, 1, 1],
       [1, 1, 1, 2, 1, 1, 1],
       [1, 1, 1, 2, 1, 1, 1],
       [3, 3, 3, 4, 3, 3, 3],
       [1, 1, 1, 2, 1, 1, 1],
       [1, 1, 1, 2, 1, 1, 1]])
```

```
>>> a = [1, 2, 3, 4, 5]
>>> np.pad(a, (2, 3), 'reflect')
array([3, 2, 1, 2, 3, 4, 5, 4, 3, 2])
```

```
>>> np.pad(a, (2, 3), 'reflect', reflect_type='odd')
array([-1,  0,  1,  2,  3,  4,  5,  6,  7,  8])
```

```
>>> np.pad(a, (2, 3), 'symmetric')
array([2, 1, 1, 2, 3, 4, 5, 5, 4, 3])
```

```
>>> np.pad(a, (2, 3), 'symmetric', reflect_type='odd')
array([0, 1, 1, 2, 3, 4, 5, 5, 6, 7])
```

```
>>> np.pad(a, (2, 3), 'wrap')
array([4, 5, 1, 2, 3, 4, 5, 1, 2, 3])
```

```
>>> def pad_with(vector, pad_width, iaxis, kwargs):
...     pad_value = kwargs.get('padder', 10)
...     vector[:pad_width[0]] = pad_value
...     vector[-pad_width[1]:] = pad_value
>>> a = np.arange(6)
>>> a = a.reshape((2, 3))
>>> np.pad(a, 2, pad_with)
array([[10, 10, 10, 10, 10, 10, 10],
       [10, 10, 10, 10, 10, 10, 10],
       [10, 10,  0,  1,  2, 10, 10],
       [10, 10,  3,  4,  5, 10, 10],
       [10, 10, 10, 10, 10, 10, 10],
       [10, 10, 10, 10, 10, 10, 10]])
>>> np.pad(a, 2, pad_with, padder=100)
array([[100, 100, 100, 100, 100, 100, 100],
       [100, 100, 100, 100, 100, 100, 100],
       [100, 100,  0,  1,  2, 100, 100],
       [100, 100,  3,  4,  5, 100, 100],
       [100, 100, 100, 100, 100, 100, 100],
       [100, 100, 100, 100, 100, 100, 100]])
```

```
>>> a = np.arange(1, 7).reshape(2, 3)
>>> np.pad(a, {1: (1, 2)})
array([[0, 1, 2, 3, 0, 0],
       [0, 4, 5, 6, 0, 0]])
>>> np.pad(a, {-1: 2})
array([[0, 0, 1, 2, 3, 0, 0],
       [0, 0, 4, 5, 6, 0, 0]])
>>> np.pad(a, {0: (3, 0)})
array([[0, 0, 0],
       [0, 0, 0],
       [0, 0, 0],
       [1, 2, 3],
       [4, 5, 6]])
>>> np.pad(a, {0: (3, 0), 1: 2})
array([[0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0],
       [0, 0, 1, 2, 3, 0, 0],
       [0, 0, 4, 5, 6, 0, 0]])
```

Rearranging elements

<code>flip(m[, axis])</code>	Reverse the order of elements in an array along the given axis.
<code>fliplr(m)</code>	Reverse the order of elements along axis 1 (left/right).
<code>flipud(m)</code>	Reverse the order of elements along axis 0 (up/down).
<code>roll(a, shift[, axis])</code>	Roll array elements along a given axis.
<code>rot90(m[, k, axes])</code>	Rotate an array by 90 degrees in the plane specified by axes.

`numpy.flip(m, axis=None)`

Reverse the order of elements in an array along the given axis.

The shape of the array is preserved, but the elements are reordered.

Parameters

m

[array_like] Input array.

axis

[None or int or tuple of ints, optional] Axis or axes along which to flip over. The default, axis=None, will flip over all of the axes of the input array. If axis is negative it counts from the last to the first axis.

If axis is a tuple of ints, flipping is performed on all of the axes specified in the tuple.

Returns

out

[array_like] A view of *m* with the entries of axis reversed. Since a view is returned, this operation is done in constant time.

See also:

[*flipud*](#)

Flip an array vertically (axis=0).

[*fliplr*](#)

Flip an array horizontally (axis=1).

Notes

`flip(m, 0)` is equivalent to `flipud(m)`.

`flip(m, 1)` is equivalent to `fliplr(m)`.

`flip(m, n)` corresponds to `m[ ..., ::-1, ... ]` with `::-1` at position *n*.

`flip(m)` corresponds to `m[ ::-1, ::-1, ..., ::-1 ]` with `::-1` at all positions.

`flip(m, (0, 1))` corresponds to `m[ ::-1, ::-1, ... ]` with `::-1` at position 0 and position 1.

Examples

```
>>> import numpy as np
>>> A = np.arange(8).reshape((2,2,2))
>>> A
array([[[0, 1],
        [2, 3]],
       [[4, 5],
        [6, 7]]])
>>> np.flip(A, 0)
array([[[4, 5],
        [6, 7]],
       [[0, 1],
        [2, 3]]])
>>> np.flip(A, 1)
array([[[2, 3],
        [0, 1]],
       [[6, 7],
        [4, 5]]])
>>> np.flip(A)
array([[[7, 6],
        [5, 4]],
       [[3, 2],
        [1, 0]]])
>>> np.flip(A, (0, 2))
array([[[5, 4],
        [7, 6]],
       [[1, 0],
        [3, 2]]])
>>> rng = np.random.default_rng()
>>> A = rng.normal(size=(3,4,5))
>>> np.all(np.flip(A,2) == A[:, :, ::-1, ...])
True
```

numpy.**fliplr**(*m*)

Reverse the order of elements along axis 1 (left/right).

For a 2-D array, this flips the entries in each row in the left/right direction. Columns are preserved, but appear in a different order than before.

Parameters

m

[array_like] Input array, must be at least 2-D.

Returns

f

[ndarray] A view of *m* with the columns reversed. Since a view is returned, this operation is $\mathcal{O}(1)$.

See also:

flipud

Flip array in the up/down direction.

flip

Flip array in one or more dimensions.

rot90

Rotate array counterclockwise.

Notes

Equivalent to `m[:, ::-1]` or `np.flip(m, axis=1)`. Requires the array to be at least 2-D.

Examples

```
>>> import numpy as np
>>> A = np.diag([1., 2., 3.])
>>> A
array([[1.,  0.,  0.],
       [0.,  2.,  0.],
       [0.,  0.,  3.]])
>>> np.fliplr(A)
array([[0.,  0.,  1.],
       [0.,  2.,  0.],
       [3.,  0.,  0.]])
```

```
>>> rng = np.random.default_rng()
>>> A = rng.normal(size=(2, 3, 5))
>>> np.all(np.fliplr(A) == A[:, ::-1, ...])
True
```

`numpy.fliplr(m)`

Reverse the order of elements along axis 0 (up/down).

For a 2-D array, this flips the entries in each column in the up/down direction. Rows are preserved, but appear in a different order than before.

Parameters

m

[array_like] Input array.

Returns

out

[array_like] A view of *m* with the rows reversed. Since a view is returned, this operation is $\mathcal{O}(1)$.

See also:

fliplr

Flip array in the left/right direction.

flip

Flip array in one or more dimensions.

rot90

Rotate array counterclockwise.

Notes

Equivalent to `m[::-1, ...]` or `np.flip(m, axis=0)`. Requires the array to be at least 1-D.

Examples

```
>>> import numpy as np
>>> A = np.diag([1.0, 2, 3])
>>> A
array([[1.,  0.,  0.],
       [0.,  2.,  0.],
       [0.,  0.,  3.]])
>>> np.flipud(A)
array([[0.,  0.,  3.],
       [0.,  2.,  0.],
       [1.,  0.,  0.]])
```

```
>>> rng = np.random.default_rng()
>>> A = rng.normal(size=(2,3,5))
>>> np.all(np.flipud(A) == A[::-1,...])
True
```

```
>>> np.flipud([1,2])
array([2, 1])
```

`numpy.roll(a, shift, axis=None)`

Roll array elements along a given axis.

Elements that roll beyond the last position are re-introduced at the first.

Parameters

a

[array_like] Input array.

shift

[int or tuple of ints] The number of places by which elements are shifted. If a tuple, then *axis* must be a tuple of the same size, and each of the given axes is shifted by the corresponding number. If an int while *axis* is a tuple of ints, then the same value is used for all given axes.

axis

[int or tuple of ints, optional] Axis or axes along which elements are shifted. By default, the array is flattened before shifting, after which the original shape is restored.

Returns

res

[ndarray] Output array, with the same shape as *a*.

See also:

[*rollaxis*](#)

Roll the specified axis backwards, until it lies in a given position.

Notes

Supports rolling over multiple dimensions simultaneously.

Examples

```
>>> import numpy as np
>>> x = np.arange(10)
>>> np.roll(x, 2)
array([8, 9, 0, 1, 2, 3, 4, 5, 6, 7])
>>> np.roll(x, -2)
array([2, 3, 4, 5, 6, 7, 8, 9, 0, 1])
```

```
>>> x2 = np.reshape(x, (2, 5))
>>> x2
array([[0, 1, 2, 3, 4],
       [5, 6, 7, 8, 9]])
>>> np.roll(x2, 1)
array([[9, 0, 1, 2, 3],
       [4, 5, 6, 7, 8]])
>>> np.roll(x2, -1)
array([[1, 2, 3, 4, 5],
       [6, 7, 8, 9, 0]])
>>> np.roll(x2, 1, axis=0)
array([[5, 6, 7, 8, 9],
       [0, 1, 2, 3, 4]])
>>> np.roll(x2, -1, axis=0)
array([[5, 6, 7, 8, 9],
       [0, 1, 2, 3, 4]])
>>> np.roll(x2, 1, axis=1)
array([[4, 0, 1, 2, 3],
       [9, 5, 6, 7, 8]])
>>> np.roll(x2, -1, axis=1)
array([[1, 2, 3, 4, 0],
       [6, 7, 8, 9, 5]])
>>> np.roll(x2, (1, 1), axis=(1, 0))
array([[9, 5, 6, 7, 8],
       [4, 0, 1, 2, 3]])
>>> np.roll(x2, (2, 1), axis=(1, 0))
array([[8, 9, 5, 6, 7],
       [3, 4, 0, 1, 2]])
```

`numpy.rot90(m, k=1, axes=(0, 1))`

Rotate an array by 90 degrees in the plane specified by axes.

Rotation direction is from the first towards the second axis. This means for a 2D array with the default *k* and *axes*, the rotation will be counterclockwise.

Parameters

m

[array_like] Array of two or more dimensions.

k

[integer] Number of times the array is rotated by 90 degrees.

axes

[(2,) array_like] The array is rotated in the plane defined by the axes. Axes must be different.

Returns

y
[ndarray] A rotated view of *m*.

See also:*flip*

Reverse the order of elements in an array along the given axis.

fliplr

Flip an array horizontally.

flipud

Flip an array vertically.

Notes

`rot90(m, k=1, axes=(1,0))` is the reverse of `rot90(m, k=1, axes=(0,1))`

`rot90(m, k=1, axes=(1,0))` is equivalent to `rot90(m, k=-1, axes=(0,1))`

Examples

```
>>> import numpy as np
>>> m = np.array([[1,2],[3,4]], int)
>>> m
array([[1, 2],
       [3, 4]])
>>> np.rot90(m)
array([[2, 4],
       [1, 3]])
>>> np.rot90(m, 2)
array([[4, 3],
       [2, 1]])
>>> m = np.arange(8).reshape((2,2,2))
>>> np.rot90(m, 1, (1,2))
array([[[1, 3],
        [0, 2]],
       [[5, 7],
        [4, 6]]])
```

1.4.4 Bit-wise operations

Elementwise bit operations

<code>bitwise_and(x1, x2, /[, out, where, ...])</code>	Compute the bit-wise AND of two arrays element-wise.
<code>bitwise_or(x1, x2, /[, out, where, casting, ...])</code>	Compute the bit-wise OR of two arrays element-wise.
<code>bitwise_xor(x1, x2, /[, out, where, ...])</code>	Compute the bit-wise XOR of two arrays element-wise.
<code>invert(x, /[, out, where, casting, order, ...])</code>	Compute bit-wise inversion, or bit-wise NOT, element-wise.
<code>bitwise_invert(x, /[, out, where, casting, ...])</code>	Compute bit-wise inversion, or bit-wise NOT, element-wise.
<code>left_shift(x1, x2, /[, out, where, casting, ...])</code>	Shift the bits of an integer to the left.
<code>bitwise_left_shift(x1, x2, /[, out, where, ...])</code>	Shift the bits of an integer to the left.
<code>right_shift(x1, x2, /[, out, where, ...])</code>	Shift the bits of an integer to the right.
<code>bitwise_right_shift(x1, x2, /[, out, where, ...])</code>	Shift the bits of an integer to the right.
<code>bitwise_count(x, /[, out, where, casting, ...])</code>	Computes the number of 1-bits in the absolute value of <code>x</code> .

```
numpy.bitwise_and(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None,
                  subok=True[, signature]) = <ufunc 'bitwise_and'>
```

Compute the bit-wise AND of two arrays element-wise.

Computes the bit-wise AND of the underlying binary representation of the integers in the input arrays. This ufunc implements the C/Python operator `&`.

Parameters**x1, x2**

[array_like] Only integer and boolean types are handled. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**out**

[ndarray or scalar] Result. This is a scalar if both `x1` and `x2` are scalars.

See also:

[logical_and](#)
[bitwise_or](#)
[bitwise_xor](#)
[binary_repr](#)

Return the binary representation of the input number as a string.

Examples

```
>>> import numpy as np
```

The number 13 is represented by 00001101. Likewise, 17 is represented by 00010001. The bit-wise AND of 13 and 17 is therefore 00000001, or 1:

```
>>> np.bitwise_and(13, 17)
1
```

```
>>> np.bitwise_and(14, 13)
12
>>> np.binary_repr(12)
'1100'
>>> np.bitwise_and([14, 3], 13)
array([12,  1])
```

```
>>> np.bitwise_and([11, 7], [4, 25])
array([0, 1])
>>> np.bitwise_and(np.array([2, 5, 255]), np.array([3, 14, 16]))
array([ 2,  4, 16])
>>> np.bitwise_and([True, True], [False, True])
array([False,  True])
```

The `&` operator can be used as a shorthand for `np.bitwise_and` on ndarrays.

```
>>> x1 = np.array([2, 5, 255])
>>> x2 = np.array([3, 14, 16])
>>> x1 & x2
array([ 2,  4, 16])
```

```
numpy.bitwise_or(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None,
                  subok=True[, signature]) = <ufunc 'bitwise_or'>
```

Compute the bit-wise OR of two arrays element-wise.

Computes the bit-wise OR of the underlying binary representation of the integers in the input arrays. This ufunc implements the C/Python operator `|`.

Parameters

x1, x2

[array_like] Only integer and boolean types are handled. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns**out**[ndarray or scalar] Result. This is a scalar if both *x1* and *x2* are scalars.**See also:**

logical_or
bitwise_and
bitwise_xor
binary_repr

Return the binary representation of the input number as a string.

Examples

```
>>> import numpy as np
```

The number 13 has the binary representation 00001101. Likewise, 16 is represented by 00010000. The bitwise OR of 13 and 16 is then 00011101, or 29:

```
>>> np.bitwise_or(13, 16)
29
>>> np.binary_repr(29)
'11101'
```

```
>>> np.bitwise_or(32, 2)
34
>>> np.bitwise_or([33, 4], 1)
array([33,  5])
>>> np.bitwise_or([33, 4], [1, 2])
array([33,  6])
```

```
>>> np.bitwise_or(np.array([2, 5, 255]), np.array([4, 4, 4]))
array([ 6,  5, 255])
>>> np.array([2, 5, 255]) | np.array([4, 4, 4])
array([ 6,  5, 255])
>>> np.bitwise_or(np.array([2, 5, 255, 2147483647], dtype=np.int32),
...               np.array([4, 4, 4, 2147483647], dtype=np.int32))
array([ 6,  5, 255, 2147483647], dtype=int32)
>>> np.bitwise_or([True, True], [False, True])
array([ True,  True])
```

The `|` operator can be used as a shorthand for `np.bitwise_or` on ndarrays.

```
>>> x1 = np.array([2, 5, 255])
>>> x2 = np.array([4, 4, 4])
>>> x1 | x2
array([ 6,  5, 255])
```

`numpy.bitwise_xor` (*x1*, *x2*, */*, *out=None*, ***, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True*, *signature*) = <ufunc 'bitwise_xor'>

Compute the bit-wise XOR of two arrays element-wise.

Computes the bit-wise XOR of the underlying binary representation of the integers in the input arrays. This ufunc implements the C/Python operator `^`.

Parameters

x1, x2

[array_like] Only integer and boolean types are handled. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**out**

[ndarray or scalar] Result. This is a scalar if both *x1* and *x2* are scalars.

See also:

[logical_xor](#)
[bitwise_and](#)
[bitwise_or](#)
[binary_repr](#)

Return the binary representation of the input number as a string.

Examples

```
>>> import numpy as np
```

The number 13 is represented by 00001101. Likewise, 17 is represented by 00010001. The bit-wise XOR of 13 and 17 is therefore 00011100, or 28:

```
>>> np.bitwise_xor(13, 17)
28
>>> np.binary_repr(28)
'11100'
```

```
>>> np.bitwise_xor(31, 5)
26
>>> np.bitwise_xor([31, 3], 5)
array([26,  6])
```

```
>>> np.bitwise_xor([31, 3], [5, 6])
array([26,  5])
>>> np.bitwise_xor([True, True], [False, True])
array([ True, False])
```

The `^` operator can be used as a shorthand for `np.bitwise_xor` on ndarrays.

```
>>> x1 = np.array([True, True])
>>> x2 = np.array([False, True])
>>> x1 ^ x2
array([ True, False])
```

`numpy.invert(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'invert'>`

Compute bit-wise inversion, or bit-wise NOT, element-wise.

Computes the bit-wise NOT of the underlying binary representation of the integers in the input arrays. This ufunc implements the C/Python operator `~`.

For signed integer inputs, the bit-wise NOT of the absolute value is returned. In a two's-complement system, this operation effectively flips all the bits, resulting in a representation that corresponds to the negative of the input plus one. This is the most common method of representing signed integers on computers [1]. An N -bit two's-complement system can represent every integer in the range -2^{N-1} to $+2^{N-1} - 1$.

Parameters

x

[array_like] Only integer and boolean types are handled.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Result. This is a scalar if *x* is a scalar.

See also:

[bitwise_and](#), [bitwise_or](#), [bitwise_xor](#)
[logical_not](#)
[binary_repr](#)

Return the binary representation of the input number as a string.

Notes

`numpy.bitwise_not` is an alias for `invert`:

```
>>> np.bitwise_not is np.invert
True
```

References

[1]

Examples

```
>>> import numpy as np
```

We've seen that 13 is represented by 00001101. The invert or bit-wise NOT of 13 is then:

```
>>> x = np.invert(np.array(13, dtype=np.uint8))
>>> x
np.uint8(242)
>>> np.binary_repr(x, width=8)
'11110010'
```

The result depends on the bit-width:

```
>>> x = np.invert(np.array(13, dtype=np.uint16))
>>> x
np.uint16(65522)
>>> np.binary_repr(x, width=16)
'11111111111110010'
```

When using signed integer types, the result is the bit-wise NOT of the unsigned type, interpreted as a signed integer:

```
>>> np.invert(np.array([13], dtype=np.int8))
array([-14], dtype=int8)
>>> np.binary_repr(-14, width=8)
'11110010'
```

Booleans are accepted as well:

```
>>> np.invert(np.array([True, False]))
array([False,  True])
```

The `~` operator can be used as a shorthand for `np.invert` on ndarrays.

```
>>> x1 = np.array([True, False])
>>> ~x1
array([False,  True])
```

`numpy.bitwise_invert` (*x*, */*, *out=None*, ***, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True*, *signature*) = **<ufunc 'invert'>**

Compute bit-wise inversion, or bit-wise NOT, element-wise.

Computes the bit-wise NOT of the underlying binary representation of the integers in the input arrays. This ufunc implements the C/Python operator `~`.

For signed integer inputs, the bit-wise NOT of the absolute value is returned. In a two's-complement system, this operation effectively flips all the bits, resulting in a representation that corresponds to the negative of the input plus one. This is the most common method of representing signed integers on computers [1]. An N -bit two's-complement system can represent every integer in the range -2^{N-1} to $+2^{N-1} - 1$.

Parameters

x

[array_like] Only integer and boolean types are handled.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Result. This is a scalar if *x* is a scalar.

See also:

[bitwise_and](#), [bitwise_or](#), [bitwise_xor](#)
[logical_not](#)
[binary_repr](#)

Return the binary representation of the input number as a string.

Notes

`numpy.bitwise_not` is an alias for [invert](#):

```
>>> np.bitwise_not is np.invert
True
```

References

[1]

Examples

```
>>> import numpy as np
```

We've seen that 13 is represented by 00001101. The invert or bit-wise NOT of 13 is then:

```
>>> x = np.invert(np.array(13, dtype=np.uint8))
>>> x
np.uint8(242)
>>> np.binary_repr(x, width=8)
'11110010'
```

The result depends on the bit-width:

```
>>> x = np.invert(np.array(13, dtype=np.uint16))
>>> x
np.uint16(65522)
>>> np.binary_repr(x, width=16)
'1111111111110010'
```

When using signed integer types, the result is the bit-wise NOT of the unsigned type, interpreted as a signed integer:

```
>>> np.invert(np.array([13], dtype=np.int8))
array([-14], dtype=int8)
>>> np.binary_repr(-14, width=8)
'11110010'
```

Booleans are accepted as well:

```
>>> np.invert(np.array([True, False]))
array([False,  True])
```

The `~` operator can be used as a shorthand for `np.invert` on ndarrays.

```
>>> x1 = np.array([True, False])
>>> ~x1
array([False,  True])
```

`numpy.left_shift(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'left_shift'>`

Shift the bits of an integer to the left.

Bits are shifted to the left by appending `x2` 0s at the right of `x1`. Since the internal representation of numbers is in binary format, this operation is equivalent to multiplying `x1` by 2^{x2} .

Parameters

x1

[array_like of integer type] Input values.

x2

[array_like of integer type] Number of zeros to append to `x1`. Has to be non-negative. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None,

a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**out**

[array of integer type] Return *x1* with bits shifted *x2* times to the left. This is a scalar if both *x1* and *x2* are scalars.

See also:[*right_shift*](#)

Shift the bits of an integer to the right.

[*binary_repr*](#)

Return the binary representation of the input number as a string.

Examples

```
>>> import numpy as np
>>> np.binary_repr(5)
'101'
>>> np.left_shift(5, 2)
20
>>> np.binary_repr(20)
'10100'
```

```
>>> np.left_shift(5, [1, 2, 3])
array([10, 20, 40])
```

Note that the dtype of the second argument may change the dtype of the result and can lead to unexpected results in some cases (see Casting Rules):

```
>>> a = np.left_shift(np.uint8(255), np.int64(1)) # Expect 254
>>> print(a, type(a)) # Unexpected result due to upcasting
510 <class 'numpy.int64'>
>>> b = np.left_shift(np.uint8(255), np.uint8(1))
>>> print(b, type(b))
254 <class 'numpy.uint8'>
```

The << operator can be used as a shorthand for `np.left_shift` on ndarrays.

```
>>> x1 = 5
>>> x2 = np.array([1, 2, 3])
>>> x1 << x2
array([10, 20, 40])
```

`numpy.bitwise_left_shift` (*x1*, *x2*, /, *out=None*, *, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True*[, *signature*]) = <ufunc 'left_shift'>

Shift the bits of an integer to the left.

Bits are shifted to the left by appending *x2* 0s at the right of *x1*. Since the internal representation of numbers is in binary format, this operation is equivalent to multiplying *x1* by 2^{**x2} .

Parameters

x1

[array_like of integer type] Input values.

x2

[array_like of integer type] Number of zeros to append to *x1*. Has to be non-negative. If *x1.shape != x2.shape*, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[array of integer type] Return *x1* with bits shifted *x2* times to the left. This is a scalar if both *x1* and *x2* are scalars.

See also:

[*right_shift*](#)

Shift the bits of an integer to the right.

[*binary_repr*](#)

Return the binary representation of the input number as a string.

Examples

```
>>> import numpy as np
>>> np.binary_repr(5)
'101'
>>> np.left_shift(5, 2)
20
>>> np.binary_repr(20)
'10100'
```

```
>>> np.left_shift(5, [1, 2, 3])
array([10, 20, 40])
```

Note that the dtype of the second argument may change the dtype of the result and can lead to unexpected results in some cases (see Casting Rules):

```
>>> a = np.left_shift(np.uint8(255), np.int64(1)) # Expect 254
>>> print(a, type(a)) # Unexpected result due to upcasting
510 <class 'numpy.int64'>
>>> b = np.left_shift(np.uint8(255), np.uint8(1))
>>> print(b, type(b))
254 <class 'numpy.uint8'>
```

The `<<` operator can be used as a shorthand for `np.left_shift` on ndarrays.

```
>>> x1 = 5
>>> x2 = np.array([1, 2, 3])
>>> x1 << x2
array([10, 20, 40])
```

`numpy.right_shift(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'right_shift'>`

Shift the bits of an integer to the right.

Bits are shifted to the right `x2`. Because the internal representation of numbers is in binary format, this operation is equivalent to dividing `x1` by 2^{*x2} .

Parameters

x1

[array_like, int] Input values.

x2

[array_like, int] Number of bits to remove at the right of `x1`. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray, int] Return `x1` with bits shifted `x2` times to the right. This is a scalar if both `x1` and `x2` are scalars.

See also:

[`left\_shift`](#)

Shift the bits of an integer to the left.

binary_repr

Return the binary representation of the input number as a string.

Examples

```
>>> import numpy as np
>>> np.binary_repr(10)
'1010'
>>> np.right_shift(10, 1)
5
>>> np.binary_repr(5)
'101'
```

```
>>> np.right_shift(10, [1,2,3])
array([5, 2, 1])
```

The `>>` operator can be used as a shorthand for `np.right_shift` on ndarrays.

```
>>> x1 = 10
>>> x2 = np.array([1,2,3])
>>> x1 >> x2
array([5, 2, 1])
```

`numpy.bitwise_right_shift` (*x1*, *x2*, */*, *out=None*, ***, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True*, *signature*) = `<ufunc 'right_shift'>`

Shift the bits of an integer to the right.

Bits are shifted to the right *x2*. Because the internal representation of numbers is in binary format, this operation is equivalent to dividing *x1* by 2^{**x2} .

Parameters***x1***

[array_like, int] Input values.

x2

[array_like, int] Number of bits to remove at the right of *x1*. If *x1.shape* != *x2.shape*, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

*****kwargs***

For other keyword-only arguments, see the *ufunc docs*.

Returns

out

[ndarray, int] Return *x1* with bits shifted *x2* times to the right. This is a scalar if both *x1* and *x2* are scalars.

See also:

[*left_shift*](#)

Shift the bits of an integer to the left.

[*binary_repr*](#)

Return the binary representation of the input number as a string.

Examples

```
>>> import numpy as np
>>> np.binary_repr(10)
'1010'
>>> np.right_shift(10, 1)
5
>>> np.binary_repr(5)
'101'
```

```
>>> np.right_shift(10, [1,2,3])
array([5, 2, 1])
```

The `>>` operator can be used as a shorthand for `np.right_shift` on ndarrays.

```
>>> x1 = 10
>>> x2 = np.array([1,2,3])
>>> x1 >> x2
array([5, 2, 1])
```

`numpy.bitwise_count` (*x*, */*, *out=None*, ***, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True*, *signature*) = `<ufunc 'bitwise_count'>`

Computes the number of 1-bits in the absolute value of *x*. Analogous to the builtin *int.bit_count* or *popcount* in C++.

Parameters

x

[array_like, unsigned int] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [*ufunc docs*](#).

Returns

y

[ndarray] The corresponding number of 1-bits in the input. Returns uint8 for all integer types
This is a scalar if *x* is a scalar.

References

[1], [2], [3]

Examples

```
>>> import numpy as np
>>> np.bitwise_count(1023)
np.uint8(10)
>>> a = np.array([2**i - 1 for i in range(16)])
>>> np.bitwise_count(a)
array([ 0,  1,  2,  3,  4,  5,  6,  7,  8,  9, 10, 11, 12, 13, 14, 15],
      dtype=uint8)
```

Bit packing

<code>packbits(a, /[, axis, bitorder])</code>	Packs the elements of a binary-valued array into bits in a uint8 array.
<code>unpackbits(a, /[, axis, count, bitorder])</code>	Unpacks elements of a uint8 array into a binary-valued output array.

`numpy.packbits(a, /[, axis=None, bitorder='big'])`

Packs the elements of a binary-valued array into bits in a uint8 array.

The result is padded to full bytes by inserting zero bits at the end.

Parameters

a

[array_like] An array of integers or booleans whose elements should be packed to bits.

axis

[int, optional] The dimension over which bit-packing is done. *None* implies packing the flattened array.

bitorder

[{'big', 'little'}, optional] The order of the input bits. 'big' will mimic `bin(val)`, `[0, 0, 0, 0, 0, 1, 1] => 3 = 0b00000011`, 'little' will reverse the order so `[1, 1, 0, 0, 0, 0, 0] => 3`. Defaults to 'big'.

Returns

packed

[ndarray] Array of type uint8 whose elements represent bits corresponding to the logical (0 or nonzero) value of the input elements. The shape of *packed* has the same number of dimensions as the input (unless *axis* is *None*, in which case the output is 1-D).

See also:

unpackbits

Unpacks elements of a uint8 array into a binary-valued output array.

Examples

```
>>> import numpy as np
>>> a = np.array([[1,0,1],
...               [0,1,0]],
...               [[1,1,0],
...               [0,0,1]])
>>> b = np.packbits(a, axis=-1)
>>> b
array([[160],
       [ 64]],
       [[192],
       [ 32]]], dtype=uint8)
```

Note that in binary 160 = 1010 0000, 64 = 0100 0000, 192 = 1100 0000, and 32 = 0010 0000.

`numpy.unpackbits(a, /, axis=None, count=None, bitorder='big')`

Unpacks elements of a uint8 array into a binary-valued output array.

Each element of *a* represents a bit-field that should be unpacked into a binary-valued output array. The shape of the output array is either 1-D (if *axis* is *None*) or the same shape as the input array with unpacking done along the axis specified.

Parameters

a

[ndarray, uint8 type] Input array.

axis

[int, optional] The dimension over which bit-unpacking is done. *None* implies unpacking the flattened array.

count

[int or *None*, optional] The number of elements to unpack along *axis*, provided as a way of undoing the effect of packing a size that is not a multiple of eight. A non-negative number means to only unpack *count* bits. A negative number means to trim off that many bits from the end. *None* means to unpack the entire array (the default). Counts larger than the available number of bits will add zero padding to the output. Negative counts must not exceed the available number of bits.

bitorder

[{'big', 'little'}, optional] The order of the returned bits. 'big' will mimic `bin(val)`, `3 = 0b000000011 => [0, 0, 0, 0, 0, 0, 1, 1]`, 'little' will reverse the order to `[1, 1, 0, 0, 0, 0, 0, 0]`. Defaults to 'big'.

Returns

unpacked

[ndarray, uint8 type] The elements are binary-valued (0 or 1).

See also:

packbits

Packs the elements of a binary-valued array into bits in a uint8 array.

Examples

```
>>> import numpy as np
>>> a = np.array([[2], [7], [23]], dtype=np.uint8)
>>> a
array([[ 2],
       [ 7],
       [23]], dtype=uint8)
>>> b = np.unpackbits(a, axis=1)
>>> b
array([[0, 0, 0, 0, 0, 0, 1, 0],
       [0, 0, 0, 0, 0, 1, 1, 1],
       [0, 0, 0, 1, 0, 1, 1, 1]], dtype=uint8)
>>> c = np.unpackbits(a, axis=1, count=-3)
>>> c
array([[0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0],
       [0, 0, 0, 1, 0]], dtype=uint8)
```

```
>>> p = np.packbits(b, axis=0)
>>> np.unpackbits(p, axis=0)
array([[0, 0, 0, 0, 0, 0, 1, 0],
       [0, 0, 0, 0, 0, 1, 1, 1],
       [0, 0, 0, 1, 0, 1, 1, 1],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0],
       [0, 0, 0, 0, 0, 0, 0, 0]], dtype=uint8)
>>> np.array_equal(b, np.unpackbits(p, axis=0, count=b.shape[0]))
True
```

Output formatting

`binary_repr(num[, width])`

Return the binary representation of the input number as a string.

`numpy.binary_repr(num, width=None)`

Return the binary representation of the input number as a string.

For negative numbers, if width is not given, a minus sign is added to the front. If width is given, the two's complement of the number is returned, with respect to that width.

In a two's-complement system negative numbers are represented by the two's complement of the absolute value. This is the most common method of representing signed integers on computers [1]. An N-bit two's-complement system can represent every integer in the range -2^{N-1} to $+2^{N-1} - 1$.

Parameters

num

[int] Only an integer decimal number can be used.

width

[int, optional] The length of the returned string if *num* is positive, or the length of the two's complement if *num* is negative, provided that *width* is at least a sufficient number of bits for

num to be represented in the designated form. If the *width* value is insufficient, an error is raised.

Returns

bin

[str] Binary representation of *num* or two's complement of *num*.

See also:

base_repr

Return a string representation of a number in the given base system.

bin

Python's built-in binary representation generator of an integer.

Notes

binary_repr is equivalent to using *base_repr* with base 2, but about 25x faster.

References

[1]

Examples

```
>>> import numpy as np
>>> np.binary_repr(3)
'11'
>>> np.binary_repr(-3)
'-11'
>>> np.binary_repr(3, width=4)
'0011'
```

The two's complement is returned when the input number is negative and width is specified:

```
>>> np.binary_repr(-3, width=3)
'101'
>>> np.binary_repr(-3, width=5)
'11101'
```

1.4.5 Datetime support functions

<i>datetime_as_string</i> (arr[, unit, timezone, ...])	Convert an array of datetimes into an array of strings.
<i>datetime_data</i> (dtype, /)	Get information about the step size of a date or time type.

`numpy.datetime_as_string(arr, unit=None, timezone='naive', casting='same_kind')`

Convert an array of datetimes into an array of strings.

Parameters

arr

[array_like of datetime64] The array of UTC timestamps to format.

unit

[str] One of None, 'auto', or a *datetime unit*.

timezone

[{'naive', 'UTC', 'local'} or tzinfo] Timezone information to use when displaying the datetime. If 'UTC', end with a Z to indicate UTC time. If 'local', convert to the local timezone first, and suffix with a +#### timezone offset. If a tzinfo object, then do as with 'local', but use the specified timezone.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}] Casting to allow when changing between datetime units.

Returns**str_arr**

[ndarray] An array of strings the same shape as *arr*.

Examples

```
>>> import numpy as np
>>> from zoneinfo import ZoneInfo
>>> d = np.arange('2002-10-27T04:30', 4*60, 60, dtype='M8[m]')
>>> d
array(['2002-10-27T04:30', '2002-10-27T05:30', '2002-10-27T06:30',
       '2002-10-27T07:30'], dtype='datetime64[m]')
```

Setting the timezone to UTC shows the same information, but with a Z suffix

```
>>> np.datetime_as_string(d, timezone='UTC')
array(['2002-10-27T04:30Z', '2002-10-27T05:30Z', '2002-10-27T06:30Z',
       '2002-10-27T07:30Z'], dtype='<U35')
```

Note that we picked datetimes that cross a DST boundary. Passing in a `ZoneInfo` object will print the appropriate offset

```
>>> np.datetime_as_string(d, timezone=ZoneInfo('US/Eastern'))
array(['2002-10-27T00:30-0400', '2002-10-27T01:30-0400',
       '2002-10-27T01:30-0500', '2002-10-27T02:30-0500'], dtype='<U39')
```

Passing in a unit will change the precision

```
>>> np.datetime_as_string(d, unit='h')
array(['2002-10-27T04', '2002-10-27T05', '2002-10-27T06', '2002-10-27T07'],
      dtype='<U32')
>>> np.datetime_as_string(d, unit='s')
array(['2002-10-27T04:30:00', '2002-10-27T05:30:00', '2002-10-27T06:30:00',
       '2002-10-27T07:30:00'], dtype='<U38')
```

'casting' can be used to specify whether precision can be changed

```
>>> np.datetime_as_string(d, unit='h', casting='safe')
Traceback (most recent call last):
...
```

(continues on next page)

(continued from previous page)

```
TypeError: Cannot create a datetime string as units 'h' from a NumPy
datetime with units 'm' according to the rule 'safe'
```

`numpy.datetime_data(dtype, /)`

Get information about the step size of a date or time type.

The returned tuple can be passed as the second argument of `numpy.datetime64` and `numpy.timedelta64`.

Parameters

`dtype`

[dtype] The dtype object, which must be a `datetime64` or `timedelta64` type.

Returns

`unit`

[str] The *datetime unit* on which this dtype is based.

`count`

[int] The number of base units in a step.

Examples

```
>>> import numpy as np
>>> dt_25s = np.dtype('timedelta64[25s]')
>>> np.datetime_data(dt_25s)
('s', 25)
>>> np.array(10, dt_25s).astype('timedelta64[s]')
array(250, dtype='timedelta64[s]')
```

The result can be used to construct a datetime that uses the same units as a timedelta

```
>>> np.datetime64('2010', np.datetime_data(dt_25s))
np.datetime64('2010-01-01T00:00:00', '25s')
```

Business day functions

<code>busdaycalendar([weekmask, holidays])</code>	A business day calendar object that efficiently stores information defining valid days for the busday family of functions.
<code>is_busday(dates[, weekmask, holidays, ...])</code>	Calculates which of the given dates are valid days, and which are not.
<code>busday_offset(dates, offsets[, roll, ...])</code>	First adjusts the date to fall on a valid day according to the <code>roll</code> rule, then applies offsets to the given dates counted in valid days.
<code>busday_count(begindates, enddates[, ...])</code>	Counts the number of valid days between <i>begindates</i> and <i>enddate</i> s, not including the day of <i>enddate</i> s.

class `numpy.busdaycalendar(weekmask='1111100', holidays=None)`

A business day calendar object that efficiently stores information defining valid days for the busday family of functions.

The default valid days are Monday through Friday (“business days”). A `busdaycalendar` object can be specified with any set of weekly valid days, plus an optional “holiday” dates that always will be invalid.

Once a `busdaycalendar` object is created, the `weekmask` and holidays cannot be modified.

Parameters

weekmask

[str or array_like of bool, optional] A seven-element array indicating which of Monday through Sunday are valid days. May be specified as a length-seven list or array, like `[1,1,1,1,1,0,0]`; a length-seven string, like `'1111100'`; or a string like `“Mon Tue Wed Thu Fri”`, made up of 3-character abbreviations for weekdays, optionally separated by white space. Valid abbreviations are: Mon Tue Wed Thu Fri Sat Sun

holidays

[array_like of datetime64[D], optional] An array of dates to consider as invalid dates, no matter which weekday they fall upon. Holiday dates may be specified in any order, and NaT (not-a-time) dates are ignored. This list is saved in a normalized form that is suited for fast calculations of valid days.

Attributes

weekmask

[(copy) seven-element array of bool] A copy of the seven-element boolean mask indicating valid days.

holidays

[(copy) sorted array of datetime64[D]] A copy of the holiday array indicating additional invalid days.

Returns

out

[`busdaycalendar`] A business day calendar object containing the specified `weekmask` and `holidays` values.

See also:

is_busday

Returns a boolean array indicating valid days.

busday_offset

Applies an offset counted in valid days.

busday_count

Counts how many valid days are in a half-open date range.

Notes

Once a `busdaycalendar` object is created, you cannot modify the `weekmask` or `holidays`. The attributes return copies of internal data.

Examples

```
>>> import numpy as np
>>> # Some important days in July
... bdd = np.busdaycalendar(
...     holidays=['2011-07-01', '2011-07-04', '2011-07-17'])
>>> # Default is Monday to Friday weekdays
... bdd.weekmask
array([ True,  True,  True,  True,  True, False, False])
>>> # Any holidays already on the weekend are removed
... bdd.holidays
array(['2011-07-01', '2011-07-04'], dtype='datetime64[D]')
```

`numpy.is_busday` (*dates*, *weekmask*='1111100', *holidays*=None, *busdaycal*=None, *out*=None)

Calculates which of the given dates are valid days, and which are not.

Parameters

dates

[array_like of datetime64[D]] The array of dates to process.

weekmask

[str or array_like of bool, optional] A seven-element array indicating which of Monday through Sunday are valid days. May be specified as a length-seven list or array, like [1,1,1,1,1,0,0]; a length-seven string, like '1111100'; or a string like "Mon Tue Wed Thu Fri", made up of 3-character abbreviations for weekdays, optionally separated by white space. Valid abbreviations are: Mon Tue Wed Thu Fri Sat Sun

holidays

[array_like of datetime64[D], optional] An array of dates to consider as invalid dates. They may be specified in any order, and NaT (not-a-time) dates are ignored. This list is saved in a normalized form that is suited for fast calculations of valid days.

busdaycal

[busdaycalendar, optional] A *busdaycalendar* object which specifies the valid days. If this parameter is provided, neither weekmask nor holidays may be provided.

out

[array of bool, optional] If provided, this array is filled with the result.

Returns

out

[array of bool] An array with the same shape as *dates*, containing True for each valid day, and False for each invalid day.

See also:

busdaycalendar

An object that specifies a custom set of valid days.

busday_offset

Applies an offset counted in valid days.

busday_count

Counts how many valid days are in a half-open date range.

Examples

```
>>> import numpy as np
>>> # The weekdays are Friday, Saturday, and Monday
... np.is_busday(['2011-07-01', '2011-07-02', '2011-07-18'],
...              holidays=['2011-07-01', '2011-07-04', '2011-07-17'])
array([False, False,  True])
```

`numpy.busday_offset` (*dates*, *offsets*, *roll*='raise', *weekmask*='1111100', *holidays*=None, *busdaycal*=None, *out*=None)

First adjusts the date to fall on a valid day according to the `roll` rule, then applies offsets to the given dates counted in valid days.

Parameters

dates

[array_like of datetime64[D]] The array of dates to process.

offsets

[array_like of int] The array of offsets, which is broadcast with *dates*.

roll

[{'raise', 'nat', 'forward', 'following', 'backward', 'preceding', 'modifiedfollowing', 'modifiedpreceding'}, optional] How to treat dates that do not fall on a valid day. The default is 'raise'.

- 'raise' means to raise an exception for an invalid day.
- 'nat' means to return a NaT (not-a-time) for an invalid day.
- 'forward' and 'following' mean to take the first valid day later in time.
- 'backward' and 'preceding' mean to take the first valid day earlier in time.
- 'modifiedfollowing' means to take the first valid day later in time unless it is across a Month boundary, in which case to take the first valid day earlier in time.
- 'modifiedpreceding' means to take the first valid day earlier in time unless it is across a Month boundary, in which case to take the first valid day later in time.

weekmask

[str or array_like of bool, optional] A seven-element array indicating which of Monday through Sunday are valid days. May be specified as a length-seven list or array, like [1,1,1,1,1,0,0]; a length-seven string, like '1111100'; or a string like "Mon Tue Wed Thu Fri", made up of 3-character abbreviations for weekdays, optionally separated by white space. Valid abbreviations are: Mon Tue Wed Thu Fri Sat Sun

holidays

[array_like of datetime64[D], optional] An array of dates to consider as invalid dates. They may be specified in any order, and NaT (not-a-time) dates are ignored. This list is saved in a normalized form that is suited for fast calculations of valid days.

busdaycal

[busdaycalendar, optional] A *busdaycalendar* object which specifies the valid days. If this parameter is provided, neither *weekmask* nor *holidays* may be provided.

out

[array of datetime64[D], optional] If provided, this array is filled with the result.

Returns

out

[array of datetime64[D]] An array with a shape from broadcasting dates and offsets together, containing the dates with offsets applied.

See also:

busdaycalendar

An object that specifies a custom set of valid days.

is_busday

Returns a boolean array indicating valid days.

busday_count

Counts how many valid days are in a half-open date range.

Examples

```
>>> import numpy as np
>>> # First business day in October 2011 (not accounting for holidays)
... np.busday_offset('2011-10', 0, roll='forward')
np.datetime64('2011-10-03')
>>> # Last business day in February 2012 (not accounting for holidays)
... np.busday_offset('2012-03', -1, roll='forward')
np.datetime64('2012-02-29')
>>> # Third Wednesday in January 2011
... np.busday_offset('2011-01', 2, roll='forward', weekmask='Wed')
np.datetime64('2011-01-19')
>>> # 2012 Mother's Day in Canada and the U.S.
... np.busday_offset('2012-05', 1, roll='forward', weekmask='Sun')
np.datetime64('2012-05-13')
```

```
>>> # First business day on or after a date
... np.busday_offset('2011-03-20', 0, roll='forward')
np.datetime64('2011-03-21')
>>> np.busday_offset('2011-03-22', 0, roll='forward')
np.datetime64('2011-03-22')
>>> # First business day after a date
... np.busday_offset('2011-03-20', 1, roll='backward')
np.datetime64('2011-03-21')
>>> np.busday_offset('2011-03-22', 1, roll='backward')
np.datetime64('2011-03-23')
```

`numpy.busday_count` (*begindates*, *enddates*, *weekmask*='1111100', *holidays*=[], *busdaycal*=None, *out*=None)

Counts the number of valid days between *begindates* and *enddates*, not including the day of *enddates*.

If *enddates* specifies a date value that is earlier than the corresponding *begindates* date value, the count will be negative.

Parameters

begindates

[array_like of datetime64[D]] The array of the first dates for counting.

enddates

[array_like of datetime64[D]] The array of the end dates for counting, which are excluded from the count themselves.

weekmask

[str or array_like of bool, optional] A seven-element array indicating which of Monday through Sunday are valid days. May be specified as a length-seven list or array, like [1,1,1,1,1,0,0]; a length-seven string, like '1111100'; or a string like "Mon Tue Wed Thu Fri", made up of 3-character abbreviations for weekdays, optionally separated by white space. Valid abbreviations are: Mon Tue Wed Thu Fri Sat Sun

holidays

[array_like of datetime64[D], optional] An array of dates to consider as invalid dates. They may be specified in any order, and NaT (not-a-time) dates are ignored. This list is saved in a normalized form that is suited for fast calculations of valid days.

busdaycal

[busdaycalendar, optional] A *busdaycalendar* object which specifies the valid days. If this parameter is provided, neither weekmask nor holidays may be provided.

out

[array of int, optional] If provided, this array is filled with the result.

Returns**out**

[array of int] An array with a shape from broadcasting *begindates* and *enddates* together, containing the number of valid days between the begin and end dates.

See also:*busdaycalendar*

An object that specifies a custom set of valid days.

is_busday

Returns a boolean array indicating valid days.

busday_offset

Applies an offset counted in valid days.

Examples

```
>>> import numpy as np
>>> # Number of weekdays in January 2011
... np.busday_count('2011-01', '2011-02')
21
>>> # Number of weekdays in 2011
>>> np.busday_count('2011', '2012')
260
>>> # Number of Saturdays in 2011
... np.busday_count('2011', '2012', weekmask='Sat')
53
```

1.4.6 Data type routines

<code>can_cast(from_, to[, casting])</code>	Returns True if cast between data types can occur according to the casting rule.
<code>promote_types(type1, type2, /)</code>	Returns the data type with the smallest size and smallest scalar kind to which both <code>type1</code> and <code>type2</code> may be safely cast.
<code>min_scalar_type(a, /)</code>	For scalar <code>a</code> , returns the data type with the smallest size and smallest scalar kind which can hold its value.
<code>result_type(*arrays_and_dtypes)</code>	Returns the type that results from applying the NumPy <i>type promotion</i> rules to the arguments.
<code>common_type(*arrays)</code>	Return a scalar type which is common to the input arrays.

`numpy.can_cast` (*from_*, *to*, *casting*='safe')

Returns True if cast between data types can occur according to the casting rule.

Parameters

from_

[dtype, dtype specifier, NumPy scalar, or array] Data type, NumPy scalar, or array to cast from.

to

[dtype or dtype specifier] Data type to cast to.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur.

- 'no' means the data types should not be cast at all.
- 'equiv' means only byte-order changes are allowed.
- 'safe' means only casts which can preserve values are allowed.
- 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed.
- 'unsafe' means any data conversions may be done.

Returns

out

[bool] True if cast can occur according to the casting rule.

See also:

`dtype`, `result_type`

Notes

Changed in version 2.0: This function does not support Python scalars anymore and does not apply any value-based logic for 0-D arrays and NumPy scalars.

Examples

Basic examples

```
>>> import numpy as np
>>> np.can_cast(np.int32, np.int64)
True
>>> np.can_cast(np.float64, complex)
True
>>> np.can_cast(complex, float)
False
```

```
>>> np.can_cast('i8', 'f8')
True
>>> np.can_cast('i8', 'f4')
False
>>> np.can_cast('i4', 'S4')
False
```

`numpy.promote_types(type1, type2, /)`

Returns the data type with the smallest size and smallest scalar kind to which both `type1` and `type2` may be safely cast. The returned data type is always considered “canonical”, this mainly means that the promoted dtype will always be in native byte order.

This function is symmetric, but rarely associative.

Parameters

type1

[dtype or dtype specifier] First data type.

type2

[dtype or dtype specifier] Second data type.

Returns

out

[dtype] The promoted data type.

See also:

[*result_type*](#), [*dtype*](#), [*can_cast*](#)

Notes

Please see `numpy.result_type` for additional information about promotion.

Starting in NumPy 1.9, `promote_types` function now returns a valid string length when given an integer or float dtype as one argument and a string dtype as another argument. Previously it always returned the input string dtype, even if it wasn't long enough to store the max integer/float value converted to a string.

Changed in version 1.23.0.

NumPy now supports promotion for more structured dtypes. It will now remove unnecessary padding from a structure dtype and promote included fields individually.

Examples

```
>>> import numpy as np
>>> np.promote_types(np.float32, np.float64)
dtype('float64')
```

```
>>> np.promote_types(np.int64, np.float32)
dtype('float64')
```

```
>>> np.promote_types('>i8', '<c8')
dtype('complex128')
```

```
>>> np.promote_types(np.int32, 'S8')
dtype('S11')
```

An example of a non-associative case:

```
>>> p = np.promote_types
>>> p('S', p('i1', 'u1'))
dtype('S6')
>>> p(p('S', 'i1'), 'u1')
dtype('S4')
```

`numpy.min_scalar_type(a, /)`

For scalar `a`, returns the data type with the smallest size and smallest scalar kind which can hold its value. For non-scalar array `a`, returns the vector's dtype unmodified.

Floating point values are not demoted to integers, and complex values are not demoted to floats.

Parameters

a
[scalar or array_like] The value whose minimal data type is to be found.

Returns

out
[dtype] The minimal data type.

See also:

[`result\_type`](#), [`promote\_types`](#), [`dtype`](#), [`can\_cast`](#)

Examples

```
>>> import numpy as np
>>> np.min_scalar_type(10)
dtype('uint8')
```

```
>>> np.min_scalar_type(-260)
dtype('int16')
```

```
>>> np.min_scalar_type(3.1)
dtype('float16')
```

```
>>> np.min_scalar_type(1e50)
dtype('float64')
```

```
>>> np.min_scalar_type(np.arange(4, dtype=np.float64))
dtype('float64')
```

`numpy.result_type(*arrays_and_dtypes)`

Returns the type that results from applying the NumPy *type promotion* rules to the arguments.

Parameters

`arrays_and_dtypes`

[list of arrays and dtypes] The operands of some operation whose result type is needed.

Returns

`out`

[dtype] The result type.

See also:

[*dtype*](#), [*promote_types*](#), [*min_scalar_type*](#), [*can_cast*](#)

Examples

```
>>> import numpy as np
>>> np.result_type(3, np.arange(7, dtype=np.int8))
dtype('int8')
```

```
>>> np.result_type(np.int32, np.complex64)
dtype('complex128')
```

```
>>> np.result_type(3.0, -2)
dtype('float64')
```

`numpy.common_type(*arrays)`

Return a scalar type which is common to the input arrays.

The return type will always be an inexact (i.e. floating point) scalar type, even if all the arrays are integer arrays. If one of the inputs is an integer array, the minimum precision type that is returned is a 64-bit floating point dtype.

All input arrays except `int64` and `uint64` can be safely cast to the returned dtype without loss of information.

Parameters

array1, array2, ...
[ndarrays] Input arrays.

Returns

out
[data type code] Data type code.

See also:

dtype, *mintypecode*

Examples

```
>>> np.common_type(np.arange(2, dtype=np.float32))
<class 'numpy.float32'>
>>> np.common_type(np.arange(2, dtype=np.float32), np.arange(2))
<class 'numpy.float64'>
>>> np.common_type(np.arange(4), np.array([45, 6.j]), np.array([45.0]))
<class 'numpy.complex128'>
```

Creating data types

dtype(dtype[, align, copy])

--

rec.format_parser(formats, names, titles[, ...])

Class to convert formats, names, titles description to a dtype.

Data type information

info(dtype)

Machine limits for floating point types.

iinfo(type)

Machine limits for integer types.

class `numpy.info`(dtype)

Machine limits for floating point types.

Parameters**dtype**

[float, dtype, or instance] Kind of floating point or complex floating point data-type about which to get information.

Attributes**bits**

[int] The number of bits occupied by the type.

dtype

[dtype] Returns the dtype for which *info* returns information. For complex input, the returned dtype is the associated `float*` dtype for its real and complex components.

eps

[float] The difference between 1.0 and the next smallest representable float larger than 1.0. For example, for 64-bit binary floats in the IEEE-754 standard, `eps = 2**-52`, approximately 2.22e-16.

epsneg

[float] The difference between 1.0 and the next smallest representable float less than 1.0. For example, for 64-bit binary floats in the IEEE-754 standard, `epsneg = 2**-53`, approximately 1.11e-16.

iexp

[int] The number of bits in the exponent portion of the floating point representation.

machep

[int] The exponent that yields `eps`.

max

[floating point number of the appropriate type] The largest representable number.

maxexp

[int] The smallest positive power of the base (2) that causes overflow. Corresponds to the C standard `MAX_EXP`.

min

[floating point number of the appropriate type] The smallest representable number, typically `-max`.

minexp

[int] The most negative power of the base (2) consistent with there being no leading 0's in the mantissa. Corresponds to the C standard `MIN_EXP - 1`.

negep

[int] The exponent that yields `epsneg`.

nexp

[int] The number of bits in the exponent including its sign and bias.

nmant

[int] The number of explicit bits in the mantissa (excluding the implicit leading bit for normalized numbers).

precision

[int] The approximate number of decimal digits to which this kind of float is precise.

resolution

[floating point number of the appropriate type] The approximate decimal resolution of this type, i.e., `10**-precision`.

tiny

[float] An alias for `smallest_normal`, kept for backwards compatibility.

smallest_normal

[float] The smallest positive floating point number with 1 as leading bit in the mantissa following IEEE-754 (see Notes).

smallest_subnormal

[float] The smallest positive floating point number with 0 as leading bit in the mantissa following IEEE-754.

See also:

info

The equivalent for integer data types.

spacing

The distance between a value and the nearest adjacent number

nextafter

The next floating point value after x1 towards x2

Notes

For developers of NumPy: do not instantiate this at the module level. The initial calculation of these parameters is expensive and negatively impacts import times. These objects are cached, so calling `finfo()` repeatedly inside your functions is not a problem.

Note that `smallest_normal` is not actually the smallest positive representable value in a NumPy floating point type. As in the IEEE-754 standard [1], NumPy floating point types make use of subnormal numbers to fill the gap between 0 and `smallest_normal`. However, subnormal numbers may have significantly reduced precision [2].

For `longdouble`, the representation varies across platforms. On most platforms it is IEEE 754 binary128 (quad precision) or binary64-extended (80-bit extended precision). On PowerPC systems, it may use the IBM double-double format (a pair of float64 values), which has special characteristics for precision and range.

This function can also be used for complex data types as well. If used, the output will be the same as the corresponding real float type (e.g. `numpy.finfo(numpy.csingle)` is the same as `numpy.finfo(numpy.single)`). However, the output is true for the real and imaginary components.

References

[1], [2]

Examples

```
>>> import numpy as np
>>> np.finfo(np.float64).dtype
dtype('float64')
>>> np.finfo(np.complex64).dtype
dtype('float32')
```

class `numpy.iinfo`(*type*)

Machine limits for integer types.

Parameters**`int_type`**

[integer type, dtype, or instance] The kind of integer data type to get information about.

Attributes**`bits`**

[int] The number of bits occupied by the type.

`dtype`

[dtype] Returns the dtype for which `info` returns information.

`min`

[int] Minimum value of given dtype.

max

[int] Maximum value of given dtype.

See also:

finfo

The equivalent for floating point data types.

Examples

With types:

```
>>> import numpy as np
>>> ii16 = np.iinfo(np.int16)
>>> ii16.min
-32768
>>> ii16.max
32767
>>> ii32 = np.iinfo(np.int32)
>>> ii32.min
-2147483648
>>> ii32.max
2147483647
```

With instances:

```
>>> ii32 = np.iinfo(np.int32(10))
>>> ii32.min
-2147483648
>>> ii32.max
2147483647
```

Data type testing

<code>isdtype(dtype, kind)</code>	Determine if a provided dtype is of a specified data type kind.
<code>issubdtype(arg1, arg2)</code>	Returns True if first argument is a typecode lower/equal in type hierarchy.

`numpy.isdtype(dtype, kind)`

Determine if a provided dtype is of a specified data type kind.

This function only supports built-in NumPy's data types. Third-party dtypes are not yet supported.

Parameters**dtype**

[dtype] The input dtype.

kind

[dtype or str or tuple of dtypes/strs.] dtype or dtype kind. Allowed dtype kinds are: * 'bool' : boolean kind * 'signed integer' : signed integer data types * 'unsigned integer' : unsigned integer data types * 'integral' : integer data types * 'real floating' : real-valued floating-point data types * 'complex floating' : complex floating-point data types * 'numeric' : numeric data types

Returns

out
[bool]

See also:

issubdtype

Examples

```
>>> import numpy as np
>>> np.issdtype(np.float32, np.float64)
False
>>> np.issdtype(np.float32, "real floating")
True
>>> np.issdtype(np.complex128, ("real floating", "complex floating"))
True
```

`numpy.issubdtype(arg1, arg2)`

Returns True if first argument is a typecode lower/equal in type hierarchy.

This is like the builtin `issubclass`, but for *dtypes*.

Parameters

arg1, arg2
[dtype_like] *dtype* or object coercible to one

Returns

out
[bool]

See also:

Scalars

Overview of the numpy type hierarchy.

Examples

issubdtype can be used to check the type of arrays:

```
>>> ints = np.array([1, 2, 3], dtype=np.int32)
>>> np.issubdtype(ints.dtype, np.integer)
True
>>> np.issubdtype(ints.dtype, np.floating)
False
```

```
>>> floats = np.array([1, 2, 3], dtype=np.float32)
>>> np.issubdtype(floats.dtype, np.integer)
False
>>> np.issubdtype(floats.dtype, np.floating)
True
```

Similar types of different sizes are not subtypes of each other:

```
>>> np.issubdtype(np.float64, np.float32)
False
>>> np.issubdtype(np.float32, np.float64)
False
```

but both are subtypes of *floating*:

```
>>> np.issubdtype(np.float64, np.floating)
True
>>> np.issubdtype(np.float32, np.floating)
True
```

For convenience, dtype-like objects are allowed too:

```
>>> np.issubdtype('S1', np.bytes_)
True
>>> np.issubdtype('i4', np.signedinteger)
True
```

Miscellaneous

<i>typename</i> (char)	Return a description for the given data type code.
<i>mintypecode</i> (typechars[, typeset, default])	Return the character for the minimum-size type to which given types can be safely cast.

`numpy.typename(char)`

Return a description for the given data type code.

Deprecated since version 2.5: `numpy.typename` is deprecated. Use `numpy.dtype.name` instead.

Parameters

char

[str] Data type code.

Returns

out

[str] Description of the input data type code.

See also:

dtype

Examples

```
>>> import numpy as np
>>> typechars = ['S1', '?', 'B', 'D', 'G', 'F', 'I', 'H', 'L', 'O', 'Q',
...             'S', 'U', 'V', 'b', 'd', 'g', 'f', 'i', 'h', 'l', 'q']
>>> for typechar in typechars:
...     print(typechar, ' : ', np.typename(typechar))
...
S1 : character
? : bool
```

(continues on next page)

(continued from previous page)

```
B : unsigned char
D : complex double precision
G : complex long double precision
F : complex single precision
I : unsigned integer
H : unsigned short
L : unsigned long integer
O : object
Q : unsigned long long integer
S : string
U : unicode
V : void
b : signed char
d : double precision
g : long precision
f : single precision
i : integer
h : short
l : long integer
q : long long integer
```

`numpy.mintypecode` (*typechars*, *typeset*='GDFgdf', *default*='d')

Return the character for the minimum-size type to which given types can be safely cast.

The returned type character must represent the smallest size dtype such that an array of the returned type can handle the data from an array of all types in *typechars* (or if *typechars* is an array, then its `dtype.char`).

Parameters

typechars

[list of str or array_like] If a list of strings, each string should represent a dtype. If array_like, the character representation of the array dtype is used.

typeset

[str or list of str, optional] The set of characters that the returned character is chosen from. The default set is 'GDFgdf'.

default

[str, optional] The default character, this is returned if none of the characters in *typechars* matches a character in *typeset*.

Returns

typechar

[str] The character representing the minimum-size type that was found.

See also:

[*dtype*](#)

Examples

```
>>> import numpy as np
>>> np.mintypecode(['d', 'f', 'S'])
'd'
>>> x = np.array([1.1, 2-3.j])
>>> np.mintypecode(x)
'D'
```

```
>>> np.mintypecode('abceh', default='G')
'G'
```

1.4.7 Floating point error handling

Error handling settings are stored in `contextvars` allowing different threads or async tasks to have independent configurations. For more information, see *Thread Safety*.

How numpy handles numerical exceptions

The default is to 'warn' for invalid, divide, and overflow and 'ignore' for underflow. But this can be changed, and it can be set individually for different kinds of exceptions. The different behaviors are:

- 'ignore' : Take no action when the exception occurs.
- 'warn' : Print a `RuntimeWarning` (via the Python `warnings` module).
- 'raise' : Raise a `FloatingPointError`.
- 'call' : Call a specified function.
- 'print' : Print a warning directly to `stdout`.
- 'log' : Record error in a Log object.

These behaviors can be set for all kinds of errors or specific ones:

- `all` : apply to all numeric exceptions
- `invalid` : when NaNs are generated
- `divide` : divide by zero (for integers as well!)
- `overflow` : floating point overflows
- `underflow` : floating point underflows

Note that integer divide-by-zero is handled by the same machinery.

The error handling mode can be configured `numpy.errstate` context manager.

Examples

```
>>> with np.errstate(all='warn'):
...     np.zeros(5, dtype=np.float32) / 0.0
<python-input-1>:2: RuntimeWarning: invalid value encountered in divide
array([nan, nan, nan, nan, nan], dtype=float32)
```

```
>>> with np.errstate(under='ignore'):
...     np.array([1.e-100])**10
array([0.])
```

```
>>> with np.errstate(invalid='raise'):
...     np.sqrt(np.array([-1.]))
...
Traceback (most recent call last):
  File "<python-input-1>", line 2, in <module>
    np.sqrt(np.array([-1.]))
    ~~~~~^~~~~~
FloatingPointError: invalid value encountered in sqrt
```

```
>>> def errorhandler(errstr, errflag):
...     print("saw stupid error!")
>>> with np.errstate(call=errorhandler, all='call'):
...     np.zeros(5, dtype=np.int32) / 0
saw stupid error!
array([nan, nan, nan, nan, nan])
```

Setting and getting error handling

<code>seterr([all, divide, over, under, invalid])</code>	Set how floating-point errors are handled.
<code>geterr()</code>	Get the current way of handling floating-point errors.
<code>seterrcall(func)</code>	Set the floating-point error callback function or log object.
<code>geterrcall()</code>	Return the current callback function used on floating-point errors.
<code>errstate(**kwargs)</code>	Context manager for floating-point error handling.

`numpy.seterr` (*all=None, divide=None, over=None, under=None, invalid=None*)

Set how floating-point errors are handled.

Note that operations on integer scalar types (such as `int16`) are handled like floating point, and are affected by these settings.

Parameters

`all`

[{'ignore', 'warn', 'raise', 'call', 'print', 'log'}, optional] Set treatment for all types of floating-point errors at once:

- `ignore`: Take no action when the exception occurs.
- `warn`: Print a `RuntimeWarning` (via the Python `warnings` module).
- `raise`: Raise a `FloatingPointError`.
- `call`: Call a function specified using the `seterrcall` function.

- `print`: Print a warning directly to `stdout`.
- `log`: Record error in a Log object specified by `seterrcall`.

The default is not to change the current behavior.

divide

[{'ignore', 'warn', 'raise', 'call', 'print', 'log'}, optional] Treatment for division by zero.

over

[{'ignore', 'warn', 'raise', 'call', 'print', 'log'}, optional] Treatment for floating-point overflow.

under

[{'ignore', 'warn', 'raise', 'call', 'print', 'log'}, optional] Treatment for floating-point underflow.

invalid

[{'ignore', 'warn', 'raise', 'call', 'print', 'log'}, optional] Treatment for invalid floating-point operation.

Returns

old_settings

[dict] Dictionary containing the old settings.

See also:

`seterrcall`

Set a callback function for the 'call' mode.

`geterr`, `geterrcall`, `errstate`

Notes

The floating-point exceptions are defined in the IEEE 754 standard [1]:

- Division by zero: infinite result obtained from finite numbers.
- Overflow: result too large to be expressed.
- Underflow: result so close to zero that some precision was lost.
- Invalid operation: result is not an expressible number, typically indicates that a NaN was produced.

Concurrency note: see *Floating point error handling*

Examples

```
>>> import numpy as np
>>> orig_settings = np.seterr(all='ignore') # seterr to known value
>>> np.int16(32000) * np.int16(3)
np.int16(30464)
>>> np.seterr(over='raise')
{'divide': 'ignore', 'over': 'ignore', 'under': 'ignore', 'invalid': 'ignore'}
>>> old_settings = np.seterr(all='warn', over='raise')
>>> np.int16(32000) * np.int16(3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
FloatingPointError: overflow encountered in scalar multiply
```

```

>>> old_settings = np.seterr(all='print')
>>> np.geterr()
{'divide': 'print', 'over': 'print', 'under': 'print', 'invalid': 'print'}
>>> np.int16(32000) * np.int16(3)
np.int16(30464)
>>> np.seterr(**orig_settings) # restore original
{'divide': 'print', 'over': 'print', 'under': 'print', 'invalid': 'print'}

```

`numpy.geterr()`

Get the current way of handling floating-point errors.

Returns

res

[dict] A dictionary with keys “divide”, “over”, “under”, and “invalid”, whose values are from the strings “ignore”, “print”, “log”, “warn”, “raise”, and “call”. The keys represent possible floating-point exceptions, and the values define how these exceptions are handled.

See also:

[`geterrcall`](#), [`seterr`](#), [`seterrcall`](#)

Notes

For complete documentation of the types of floating-point exceptions and treatment options, see [`seterr`](#).

Concurrency note: see [Floating point error handling](#)

Examples

```

>>> import numpy as np
>>> np.geterr()
{'divide': 'warn', 'over': 'warn', 'under': 'ignore', 'invalid': 'warn'}
>>> np.arange(3.) / np.arange(3.)
array([nan,  1.,  1.])
RuntimeWarning: invalid value encountered in divide

```

```

>>> oldsettings = np.seterr(all='warn', invalid='raise')
>>> np.geterr()
{'divide': 'warn', 'over': 'warn', 'under': 'warn', 'invalid': 'raise'}
>>> np.arange(3.) / np.arange(3.)
Traceback (most recent call last):
...
FloatingPointError: invalid value encountered in divide
>>> oldsettings = np.seterr(**oldsettings) # restore original

```

`numpy.seterrcall(func)`

Set the floating-point error callback function or log object.

There are two ways to capture floating-point error messages. The first is to set the error-handler to ‘call’, using [`seterr`](#). Then, set the function to call using this function.

The second is to set the error-handler to ‘log’, using [`seterr`](#). Floating-point errors then trigger a call to the ‘write’ method of the provided object.

Parameters

func

[callable f(err, flag) or object with write method] Function to call upon floating-point errors ('call'-mode) or object whose 'write' method is used to log such message ('log'-mode).

The call function takes two arguments. The first is a string describing the type of error (such as "divide by zero", "overflow", "underflow", or "invalid value"), and the second is the status flag. The flag is a byte, whose four least-significant bits indicate the type of error, one of "divide", "over", "under", "invalid":

```
[0 0 0 0 divide over under invalid]
```

In other words, `flags = divide + 2*over + 4*under + 8*invalid`.

If an object is provided, its write method should take one argument, a string.

Returns**h**

[callable, log instance or None] The old error handler.

See also:

[*seterr*](#), [*geterr*](#), [*geterrcall*](#)

Notes

Concurrency note: see [*Floating point error handling*](#)

Examples

Callback upon error:

```
>>> def err_handler(type, flag):
...     print("Floating point error (%s), with flag %s" % (type, flag))
... 
```

```
>>> import numpy as np
```

```
>>> orig_handler = np.seterrcall(err_handler)
>>> orig_err = np.seterr(all='call')
```

```
>>> np.array([1, 2, 3]) / 0.0
Floating point error (divide by zero), with flag 1
array([inf, inf, inf])
```

```
>>> np.seterrcall(orig_handler)
<function err_handler at 0x...>
>>> np.seterr(**orig_err)
{'divide': 'call', 'over': 'call', 'under': 'call', 'invalid': 'call'}
```

Log error message:

```
>>> class Log:
...     def write(self, msg):
...         print("LOG: %s" % msg)
... 
```

```
>>> log = Log()
>>> saved_handler = np.seterrcall(log)
>>> save_err = np.seterr(all='log')
```

```
>>> np.array([1, 2, 3]) / 0.0
LOG: Warning: divide by zero encountered in divide
array([inf, inf, inf])
```

```
>>> np.seterrcall(orig_handler)
<numpy.Log object at 0x...>
>>> np.seterr(**orig_err)
{'divide': 'log', 'over': 'log', 'under': 'log', 'invalid': 'log'}
```

`numpy.geterrcall()`

Return the current callback function used on floating-point errors.

When the error handling for a floating-point error (one of “divide”, “over”, “under”, or “invalid”) is set to ‘call’ or ‘log’, the function that is called or the log instance that is written to is returned by `geterrcall`. This function or log instance has been set with `seterrcall`.

Returns

`errobj`

[callable, log instance or None] The current error handler. If no handler was set through `seterrcall`, None is returned.

See also:

`seterrcall`, `seterr`, `geterr`

Notes

For complete documentation of the types of floating-point exceptions and treatment options, see `seterr`.

Concurrency note: see *Floating point error handling*

Examples

```
>>> import numpy as np
>>> np.geterrcall() # we did not yet set a handler, returns None
```

```
>>> orig_settings = np.seterr(all='call')
>>> def err_handler(type, flag):
...     print("Floating point error (%s), with flag %s" % (type, flag))
>>> old_handler = np.seterrcall(err_handler)
>>> np.array([1, 2, 3]) / 0.0
Floating point error (divide by zero), with flag 1
array([inf, inf, inf])
```

```
>>> cur_handler = np.geterrcall()
>>> cur_handler is err_handler
True
>>> old_settings = np.seterr(**orig_settings) # restore original
>>> old_handler = np.seterrcall(None) # restore original
```

```
class numpy.errstate (**kwargs)
```

Context manager for floating-point error handling.

Using an instance of `errstate` as a context manager allows statements in that context to execute with a known error handling behavior. Upon entering the context the error handling is set with `seterr` and `seterrcall`, and upon exiting it is reset to what it was before.

Changed in version 1.17.0: `errstate` is also usable as a function decorator, saving a level of indentation if an entire function is wrapped.

Changed in version 2.0: `errstate` is now fully thread and asyncio safe, but may not be entered more than once. It is not safe to decorate async functions using `errstate`.

Parameters

kwargs

[[divide, over, under, invalid]] Keyword arguments. The valid keywords are the possible floating-point exceptions. Each keyword should have a string value that defines the treatment for the particular error. Possible values are {'ignore', 'warn', 'raise', 'call', 'print', 'log'}.

Methods

<code>__call__(func)</code>	Call self as a function.
-----------------------------	--------------------------

method

```
errstate.__call__(func)
```

Call self as a function.

See also:

`seterr`, `geterr`, `seterrcall`, `geterrcall`

Notes

For complete documentation of the types of floating-point exceptions and treatment options, see `seterr`.

Concurrency note: see *Floating point error handling*

Examples

```
>>> import numpy as np
>>> olderr = np.seterr(all='ignore') # Set error handling to known state.
```

```
>>> np.arange(3) / 0.
array([nan, inf, inf])
>>> with np.errstate(divide='ignore'):
...     np.arange(3) / 0.
array([nan, inf, inf])
```

```
>>> np.sqrt(-1)
np.float64(nan)
>>> with np.errstate(invalid='raise'):
...     np.sqrt(-1)
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
FloatingPointError: invalid value encountered in sqrt
```

Outside the context the error handling behavior has not changed:

```
>>> np.geterr()
{'divide': 'ignore', 'over': 'ignore', 'under': 'ignore', 'invalid': 'ignore'}
>>> olderr = np.seterr(**olderr) # restore original state
```

1.4.8 Functional programming

<code>apply_along_axis(func1d, axis, arr, *args, ...)</code>	Apply a function to 1-D slices along the given axis.
<code>apply_over_axes(func, a, axes)</code>	Apply a function repeatedly over multiple axes.
<code>vectorize([pyfunc, otypes, doc, excluded, ...])</code>	Returns an object that acts like pyfunc, but takes arrays as input.
<code>frompyfunc(func, /, nin, nout, *[, identity])</code>	Takes an arbitrary Python function and returns a NumPy ufunc.
<code>piecewise(x, condlist, funclist, *args, **kw)</code>	Evaluate a piecewise-defined function.

`numpy.apply_along_axis` (*func1d*, *axis*, *arr*, **args*, ***kwargs*)

Apply a function to 1-D slices along the given axis.

Execute *func1d*(*a*, **args*, ***kwargs*) where *func1d* operates on 1-D arrays and *a* is a 1-D slice of *arr* along *axis*.

This is equivalent to (but faster than) the following use of *ndindex* and *s_*, which sets each of *ii*, *jj*, and *kk* to a tuple of indices:

```
Ni, Nk = a.shape[:axis], a.shape[axis+1:]
for ii in ndindex(Ni):
    for kk in ndindex(Nk):
        f = func1d(arr[ii + s_[:,] + kk])
        Nj = f.shape
        for jj in ndindex(Nj):
            out[ii + jj + kk] = f[jj]
```

Equivalently, eliminating the inner loop, this can be expressed as:

```
Ni, Nk = a.shape[:axis], a.shape[axis+1:]
for ii in ndindex(Ni):
    for kk in ndindex(Nk):
        out[ii + s_[:,] + kk] = func1d(arr[ii + s_[:,] + kk])
```

Parameters

func1d

[function (M,) -> (Nj,...)] This function should accept 1-D arrays. It is applied to 1-D slices of *arr* along the specified axis.

axis[integer] Axis along which *arr* is sliced.**arr**

[ndarray (Ni..., M, Nk...)] Input array.

args[any] Additional arguments to *func1d*.**kwargs**[any] Additional named arguments to *func1d*.**Returns****out**

[ndarray (Ni..., Nj..., Nk...)] The output array. The shape of *out* is identical to the shape of *arr*, except along the *axis* dimension. This axis is removed, and replaced with new dimensions equal to the shape of the return value of *func1d*. So if *func1d* returns a scalar *out* will have one fewer dimensions than *arr*.

See also:***apply_over_axes***

Apply a function repeatedly over multiple axes.

Examples

```
>>> import numpy as np
>>> def my_func(a):
...     """Average first and last element of a 1-D array"""
...     return (a[0] + a[-1]) * 0.5
>>> b = np.array([[1,2,3], [4,5,6], [7,8,9]])
>>> np.apply_along_axis(my_func, 0, b)
array([4., 5., 6.])
>>> np.apply_along_axis(my_func, 1, b)
array([2., 5., 8.]
```

For a function that returns a 1D array, the number of dimensions in *outarr* is the same as *arr*.

```
>>> b = np.array([[8,1,7], [4,3,9], [5,2,6]])
>>> np.apply_along_axis(sorted, 1, b)
array([[1, 7, 8],
       [3, 4, 9],
       [2, 5, 6]])
```

For a function that returns a higher dimensional array, those dimensions are inserted in place of the *axis* dimension.

```
>>> b = np.array([[1,2,3], [4,5,6], [7,8,9]])
>>> np.apply_along_axis(np.diag, -1, b)
array([[1, 0, 0],
       [0, 2, 0],
       [0, 0, 3]],
      [[4, 0, 0],
       [0, 5, 0],
       [0, 0, 6]],
      [[7, 0, 0],
```

(continues on next page)

(continued from previous page)

```
[0, 8, 0],
[0, 0, 9]]])
```

`numpy.apply_over_axes` (*func*, *a*, *axes*)

Apply a function repeatedly over multiple axes.

func is called as *res* = *func*(*a*, *axis*), where *axis* is the first element of *axes*. The result *res* of the function call must have either the same dimensions as *a* or one less dimension. If *res* has one less dimension than *a*, a dimension is inserted before *axis*. The call to *func* is then repeated for each axis in *axes*, with *res* as the first argument.

Parameters

func

[function] This function must take two arguments, *func*(*a*, *axis*).

a

[array_like] Input array.

axes

[array_like] Axes over which *func* is applied; the elements must be integers.

Returns

apply_over_axis

[ndarray] The output array. The number of dimensions is the same as *a*, but the shape can be different. This depends on whether *func* changes the shape of its output with respect to its input.

See also:

[*apply_along_axis*](#)

Apply a function to 1-D slices of an array along the given axis.

Notes

This function is equivalent to tuple axis arguments to reorderable ufuncs with `keepdims=True`. Tuple axis arguments to ufuncs have been available since version 1.7.0.

Examples

```
>>> import numpy as np
>>> a = np.arange(24).reshape(2,3,4)
>>> a
array([[[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]],
       [[12, 13, 14, 15],
        [16, 17, 18, 19],
        [20, 21, 22, 23]]])
```

Sum over axes 0 and 2. The result has same number of dimensions as the original array:

```
>>> np.apply_over_axes(np.sum, a, [0,2])
array([[[ 60],
        [ 92],
        [124]]])
```

Tuple axis arguments to ufuncs are equivalent:

```
>>> np.sum(a, axis=(0,2), keepdims=True)
array([[[ 60],
        [ 92],
        [124]]])
```

```
class numpy.vectorize (pyfunc=np._NoValue, otypes=None, doc=None, excluded=None, cache=False,
                        signature=None)
```

Returns an object that acts like pyfunc, but takes arrays as input.

Define a vectorized function which takes a nested sequence of objects or numpy arrays as inputs and returns a single numpy array or a tuple of numpy arrays. The vectorized function evaluates *pyfunc* over successive tuples of the input arrays like the python map function, except it uses the broadcasting rules of numpy.

The data type of the output of *vectorized* is determined by calling the function with the first element of the input. This can be avoided by specifying the *otypes* argument.

Parameters

pyfunc

[callable, optional] A python function or method. Can be omitted to produce a decorator with keyword arguments.

otypes

[str or list of dtypes, optional] The output data type. It must be specified as either a string of typecode characters or a list of data type specifiers. There should be one data type specifier for each output.

doc

[str, optional] The docstring for the function. If None, the docstring will be the `pyfunc.__doc__`.

excluded

[set, optional] Set of strings or integers representing the positional or keyword arguments for which the function will not be vectorized. These will be passed directly to *pyfunc* unmodified.

cache

[bool, optional] If neither *otypes* nor *signature* are provided, and *cache* is `True`, then cache the number of outputs.

signature

[string, optional] Generalized universal function signature, e.g., $(m, n) \rightarrow (m)$ for vectorized matrix-vector multiplication. If provided, *pyfunc* will be called with (and expected to return) arrays with shapes given by the size of corresponding core dimensions. By default, *pyfunc* is assumed to take scalars as input and output.

Methods

```
__call__(*args, **kwargs)
```

Call self as a function.

method

```
vectorize.__call__(*args, **kwargs)
```

Call self as a function.

Returns

out

[callable] A vectorized function if `pyfunc` was provided, a decorator otherwise.

See also:

frompyfunc

Takes an arbitrary Python function and returns a ufunc

Notes

The *vectorize* function is provided primarily for convenience, not for performance. The implementation is essentially a for loop.

If neither *otypes* nor *signature* are specified, then a call to the function with the first argument will be used to determine the number of outputs. The results of this call will be cached if *cache* is *True* to prevent calling the function twice. However, to implement the cache, the original function must be wrapped which will slow down subsequent calls, so only do this if your function is expensive.

The new keyword argument interface and *excluded* argument support further degrades performance.

References

[1]

Examples

```
>>> import numpy as np
>>> def myfunc(a, b):
...     "Return a-b if a>b, otherwise return a+b"
...     if a > b:
...         return a - b
...     else:
...         return a + b
```

```
>>> vfunc = np.vectorize(myfunc)
>>> vfunc([1, 2, 3, 4], 2)
array([3, 4, 1, 2])
```

The docstring is taken from the input function to *vectorize* unless it is specified:

```
>>> vfunc.__doc__
'Return a-b if a>b, otherwise return a+b'
>>> vfunc = np.vectorize(myfunc, doc='Vectorized `myfunc`')
>>> vfunc.__doc__
'Vectorized `myfunc`'
```

The output type is determined by evaluating the first element of the input, unless it is specified:

```
>>> out = vfunc([1, 2, 3, 4], 2)
>>> type(out[0])
<class 'numpy.int64'>
>>> vfunc = np.vectorize(myfunc, otypes=[float])
>>> out = vfunc([1, 2, 3, 4], 2)
```

(continues on next page)

(continued from previous page)

```
>>> type(out[0])
<class 'numpy.float64'>
```

The *excluded* argument can be used to prevent vectorizing over certain arguments. This can be useful for array-like arguments of a fixed length such as the coefficients for a polynomial as in *polyval*:

```
>>> def mypolyval(p, x):
...     _p = list(p)
...     res = _p.pop(0)
...     while _p:
...         res = res*x + _p.pop(0)
...     return res
```

Here, we exclude the zeroth argument from vectorization whether it is passed by position or keyword.

```
>>> vpolyval = np.vectorize(mypolyval, excluded={0, 'p'})
>>> vpolyval([1, 2, 3], x=[0, 1])
array([3, 6])
>>> vpolyval(p=[1, 2, 3], x=[0, 1])
array([3, 6])
```

The *signature* argument allows for vectorizing functions that act on non-scalar arrays of fixed length. For example, you can use it for a vectorized calculation of Pearson correlation coefficient and its p-value:

```
>>> import scipy.stats
>>> pearsonr = np.vectorize(scipy.stats.pearsonr,
...                         signature='(n), (n)->(), ()')
>>> pearsonr([[0, 1, 2, 3]], [[1, 2, 3, 4], [4, 3, 2, 1]])
(array([ 1., -1.]), array([ 0., 0.]))
```

Or for a vectorized convolution:

```
>>> convolve = np.vectorize(np.convolve, signature='(n), (m)->(k)')
>>> convolve(np.eye(4), [1, 2, 1])
array([[1., 2., 1., 0., 0., 0.],
       [0., 1., 2., 1., 0., 0.],
       [0., 0., 1., 2., 1., 0.],
       [0., 0., 0., 1., 2., 1.]])
```

Decorator syntax is supported. The decorator can be called as a function to provide keyword arguments:

```
>>> @np.vectorize
... def identity(x):
...     return x
...
>>> identity([0, 1, 2])
array([0, 1, 2])
>>> @np.vectorize(otypes=[float])
... def as_float(x):
...     return x
...
>>> as_float([0, 1, 2])
array([0., 1., 2.])
```

`numpy.frompyfunc(func, /, nin, nout, *, identity)`

Takes an arbitrary Python function and returns a NumPy ufunc.

Can be used, for example, to add broadcasting to a built-in Python function (see Examples section).

Parameters**func**

[Python function object] An arbitrary Python function.

nin

[int] The number of input arguments.

nout

[int] The number of objects returned by *func*.

identity

[object, optional] The value to use for the *identity* attribute of the resulting object. If specified, this is equivalent to setting the underlying C *identity* field to `PyUFunc_IdentityValue`. If omitted, the identity is set to `PyUFunc_None`. Note that this is *_not_* equivalent to setting the identity to `None`, which implies the operation is reorderable.

Returns**out**

[ufunc] Returns a NumPy universal function (`ufunc`) object.

See also:

vectorize

Evaluates `pyfunc` over input arrays using broadcasting rules of `numpy`.

Notes

The returned `ufunc` always returns `PyObject` arrays.

Examples

Use `frompyfunc` to add broadcasting to the Python function `oct`:

```
>>> import numpy as np
>>> oct_array = np.frompyfunc(oct, 1, 1)
>>> oct_array(np.array((10, 30, 100)))
array(['0o12', '0o36', '0o144'], dtype=object)
>>> np.array((oct(10), oct(30), oct(100))) # for comparison
array(['0o12', '0o36', '0o144'], dtype='<U5')
```

`numpy.piecewise` (*x*, *condlist*, *funclist*, **args*, ***kw*)

Evaluate a piecewise-defined function.

Given a set of conditions and corresponding functions, evaluate each function on the input data wherever its condition is true.

Parameters**x**

[ndarray or scalar] The input domain.

condlist

[list of bool arrays or bool scalars] Each boolean array corresponds to a function in *funclist*. Wherever *condlist*[*i*] is True, *funclist*[*i*](*x*) is used as the output value.

Each boolean array in *condlist* selects a piece of *x*, and should therefore be of the same shape as *x*.

The length of *condlist* must correspond to that of *funclist*. If one extra function is given, i.e. if `len(funclist) == len(condlist) + 1`, then that extra function is the default value, used wherever all conditions are false.

funclist

[list of callables, `f(x,*args,**kw)`, or scalars] Each function is evaluated over *x* wherever its corresponding condition is True. It should take a 1d array as input and give a 1d array or a scalar value as output. If, instead of a callable, a scalar is provided then a constant function (`lambda x: scalar`) is assumed.

args

[tuple, optional] Any further arguments given to *piecewise* are passed to the functions upon execution, i.e., if called `piecewise(..., ..., 1, 'a')`, then each function is called as `f(x, 1, 'a')`.

kw

[dict, optional] Keyword arguments used in calling *piecewise* are passed to the functions upon execution, i.e., if called `piecewise(..., ..., alpha=1)`, then each function is called as `f(x, alpha=1)`.

Returns

out

[ndarray] The output is the same shape and type as *x* and is found by calling the functions in *funclist* on the appropriate portions of *x*, as defined by the boolean arrays in *condlist*. Portions not covered by any condition have a default value of 0.

See also:

choose, *select*, *where*

Notes

This is similar to *choose* or *select*, except that functions are evaluated on elements of *x* that satisfy the corresponding condition from *condlist*.

The result is:

```
out = | --
      | funclist[0] (x[condlist[0]])
      | funclist[1] (x[condlist[1]])
      | ...
      | funclist[n2] (x[condlist[n2]])
      | --
```

Examples

```
>>> import numpy as np
```

Define the signum function, which is -1 for $x < 0$ and +1 for $x \geq 0$.

```
>>> x = np.linspace(-2.5, 2.5, 6)
>>> np.piecewise(x, [x < 0, x >= 0], [-1, 1])
array([-1., -1., -1.,  1.,  1.,  1.])
```

Define the absolute value, which is $-x$ for $x < 0$ and x for $x \geq 0$.

```
>>> np.piecewise(x, [x < 0, x >= 0], [lambda x: -x, lambda x: x])
array([2.5,  1.5,  0.5,  0.5,  1.5,  2.5])
```

Apply the same function to a scalar value.

```
>>> y = -2
>>> np.piecewise(y, [y < 0, y >= 0], [lambda x: -x, lambda x: x])
array(2)
```

1.4.9 Input and output

NumPy binary files (npz, npy)

<code>load(file[, mmap_mode, allow_pickle, ...])</code>	Load arrays or pickled objects from .npy, .npz or pickled files.
<code>save(file, arr[, allow_pickle])</code>	Save an array to a binary file in NumPy .npy format.
<code>savez(file, *args[, allow_pickle])</code>	Save several arrays into a single file in uncompressed .npz format.
<code>savez_compressed(file, *args[, allow_pickle])</code>	Save several arrays into a single file in compressed .npz format.
<code>lib.npyio.NpzFile(fid)</code>	A dictionary-like object with lazy-loading of files in the zipped archive provided on construction.

```
numpy.load(file, mmap_mode=None, allow_pickle=False, fix_imports=True, encoding='ASCII', *,
           max_header_size=10000)
```

Load arrays or pickled objects from .npy, .npz or pickled files.

Warning: Loading files that contain object arrays uses the `pickle` module, which is not secure against erroneous or maliciously constructed data. Consider passing `allow_pickle=False` to load data that is known not to contain object arrays for the safer handling of untrusted sources.

Parameters

file

[file-like object, string, or `pathlib.Path`] The file to read. File-like objects must support the `seek()` and `read()` methods and must always be opened in binary mode. Pickled files require that the file-like object support the `readline()` method as well.

mmap_mode

[{None, 'r+', 'r', 'w+', 'c'}, optional] If not None, then memory-map the file, using the given mode (see [numpy.memmap](#) for a detailed description of the modes). A memory-mapped array is kept on disk. However, it can be accessed and sliced like any ndarray. Memory mapping is especially useful for accessing small fragments of large files without reading the entire file into memory.

allow_pickle

[bool, optional] Allow loading pickled object arrays stored in npy files. Reasons for disallowing pickles include security, as loading pickled data can execute arbitrary code. If pickles are disallowed, loading object arrays will fail. Default: False

fix_imports

[bool, optional] Only useful when loading Python 2 generated pickled files, which includes npy/npz files containing object arrays. If *fix_imports* is True, pickle will try to map the old Python 2 names to the new names used in Python 3.

encoding

[str, optional] What encoding to use when reading Python 2 strings. Only useful when loading Python 2 generated pickled files, which includes npy/npz files containing object arrays. Values other than 'latin1', 'ASCII', and 'bytes' are not allowed, as they can corrupt numerical data. Default: 'ASCII'

max_header_size

[int, optional] Maximum allowed size of the header. Large headers may not be safe to load securely and thus require explicitly passing a larger value. See [ast.literal_eval](#) for details. This option is ignored when *allow_pickle* is passed. In that case the file is by definition trusted and the limit is unnecessary.

Returns**result**

[array, tuple, dict, etc.] Data stored in the file. For .npz files, the returned instance of NpzFile class must be closed to avoid leaking file descriptors.

Raises**OSError**

If the input file does not exist or cannot be read.

UnpicklingError

If *allow_pickle*=True, but the file cannot be loaded as a pickle.

ValueError

The file contains an object array, but *allow_pickle*=False given.

EOFError

When calling `np.load` multiple times on the same file handle, if all data has already been read

See also:

[save](#), [savez](#), [savez_compressed](#), [loadtxt](#)
[memmap](#)

Create a memory-map to an array stored in a file on disk.

[lib.format.open_memmap](#)

Create or load a memory-mapped .npy file.

Notes

- If the file contains pickle data, then whatever object is stored in the pickle is returned.
- If the file is a `.npy` file, then a single array is returned.
- If the file is a `.npz` file, then a dictionary-like object is returned, containing `{filename: array}` key-value pairs, one for each file in the archive.
- If the file is a `.npz` file, the returned value supports the context manager protocol in a similar fashion to the `open` function:

```
with load('foo.npz') as data:
    a = data['a']
```

The underlying file descriptor is closed when exiting the `'with'` block.

Examples

```
>>> import numpy as np
```

Store data to disk, and load it again:

```
>>> np.save('/tmp/123', np.array([[1, 2, 3], [4, 5, 6]]))
>>> np.load('/tmp/123.npy')
array([[1, 2, 3],
       [4, 5, 6]])
```

Store compressed data to disk, and load it again:

```
>>> a=np.array([[1, 2, 3], [4, 5, 6]])
>>> b=np.array([1, 2])
>>> np.savez('/tmp/123.npz', a=a, b=b)
>>> data = np.load('/tmp/123.npz')
>>> data['a']
array([[1, 2, 3],
       [4, 5, 6]])
>>> data['b']
array([1, 2])
>>> data.close()
```

Mem-map the stored array, and then access the second row directly from disk:

```
>>> X = np.load('/tmp/123.npz', mmap_mode='r')
>>> X[1, :]
memmap([4, 5, 6])
```

`numpy.save(file, arr, allow_pickle=True)`

Save an array to a binary file in NumPy `.npy` format.

Parameters

file

[file, str, or pathlib.Path] File or filename to which the data is saved. If file is a file-object, then the filename is unchanged. If file is a string or Path, a `.npy` extension will be appended to the filename if it does not already have one.

arr

[array_like] Array data to be saved.

allow_pickle

[bool, optional] Allow saving object arrays using Python pickles. Reasons for disallowing pickles include security (loading pickled data can execute arbitrary code) and portability (pickled objects may not be loadable on different Python installations, for example if the stored objects require libraries that are not available, and not all pickled data is compatible between different versions of Python). Default: True

See also:**savez**

Save several arrays into a .npz archive

saveetxt, load

Notes

For a description of the .npy format, see `numpy.lib.format`.

Any data saved to the file is appended to the end of the file.

Examples

```
>>> import numpy as np
```

```
>>> from tempfile import TemporaryFile
>>> outfile = TemporaryFile()
```

```
>>> x = np.arange(10)
>>> np.save(outfile, x)
```

```
>>> _ = outfile.seek(0) # Only needed to simulate closing & reopening file
>>> np.load(outfile)
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
```

```
>>> with open('test.npy', 'wb') as f:
...     np.save(f, np.array([1, 2]))
...     np.save(f, np.array([1, 3]))
>>> with open('test.npy', 'rb') as f:
...     a = np.load(f)
...     b = np.load(f)
>>> print(a, b)
# [1 2] [1 3]
```

`numpy.savez` (*file*, **args*, *allow_pickle*=True, ***kwds*)

Save several arrays into a single file in uncompressed .npz format.

Provide arrays as keyword arguments to store them under the corresponding name in the output file: `savez(fn, x=x, y=y)`.

If arrays are specified as positional arguments, i.e., `savez(fn, x, y)`, their names will be `arr_0`, `arr_1`, etc.

Parameters

file

[file, str, or pathlib.Path] Either the filename (string) or an open file (file-like object) where the data will be saved. If file is a string or a Path, the `.npz` extension will be appended to the filename if it is not already there.

args

[Arguments, optional] Arrays to save to the file. Please use keyword arguments (see *kwds* below) to assign names to arrays. Arrays specified as args will be named “arr_0”, “arr_1”, and so on.

allow_pickle

[bool, optional] Allow saving object arrays using Python pickles. Reasons for disallowing pickles include security (loading pickled data can execute arbitrary code) and portability (pickled objects may not be loadable on different Python installations, for example if the stored objects require libraries that are not available, and not all pickled data is compatible between different versions of Python). Default: True

kwds

[Keyword arguments, optional] Arrays to save to the file. Each array will be saved to the output file with its corresponding keyword name.

Returns

None

See also:***save***

Save a single array to a binary file in NumPy format.

savetxt

Save an array to a file as plain text.

savez_compressed

Save several arrays into a compressed `.npz` archive

Notes

The `.npz` file format is a zipped archive of files named after the variables they contain. The archive is not compressed and each file in the archive contains one variable in `.npy` format. For a description of the `.npy` format, see *numpy.lib.format*.

When opening the saved `.npz` file with *load* a *NpzFile* object is returned. This is a dictionary-like object which can be queried for its list of arrays (with the `.files` attribute), and for the arrays themselves.

Keys passed in *kwds* are used as filenames inside the ZIP archive. Therefore, keys should be valid filenames; e.g., avoid keys that begin with `/` or contain `..`

When naming variables with keyword arguments, it is not possible to name a variable `file`, as this would cause the `file` argument to be defined twice in the call to *savez*.

Examples

```
>>> import numpy as np
>>> from tempfile import TemporaryFile
>>> outfile = TemporaryFile()
>>> x = np.arange(10)
>>> y = np.sin(x)
```

Using `savez` with `*args`, the arrays are saved with default names.

```
>>> np.savez(outfile, x, y)
>>> _ = outfile.seek(0) # Only needed to simulate closing & reopening file
>>> npzfile = np.load(outfile)
>>> npzfile.files
['arr_0', 'arr_1']
>>> npzfile['arr_0']
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
```

Using `savez` with `**kwds`, the arrays are saved with the keyword names.

```
>>> outfile = TemporaryFile()
>>> np.savez(outfile, x=x, y=y)
>>> _ = outfile.seek(0)
>>> npzfile = np.load(outfile)
>>> sorted(npzfile.files)
['x', 'y']
>>> npzfile['x']
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
```

`numpy.savez_compressed(file, *args, allow_pickle=True, **kwds)`

Save several arrays into a single file in compressed `.npz` format.

Provide arrays as keyword arguments to store them under the corresponding name in the output file: `savez_compressed(fn, x=x, y=y)`.

If arrays are specified as positional arguments, i.e., `savez_compressed(fn, x, y)`, their names will be `arr_0`, `arr_1`, etc.

Parameters

file

[file, str, or `pathlib.Path`] Either the filename (string) or an open file (file-like object) where the data will be saved. If file is a string or a `Path`, the `.npz` extension will be appended to the filename if it is not already there.

args

[Arguments, optional] Arrays to save to the file. Please use keyword arguments (see *kwds* below) to assign names to arrays. Arrays specified as args will be named “arr_0”, “arr_1”, and so on.

allow_pickle

[bool, optional] Allow saving object arrays using Python pickles. Reasons for disallowing pickles include security (loading pickled data can execute arbitrary code) and portability (pickled objects may not be loadable on different Python installations, for example if the stored objects require libraries that are not available, and not all pickled data is compatible between different versions of Python). Default: True

kwds

[Keyword arguments, optional] Arrays to save to the file. Each array will be saved to the output

file with its corresponding keyword name.

Returns

None

See also:

numpy.save

Save a single array to a binary file in NumPy format.

numpy.savetxt

Save an array to a file as plain text.

numpy.savez

Save several arrays into an uncompressed `.npz` file format

numpy.load

Load the files created by `savez_compressed`.

Notes

The `.npz` file format is a zipped archive of files named after the variables they contain. The archive is compressed with `zipfile.ZIP_DEFLATED` and each file in the archive contains one variable in `.npy` format. For a description of the `.npy` format, see *numpy.lib.format*.

When opening the saved `.npz` file with *load* a *NpzFile* object is returned. This is a dictionary-like object which can be queried for its list of arrays (with the `.files` attribute), and for the arrays themselves.

Examples

```
>>> import numpy as np
>>> test_array = np.random.rand(3, 2)
>>> test_vector = np.random.rand(4)
>>> np.savez_compressed('/tmp/123', a=test_array, b=test_vector)
>>> loaded = np.load('/tmp/123.npz')
>>> print(np.array_equal(test_array, loaded['a']))
True
>>> print(np.array_equal(test_vector, loaded['b']))
True
```

The format of these binary file types is documented in *numpy.lib.format*

Text files

<i>loadtxt</i> (fname[, dtype, comments, delimiter, ...])	Load data from a text file.
<i>savetxt</i> (fname, X[, fmt, delimiter, newline, ...])	Save an array to a text file.
<i>genfromtxt</i> (fname[, dtype, comments, ...])	Load data from a text file, with missing values handled as specified.
<i>fromregex</i> (file, regexp, dtype[, encoding])	Construct an array from a text file, using regular expression parsing.
<i>fromstring</i> (string[, dtype, count, like])	A new 1-D array initialized from text data in a string.
<i>ndarray.tofile</i> (fid, /[, sep, format])	Write array to a file as text or binary (default).
<i>ndarray.tolist</i> ()	Return the array as an <code>a.ndim</code> -levels deep nested list of Python scalars.

`numpy.savetxt` (*fname*, *X*, *fmt*='%1.18e', *delimiter*=' ', *newline*='\n', *header*='', *footer*='', *comments*='# ', *encoding*=None)

Save an array to a text file.

Parameters

fname

[filename, file handle or pathlib.Path] If the filename ends in `.gz`, the file is automatically saved in compressed gzip format. `loadtxt` understands gzipped files transparently.

X

[1D or 2D array_like] Data to be saved to a text file.

fmt

[str or sequence of strs, optional] A single format (`%10.5f`), a sequence of formats, or a multi-format string, e.g. `'Iteration %d - %10.5f'`, in which case *delimiter* is ignored. For complex *X*, the legal options for *fmt* are:

- a single specifier, `fmt='% .4e'`, resulting in numbers formatted like `' (%s+%sj) ' % (fmt, fmt)`
- a full string specifying every real and imaginary part, e.g. `' % .4e %+ .4ej % .4e %+ .4ej % .4e %+ .4ej'` for 3 columns
- a list of specifiers, one per column - in this case, the real and imaginary part must have separate specifiers, e.g. `['% .3e + % .3ej', ' (%.15e%+.15ej) ']` for 2 columns

delimiter

[str, optional] String or character separating columns.

newline

[str, optional] String or character separating lines.

header

[str, optional] String that will be written at the beginning of the file.

footer

[str, optional] String that will be written at the end of the file.

comments

[str, optional] String that will be prepended to the header and footer strings, to mark them as comments. Default: `#`, as expected by e.g. `numpy.loadtxt`.

encoding

[{None, str}, optional] Encoding used to encode the outputfile. Does not apply to output streams. If the encoding is something other than `'bytes'` or `'latin1'` you will not be able to load the file in NumPy versions < 1.14. Default is `'latin1'`.

See also:

`save`

Save an array to a binary file in NumPy `.npy` format

`savez`

Save several arrays into an uncompressed `.npz` archive

`savez_compressed`

Save several arrays into a compressed `.npz` archive

Notes

Further explanation of the *fmt* parameter (`%[flag]width[.precision]specifier`):

flags:

- : left justify
- + : Forces to precede result with + or -.
- 0 : Left pad the number with zeros instead of space (see width).

width:

Minimum number of characters to be printed. The value is not truncated if it has more characters.

precision:

- For integer specifiers (eg. `d`, `i`, `o`, `x`), the minimum number of digits.
- For `e`, `E` and `f` specifiers, the number of digits to print after the decimal point.
- For `g` and `G`, the maximum number of significant digits.
- For `s`, the maximum number of characters.

specifiers:

- `c` : character
- `d` or `i` : signed decimal integer
- `e` or `E` : scientific notation with `e` or `E`.
- `f` : decimal floating point
- `g`, `G` : use the shorter of `e`, `E` or `f`
- `o` : signed octal
- `s` : string of characters
- `u` : unsigned decimal integer
- `x`, `X` : unsigned hexadecimal integer

This explanation of `fmt` is not complete, for an exhaustive specification see [1].

References

[1]

Examples

```
>>> import numpy as np
>>> x = y = z = np.arange(0.0, 5.0, 1.0)
>>> np.savetxt('test.out', x, delimiter=',')    # X is an array
>>> np.savetxt('test.out', (x,y,z))           # x,y,z equal sized 1D arrays
>>> np.savetxt('test.out', x, fmt='%1.4e')      # use exponential notation
```

`numpy.genfromtxt` (*fname*, *dtype*=<class 'float'>, *comments*='#', *delimiter*=None, *skip_header*=0, *skip_footer*=0, *converters*=None, *missing_values*=None, *filling_values*=None, *usecols*=None, *names*=None, *excludelist*=None, *deletechars*="!#\$%&'()*+,-./:;<=>?@[\\]^_{|}~", *replace_space*='_', *autostrip*=False, *case_sensitive*=True, *defaultfmt*='%i', *unpack*=None, *usemask*=False, *loose*=True, *invalid_raise*=True, *max_rows*=None, *encoding*=None, *, *ndmin*=0, *like*=None)

Load data from a text file, with missing values handled as specified.

Each line past the first *skip_header* lines is split at the *delimiter* character, and characters following the *comments* character are discarded.

Parameters

fname

[file, str, pathlib.Path, list of str, generator] File, filename, list, or generator to read. If the filename extension is `.gz` or `.bz2`, the file is first decompressed. Note that generators must return bytes or strings. The strings in a list or produced by a generator are treated as lines.

dtype

[dtype, optional] Data type of the resulting array. If a structured dtype, the output array will be 1D and structured where each field corresponds to one column. If None, the dtype of each column will be inferred automatically, and the output array will be structured only if either the dtypes are not all the same or if *names* is not None.

comments

[str, optional] The character used to indicate the start of a comment. All the characters occurring on a line after a comment are discarded.

delimiter

[str, int, or sequence, optional] The string used to separate values. By default, any consecutive whitespaces act as delimiter. An integer or sequence of integers can also be provided as width(s) of each field.

skiprows

[int, optional] *skiprows* was removed in numpy 1.10. Please use *skip_header* instead.

skip_header

[int, optional] The number of lines to skip at the beginning of the file.

skip_footer

[int, optional] The number of lines to skip at the end of the file.

converters

[variable, optional] The set of functions that convert the data of a column to a value. The converters can also be used to provide a default value for missing data: `converters = {3: lambda s: float(s or 0)}`.

missing

[variable, optional] *missing* was removed in numpy 1.10. Please use *missing_values* instead.

missing_values

[variable, optional] The set of strings corresponding to missing data.

filling_values

[variable, optional] The set of values to be used as default when the data are missing.

usecols

[sequence, optional] Which columns to read, with 0 being the first. For example, `usecols = (1, 4, 5)` will extract the 2nd, 5th and 6th columns.

names

[{None, True, str, sequence}, optional] If *names* is True, the output will be a structured array whose field names are read from the first line after the first *skip_header* lines. This line can optionally be preceded by a comment delimiter. Any content before the comment delimiter is discarded. If *names* is a sequence or a single string of comma-separated names, the output

is a structured array whose field names are taken from *names*. If *names* is *None*, the output is structured only if *dtype* is structured, in which case the field names are taken from *dtype*.

excludelist

[sequence, optional] A list of names to exclude. This list is appended to the default list ['return', 'file', 'print']. Excluded names are appended with an underscore: for example, *file* would become *file_*.

deletechars

[str, optional] A string combining invalid characters that must be deleted from the names.

defaultfmt

[str, optional] A format used to define default field names, such as “f%i” or “f_%02i”.

autostrip

[bool, optional] Whether to automatically strip white spaces from the variables.

replace_space

[char, optional] Character(s) used in replacement of white spaces in the variable names. By default, use a ‘_’.

case_sensitive

[[True, False, ‘upper’, ‘lower’], optional] If True, field names are case sensitive. If False or ‘upper’, field names are converted to upper case. If ‘lower’, field names are converted to lower case.

unpack

[bool, optional] If True, the returned array is transposed, so that arguments may be unpacked using *x, y, z = genfromtxt(...)*. When used with a structured data-type, arrays are returned for each field. Default is False.

usemask

[bool, optional] If True, return a masked array. If False, return a regular array.

loose

[bool, optional] If True, do not raise errors for invalid values.

invalid_raise

[bool, optional] If True, an exception is raised if an inconsistency is detected in the number of columns. If False, a warning is emitted and the offending lines are skipped.

max_rows

[int, optional] The maximum number of rows to read. Must not be used with *skip_footer* at the same time. If given, the value must be at least 1. Default is to read the entire file.

encoding

[str, optional] Encoding used to decode the inputfile. Does not apply when *fname* is a file object. The special value ‘bytes’ enables backward compatibility workarounds that ensure that you receive byte arrays when possible and passes latin1 encoded strings to converters. Override this value to receive unicode arrays and pass strings as input to converters. If set to *None* the system default is used. The default value is ‘bytes’.

Changed in version 2.0: Before NumPy 2, the default was ‘bytes’ for Python 2 compatibility. The default is now *None*.

ndmin

[int, optional] Same parameter as *loadtxt*

New in version 1.23.0.

like

[array_like, optional] Reference object to allow the creation of arrays which are not NumPy

arrays. If an array-like passed in as `like` supports the `__array_function__` protocol, the result will be defined by it. In this case, it ensures the creation of an array object compatible with that passed in via this argument.

New in version 1.20.0.

Returns

out

[ndarray] Data read from the text file. If *usemask* is True, this is a masked array.

See also:

[`numpy.loadtxt`](#)

equivalent function when no data is missing.

Notes

- When spaces are used as delimiters, or when no delimiter has been given as input, there should not be any missing data between two fields.
- When variables are named (either by a flexible dtype or with a *names* sequence), there must not be any header in the file (else a `ValueError` exception is raised).
- Individual values are not stripped of spaces by default. When using a custom converter, make sure the function does remove spaces.
- Custom converters may receive unexpected values due to dtype discovery.

References

[1]

Examples

```
>>> from io import StringIO
>>> import numpy as np
```

Comma delimited file with mixed dtype

```
>>> s = StringIO("1,1.3,abcde")
>>> data = np.genfromtxt(s, dtype=[('myint', 'i8'), ('myfloat', 'f8'),
... ('mystring', 'S5')], delimiter=",")
>>> data
array((1, 1.3, b'abcde'),
      dtype=[('myint', '<i8'), ('myfloat', '<f8'), ('mystring', 'S5')])
```

Using dtype = None

```
>>> _ = s.seek(0) # needed for StringIO example only
>>> data = np.genfromtxt(s, dtype=None,
... names = ['myint', 'myfloat', 'mystring'], delimiter=",")
>>> data
array((1, 1.3, 'abcde'),
      dtype=[('myint', '<i8'), ('myfloat', '<f8'), ('mystring', '<U5')])
```

Specifying dtype and names

```
>>> _ = s.seek(0)
>>> data = np.genfromtxt(s, dtype="i8,f8,S5",
... names=['myint', 'myfloat', 'mystring'], delimiter=",")
>>> data
array((1, 1.3, b'abcde'),
      dtype=[('myint', '<i8'), ('myfloat', '<f8'), ('mystring', 'S5')])
```

An example with fixed-width columns

```
>>> s = StringIO("11.3abcde")
>>> data = np.genfromtxt(s, dtype=None, names=['intvar', 'fltvar', 'strvar'],
... delimiter=[1,3,5])
>>> data
array((1, 1.3, 'abcde'),
      dtype=[('intvar', '<i8'), ('fltvar', '<f8'), ('strvar', '<U5')])
```

An example to show comments

```
>>> f = StringIO('''
... text,# of chars
... hello world,11
... numpy,5''')
>>> np.genfromtxt(f, dtype='S12,S12', delimiter=',')
array([(b'text', b''), (b'hello world', b'11'), (b'numpy', b'5')],
      dtype=[('f0', 'S12'), ('f1', 'S12')])
```

`numpy.fromregex` (*file*, *regex*, *dtype*, *encoding=None*)

Construct an array from a text file, using regular expression parsing.

The returned array is always a structured array, and is constructed from all matches of the regular expression in the file. Groups in the regular expression are converted to fields of the structured array.

Parameters**file**

[file, str, or pathlib.Path] Filename or file object to read.

Changed in version 1.22.0: Now accepts `os.PathLike` implementations.

regex

[str or regex] Regular expression used to parse the file. Groups in the regular expression correspond to fields in the dtype.

dtype

[dtype or list of dtypes] Dtype for the structured array; must be a structured datatype.

encoding

[str, optional] Encoding used to decode the inputfile. Does not apply to input streams.

Returns**output**

[ndarray] The output array, containing the part of the content of *file* that was matched by *regex*. *output* is always a structured array.

Raises**TypeError**

When *dtype* is not a valid dtype for a structured array.

See also:

fromstring, loadtxt

Notes

Dtypes for structured arrays can be specified in several forms, but all forms specify at least the data type and field name. For details see *basics.rec*.

Examples

```
>>> import numpy as np
>>> from io import StringIO
>>> text = StringIO("1312 foo\n1534 bar\n444 qux")

>>> regexp = r"(\d+)\s+(...)" # match [digits, whitespace, anything]
>>> output = np.fromregex(text, regexp,
...                        [('num', np.int64), ('key', 'S3')])
>>> output
array([(1312, b'foo'), (1534, b'bar'), ( 444, b'qux')],
      dtype=[('num', '<i8'), ('key', 'S3')])
>>> output['num']
array([1312, 1534,  444])
```

Raw binary files

<code>fromfile(file[, dtype, count, sep, offset, like])</code>	Construct an array from data in a text or binary file.
<code>ndarray.tofile(fid, /[, sep, format])</code>	Write array to a file as text or binary (default).

String formatting

<code>array2string(a[, max_line_width, precision, ...])</code>	Return a string representation of an array.
<code>array_repr(arr[, max_line_width, precision, ...])</code>	Return the string representation of an array.
<code>array_str(a[, max_line_width, precision, ...])</code>	Return a string representation of the data in an array.
<code>format_float_positional(x[, precision, ...])</code>	Format a floating-point scalar as a decimal string in positional notation.
<code>format_float_scientific(x[, precision, ...])</code>	Format a floating-point scalar as a decimal string in scientific notation.

`numpy.array2string(a, max_line_width=None, precision=None, suppress_small=None, separator=' ', prefix='', *,
formatter=None, threshold=None, edgeitems=None, sign=None, floatmode=None, suffix='',
legacy=None)`

Return a string representation of an array.

Parameters

a
[ndarray] Input array.

max_line_width

[int, optional] Inserts newlines if text is longer than *max_line_width*. Defaults to `numpy.get_printoptions()['linewidth']`.

precision

[int or None, optional] Floating point precision. Defaults to `numpy.get_printoptions()['precision']`.

suppress_small

[bool, optional] Represent numbers “very close” to zero as zero; default is False. Very close is defined by precision: if the precision is 8, e.g., numbers smaller (in absolute value) than 5e-9 are represented as zero. Defaults to `numpy.get_printoptions()['suppress']`.

separator

[str, optional] Inserted between elements.

prefix

[str, optional]

suffix

[str, optional] The length of the prefix and suffix strings are used to respectively align and wrap the output. An array is typically printed as:

`prefix + array2string(a) + suffix`

The output is left-padded by the length of the prefix string, and wrapping is forced at the column `max_line_width - len(suffix)`. It should be noted that the content of prefix and suffix strings are not included in the output.

formatter

[dict of callables, optional] If not None, the keys should indicate the type(s) that the respective formatting function applies to. Callables should return a string. Types that are not specified (by their corresponding keys) are handled by the default formatters. Individual types for which a formatter can be set are:

- ‘bool’
- ‘int’
- ‘timedelta’: a `numpy.timedelta64`
- ‘datetime’: a `numpy.datetime64`
- ‘float’
- ‘longfloat’: 128-bit floats
- ‘complexfloat’
- ‘longcomplexfloat’: composed of two 128-bit floats
- ‘void’: type `numpy.void`
- ‘numpystr’: types `numpy.bytes_` and `numpy.str_`

Other keys that can be used to set a group of types at once are:

- ‘all’: sets all types
- ‘int_kind’: sets ‘int’
- ‘float_kind’: sets ‘float’ and ‘longfloat’
- ‘complex_kind’: sets ‘complexfloat’ and ‘longcomplexfloat’

- `'str_kind'`: sets `'numpystr'`

threshold

[int, optional] Total number of array elements which trigger summarization rather than full repr. Defaults to `numpy.get_printoptions()['threshold']`.

edgeitems

[int, optional] Number of array items in summary at beginning and end of each dimension. Defaults to `numpy.get_printoptions()['edgeitems']`.

sign

[string, either '-', '+', or ' ', optional] Controls printing of the sign of floating-point types. If '+', always print the sign of positive values. If ' ', always prints a space (whitespace character) in the sign position of positive values. If '-', omit the sign character of positive values. Defaults to `numpy.get_printoptions()['sign']`.

Changed in version 2.0: The sign parameter can now be an integer type, previously types were floating-point types.

floatmode

[str, optional] Controls the interpretation of the *precision* option for floating-point types. Defaults to `numpy.get_printoptions()['floatmode']`. Can take the following values:

- `'fixed'`: Always print exactly *precision* fractional digits, even if this would print more or fewer digits than necessary to specify the value uniquely.
- `'unique'`: Print the minimum number of fractional digits necessary to represent each value uniquely. Different elements may have a different number of digits. The value of the *precision* option is ignored.
- `'maxprec'`: Print at most *precision* fractional digits, but if an element can be uniquely represented with fewer digits only print it with that many.
- `'maxprec_equal'`: Print at most *precision* fractional digits, but if every element in the array can be uniquely represented with an equal number of fewer digits, use that many digits for all elements.

legacy

[string or *False*, optional] If set to the string `'1.13'` enables 1.13 legacy printing mode. This approximates numpy 1.13 print output by including a space in the sign position of floats and different behavior for 0d arrays. If set to *False*, disables legacy mode. Unrecognized strings will be ignored with a warning for forward compatibility.

Returns**array_str**

[str] String representation of the array.

Raises**TypeError**

if a callable in *formatter* does not return a string.

See also:

[*array_str*](#), [*array_repr*](#), [*set_printoptions*](#), [*get_printoptions*](#)

Notes

If a formatter is specified for a certain type, the *precision* keyword is ignored for that type.

This is a very flexible function; `array_repr` and `array_str` are using `array2string` internally so keywords with the same name should work identically in all three functions.

Examples

```
>>> import numpy as np
>>> x = np.array([1e-16, 1, 2, 3])
>>> np.array2string(x, precision=2, separator=',',
...                 suppress_small=True)
'[0., 1., 2., 3.]'
```

```
>>> x = np.arange(3.)
>>> np.array2string(x, formatter={'float_kind': lambda x: "%.2f" % x})
'[0.00 1.00 2.00]'
```

```
>>> x = np.arange(3)
>>> np.array2string(x, formatter={'int': lambda x: hex(x)})
'[0x0 0x1 0x2]'
```

`numpy.array_repr` (*arr*, *max_line_width*=None, *precision*=None, *suppress_small*=None)

Return the string representation of an array.

Parameters

arr

[ndarray] Input array.

max_line_width

[int, optional] Inserts newlines if text is longer than *max_line_width*. Defaults to `numpy.get_printoptions() ['linewidth']`.

precision

[int, optional] Floating point precision. Defaults to `numpy.get_printoptions() ['precision']`.

suppress_small

[bool, optional] Represent numbers “very close” to zero as zero; default is False. Very close is defined by precision: if the precision is 8, e.g., numbers smaller (in absolute value) than 5e-9 are represented as zero. Defaults to `numpy.get_printoptions() ['suppress']`.

Returns

string

[str] The string representation of an array.

See also:

[`array\_str`](#), [`array2string`](#), [`set\_printoptions`](#)

Examples

```
>>> import numpy as np
>>> np.array_repr(np.array([1,2]))
'array([1, 2])'
>>> np.array_repr(np.ma.array([0.]))
'MaskedArray([0.])'
>>> np.array_repr(np.array([], np.int32))
'array([], dtype=int32)'
```

```
>>> x = np.array([1e-6, 4e-7, 2, 3])
>>> np.array_repr(x, precision=6, suppress_small=True)
'array([0.000001, 0.          , 2.          , 3.          ])'
```

`numpy.array_str(a, max_line_width=None, precision=None, suppress_small=None)`

Return a string representation of the data in an array.

The data in the array is returned as a single string. This function is similar to `array_repr`, the difference being that `array_repr` also returns information on the kind of array and its data type.

Parameters

a

[ndarray] Input array.

max_line_width

[int, optional] Inserts newlines if text is longer than *max_line_width*. Defaults to `numpy.get_printoptions()['linewidth']`.

precision

[int, optional] Floating point precision. Defaults to `numpy.get_printoptions()['precision']`.

suppress_small

[bool, optional] Represent numbers “very close” to zero as zero; default is False. Very close is defined by precision: if the precision is 8, e.g., numbers smaller (in absolute value) than $5e-9$ are represented as zero. Defaults to `numpy.get_printoptions()['suppress']`.

See also:

[`array2string`](#), [`array\_repr`](#), [`set\_printoptions`](#)

Examples

```
>>> import numpy as np
>>> np.array_str(np.arange(3))
'[0 1 2]'
```

`numpy.format_float_positional(x, precision=None, unique=True, fractional=True, trim='k', sign=False, pad_left=None, pad_right=None, min_digits=None)`

Format a floating-point scalar as a decimal string in positional notation.

Provides control over rounding, trimming and padding. Uses and assumes IEEE unbiased rounding. Uses the “Dragon4” algorithm.

Parameters

x

[python float or numpy floating scalar] Value to format.

precision

[non-negative integer or None, optional] Maximum number of digits to print. May be None if *unique* is *True*, but must be an integer if *unique* is *False*.

unique

[boolean, optional] If *True*, use a digit-generation strategy which gives the shortest representation which uniquely identifies the floating-point number from other values of the same type, by judicious rounding. If *precision* is given fewer digits than necessary can be printed, or if *min_digits* is given more can be printed, in which cases the last digit is rounded with unbiased rounding. If *False*, digits are generated as if printing an infinite-precision value and stopping after *precision* digits, rounding the remaining value with unbiased rounding

fractional

[boolean, optional] If *True*, the cutoffs of *precision* and *min_digits* refer to the total number of digits after the decimal point, including leading zeros. If *False*, *precision* and *min_digits* refer to the total number of significant digits, before or after the decimal point, ignoring leading zeros.

trim

[one of 'k', '.', '0', '-', optional] Controls post-processing trimming of trailing digits, as follows:

- 'k' : keep trailing zeros, keep decimal point (no trimming)
- '.' : trim all trailing zeros, leave decimal point
- '0' : trim all but the zero before the decimal point. Insert the zero if it is missing.
- '-' : trim trailing zeros and any trailing decimal point

sign

[boolean, optional] Whether to show the sign for positive values.

pad_left

[non-negative integer, optional] Pad the left side of the string with whitespace until at least that many characters are to the left of the decimal point.

pad_right

[non-negative integer, optional] Pad the right side of the string with whitespace until at least that many characters are to the right of the decimal point.

min_digits

[non-negative integer or None, optional] Minimum number of digits to print. Only has an effect if *unique=True* in which case additional digits past those necessary to uniquely identify the value may be printed, rounding the last additional digit.

New in version 1.21.0.

Returns

rep

[string] The string representation of the floating point value

See also:

format_float_scientific

Examples

```
>>> import numpy as np
>>> np.format_float_positional(np.float32(np.pi))
'3.1415927'
>>> np.format_float_positional(np.float16(np.pi))
'3.14'
>>> np.format_float_positional(np.float16(0.3))
'0.3'
>>> np.format_float_positional(np.float16(0.3), unique=False, precision=10)
'0.3000488281'
```

`numpy.format_float_scientific(x, precision=None, unique=True, trim='k', sign=False, pad_left=None, exp_digits=None, min_digits=None)`

Format a floating-point scalar as a decimal string in scientific notation.

Provides control over rounding, trimming and padding. Uses and assumes IEEE unbiased rounding. Uses the “Dragon4” algorithm.

Parameters

x

[python float or numpy floating scalar] Value to format.

precision

[non-negative integer or None, optional] Maximum number of digits to print. May be None if *unique* is *True*, but must be an integer if *unique* is *False*.

unique

[boolean, optional] If *True*, use a digit-generation strategy which gives the shortest representation which uniquely identifies the floating-point number from other values of the same type, by judicious rounding. If *precision* is given fewer digits than necessary can be printed. If *min_digits* is given more can be printed, in which cases the last digit is rounded with unbiased rounding. If *False*, digits are generated as if printing an infinite-precision value and stopping after *precision* digits, rounding the remaining value with unbiased rounding

trim

[one of 'k', '.', '0', '-', optional] Controls post-processing trimming of trailing digits, as follows:

- 'k': keep trailing zeros, keep decimal point (no trimming)
- '.': trim all trailing zeros, leave decimal point
- '0': trim all but the zero before the decimal point. Insert the zero if it is missing.
- '-': trim trailing zeros and any trailing decimal point

sign

[boolean, optional] Whether to show the sign for positive values.

pad_left

[non-negative integer, optional] Pad the left side of the string with whitespace until at least that many characters are to the left of the decimal point.

exp_digits

[non-negative integer, optional] Pad the exponent with zeros until it contains at least this many digits. If omitted, the exponent will be at least 2 digits.

min_digits

[non-negative integer or None, optional] Minimum number of digits to print. This only has an

effect for `unique=True`. In that case more digits than necessary to uniquely identify the value may be printed and rounded unbiased.

New in version 1.21.0.

Returns

rep

[string] The string representation of the floating point value

See also:

`format_float_positional`

Examples

```
>>> import numpy as np
>>> np.format_float_scientific(np.float32(np.pi))
'3.1415927e+00'
>>> s = np.float32(1.23e24)
>>> np.format_float_scientific(s, unique=False, precision=15)
'1.230000071797338e+24'
>>> np.format_float_scientific(s, exp_digits=4)
'1.23e+0024'
```

Memory mapping files

<code>memmap(filename[, dtype, mode, offset, ...])</code>	Create a memory-map to an array stored in a <i>binary</i> file on disk.
<code>lib.format.open_memmap(filename[, mode, ...])</code>	Open a .npy file as a memory-mapped array.

Text formatting options

Text formatting settings are maintained in a `context variable`, allowing different threads or async tasks to have independent configurations. For more information, see *Thread Safety*.

<code>set_printoptions([precision, threshold, ...])</code>	Set printing options.
<code>get_printoptions()</code>	Return the current print options.
<code>printoptions(*args, **kwargs)</code>	Context manager for setting print options.

`numpy.set_printoptions` (*precision=None, threshold=None, edgeitems=None, linewidth=None, suppress=None, nanstr=None, infstr=None, formatter=None, sign=None, floatmode=None, *, legacy=None, override_repr=None*)

Set printing options.

These options determine the way floating point numbers, arrays and other NumPy objects are displayed.

Parameters

precision

[int or None, optional] Number of digits of precision for floating point output (default 8). May

be None if *floatmode* is not *fixed*, to print as many digits as necessary to uniquely specify the value.

threshold

[int, optional] Total number of array elements which trigger summarization rather than full repr (default 1000). To always use the full repr without summarization, pass `sys.maxsize`.

edgeitems

[int, optional] Number of array items in summary at beginning and end of each dimension (default 3).

linewidth

[int, optional] The number of characters per line for the purpose of inserting line breaks (default 75).

suppress

[bool, optional] If True, always print floating point numbers using fixed point notation, in which case numbers equal to zero in the current precision will print as zero. If False, then scientific notation is used when absolute value of the smallest number is $< 1e-4$ or the ratio of the maximum absolute value to the minimum is $> 1e3$. The default is False.

nanstr

[str, optional] String representation of floating point not-a-number (default nan).

infstr

[str, optional] String representation of floating point infinity (default inf).

sign

[string, either '-', '+', or ' ', optional] Controls printing of the sign of floating-point types. If '+', always print the sign of positive values. If ' ', always prints a space (whitespace character) in the sign position of positive values. If '-', omit the sign character of positive values. (default '-')

Changed in version 2.0: The sign parameter can now be an integer type, previously types were floating-point types.

formatter

[dict of callables, optional] If not None, the keys should indicate the type(s) that the respective formatting function applies to. Callables should return a string. Types that are not specified (by their corresponding keys) are handled by the default formatters. Individual types for which a formatter can be set are:

- 'bool'
- 'int'
- 'timedelta' : a `numpy.timedelta64`
- 'datetime' : a `numpy.datetime64`
- 'float'
- 'longfloat' : 128-bit floats
- 'complexfloat'
- 'longcomplexfloat' : composed of two 128-bit floats
- 'numpystr' : types `numpy.bytes_` and `numpy.str_`
- 'object' : `np.object_` arrays

Other keys that can be used to set a group of types at once are:

- 'all' : sets all types
- 'int_kind' : sets 'int'
- 'float_kind' : sets 'float' and 'longfloat'
- 'complex_kind' : sets 'complexfloat' and 'longcomplexfloat'
- 'str_kind' : sets 'numpystr'

floatmode

[str, optional] Controls the interpretation of the *precision* option for floating-point types. Can take the following values (default `maxprec_equal`):

- **'fixed': Always print exactly *precision* fractional digits,**
even if this would print more or fewer digits than necessary to specify the value uniquely.
- **'unique': Print the minimum number of fractional digits necessary**
to represent each value uniquely. Different elements may have a different number of digits. The value of the *precision* option is ignored.
- **'maxprec': Print at most *precision* fractional digits, but if**
an element can be uniquely represented with fewer digits only print it with that many.
- **'maxprec_equal': Print at most *precision* fractional digits,**
but if every element in the array can be uniquely represented with an equal number of fewer digits, use that many digits for all elements.

legacy

[string or *False*, optional] If set to the string '1.13' enables 1.13 legacy printing mode. This approximates numpy 1.13 print output by including a space in the sign position of floats and different behavior for 0d arrays. This also enables 1.21 legacy printing mode (described below).

If set to the string '1.21' enables 1.21 legacy printing mode. This approximates numpy 1.21 print output of complex structured dtypes by not inserting spaces after commas that separate fields and after colons.

If set to '1.25' approximates printing of 1.25 which mainly means that numeric scalars are printed without their type information, e.g. as `3.0` rather than `np.float64(3.0)`.

If set to '2.1', shape information is not given when arrays are summarized (i.e., multiple elements replaced with `...`).

If set to '2.2', the transition to use scientific notation for printing `np.float16` and `np.float32` types may happen later or not at all for larger values.

If set to *False*, disables legacy mode.

Unrecognized strings will be ignored with a warning for forward compatibility.

Changed in version 1.22.0.

Changed in version 2.2.

override_repr: callable, optional

If set a passed function will be used for generating arrays' repr. Other options will be ignored.

See also:

[*get_printoptions*](#), [*printoptions*](#), [*array2string*](#)

Notes

- formatter is always reset with a call to `set_printoptions`.
- Use `printoptions` as a context manager to set the values temporarily.
- These print options apply only to NumPy ndarrays, not to scalars.

Concurrency note: see *Text formatting options*

Examples

Floating point precision can be set:

```
>>> import numpy as np
>>> np.set_printoptions(precision=4)
>>> np.array([1.123456789])
[1.1235]
```

Long arrays can be summarised:

```
>>> np.set_printoptions(threshold=5)
>>> np.arange(10)
array([0, 1, 2, ..., 7, 8, 9], shape=(10,))
```

Small results can be suppressed:

```
>>> eps = np.finfo(float).eps
>>> x = np.arange(4.)
>>> x**2 - (x + eps)**2
array([-4.9304e-32, -4.4409e-16,  0.0000e+00,  0.0000e+00])
>>> np.set_printoptions(suppress=True)
>>> x**2 - (x + eps)**2
array([-0., -0.,  0.,  0.])
```

A custom formatter can be used to display array elements as desired:

```
>>> np.set_printoptions(formatter={'all':lambda x: 'int: '+str(-x)})
>>> x = np.arange(3)
>>> x
array([int: 0, int: -1, int: -2])
>>> np.set_printoptions() # formatter gets reset
>>> x
array([0, 1, 2])
```

To put back the default options, you can use:

```
>>> np.set_printoptions(edgeitems=3, infstr='inf',
... linewidth=75, nanstr='nan', precision=8,
... suppress=False, threshold=1000, formatter=None)
```

Also to temporarily override options, use `printoptions` as a context manager:

```
>>> with np.printoptions(precision=2, suppress=True, threshold=5):
...     np.linspace(0, 10, 10)
array([ 0. ,  1.11,  2.22, ...,  7.78,  8.89, 10. ], shape=(10,))
```

`numpy.get_printoptions()`

Return the current print options.

Returns

print_opts

[dict] Dictionary of current print options with keys

- precision : int
- threshold : int
- edgeitems : int
- linewidth : int
- suppress : bool
- nanstr : str
- infstr : str
- sign : str
- formatter : dict of callables
- floatmode : str
- legacy : str or False

For a full description of these options, see [set_printoptions](#).

See also:

[set_printoptions](#), [printoptions](#)

Notes

These print options apply only to NumPy ndarrays, not to scalars.

Concurrency note: see [Text formatting options](#)

Examples

```
>>> import numpy as np
```

```
>>> np.get_printoptions()
{'edgeitems': 3, 'threshold': 1000, ..., 'override_repr': None}
```

```
>>> np.get_printoptions()['linewidth']
75
>>> np.set_printoptions(linewidth=100)
>>> np.get_printoptions()['linewidth']
100
```

`numpy.printoptions(*args, **kwargs)`

Context manager for setting print options.

Set print options for the scope of the *with* block, and restore the old options at the end. See [set_printoptions](#) for the full description of available options.

See also:

set_printoptions, get_printoptions

Notes

These print options apply only to NumPy ndarrays, not to scalars.

Concurrency note: see *Text formatting options*

Examples

```
>>> import numpy as np
```

```
>>> from numpy.testing import assert_equal
>>> with np.printoptions(precision=2):
...     np.array([2.0]) / 3
array([0.67])
```

The *as*-clause of the *with*-statement gives the current print options:

```
>>> with np.printoptions(precision=2) as opts:
...     assert_equal(opts, np.get_printoptions())
```

Base-n representations

<code>binary_repr(num[, width])</code>	Return the binary representation of the input number as a string.
<code>base_repr(number[, base, padding])</code>	Return a string representation of a number in the given base system.

`numpy.base_repr` (*number*, *base*=2, *padding*=0)

Return a string representation of a number in the given base system.

Parameters

number

[int] The value to convert. Positive and negative values are handled.

base

[int, optional] Convert *number* to the *base* number system. The valid range is 2-36, the default value is 2.

padding

[int, optional] Number of zeros padded on the left. Default is 0 (no padding).

Returns

out

[str] String representation of *number* in *base* system.

See also:

binary_repr

Faster version of *base_repr* for base 2.

Examples

```
>>> import numpy as np
>>> np.base_repr(5)
'101'
>>> np.base_repr(6, 5)
'11'
>>> np.base_repr(7, base=5, padding=3)
'00012'
```

```
>>> np.base_repr(10, base=16)
'A'
>>> np.base_repr(32, base=16)
'20'
```

Data sources

<code>lib.npyio.DataSource([destpath])</code>	A generic data source file (file, http, ftp, ...).
---	--

Binary format description

<code>lib.format</code>	Binary serialization
-------------------------	----------------------

1.4.10 Indexing routines**See also:**

basics.indexing

Generating index arrays

<code>c_</code>	Translates slice objects to concatenation along the second axis.
<code>r_</code>	Translates slice objects to concatenation along the first axis.
<code>s_</code>	A nicer way to build up index tuples for arrays.
<code>nonzero(a)</code>	Return the indices of the elements that are non-zero.
<code>where(condition, [x, y], /)</code>	Return elements chosen from <i>x</i> or <i>y</i> depending on <i>condition</i> .
<code>indices(dimensions[, dtype, sparse])</code>	Return an array representing the indices of a grid.
<code>ix_(*args)</code>	Construct an open mesh from multiple sequences.
<code>ogrid</code>	An instance which returns an open multi-dimensional "meshgrid".
<code>ravel_multi_index(multi_index, dims[, mode, ...])</code>	Converts a tuple of index arrays into an array of flat indices, applying boundary modes to the multi-index.
<code>unravel_index(indices, shape[, order])</code>	Converts a flat index or array of flat indices into a tuple of coordinate arrays.
<code>diag_indices(n[, ndim])</code>	Return the indices to access the main diagonal of an array.
<code>diag_indices_from(arr)</code>	Return the indices to access the main diagonal of an <i>n</i> -dimensional array.
<code>mask_indices(n, mask_func[, k])</code>	Return the indices to access (<i>n</i> , <i>n</i>) arrays, given a masking function.
<code>tril_indices(n[, k, m])</code>	Return the indices for the lower-triangle of an (<i>n</i> , <i>m</i>) array.
<code>tril_indices_from(arr[, k])</code>	Return the indices for the lower-triangle of <i>arr</i> .
<code>triu_indices(n[, k, m])</code>	Return the indices for the upper-triangle of an (<i>n</i> , <i>m</i>) array.
<code>triu_indices_from(arr[, k])</code>	Return the indices for the upper-triangle of <i>arr</i> .

`numpy.c_ = <numpy.lib._index_tricks_impl.CClass object>`

Translates slice objects to concatenation along the second axis.

This is short-hand for `np.r_['-1,2,0', index expression]`, which is useful because of its common occurrence. In particular, arrays will be stacked along their last axis after being upgraded to at least 2-D with 1's post-pended to the shape (column vectors made out of 1-D arrays).

See also:

[`column\_stack`](#)

Stack 1-D arrays as columns into a 2-D array.

[`r\_`](#)

For more detailed documentation.

Examples

```
>>> import numpy as np
>>> np.c_[np.array([1,2,3]), np.array([4,5,6])]
array([[1, 4],
       [2, 5],
       [3, 6]])
>>> np.c_[np.array([[1,2,3]]), 0, 0, np.array([[4,5,6]])]
array([[1, 2, 3, ..., 4, 5, 6]])
```

`numpy.r_ = <numpy.lib._index_tricks_impl.RClass object>`

Translates slice objects to concatenation along the first axis.

This is a simple way to build up arrays quickly. There are two use cases.

1. If the index expression contains comma separated arrays, then stack them along their first axis.
2. If the index expression contains slice notation or scalars then create a 1-D array with a range indicated by the slice notation.

If slice notation is used, the syntax `start:stop:step` is equivalent to `np.arange(start, stop, step)` inside of the brackets. However, if `step` is an imaginary number (i.e. `100j`) then its integer portion is interpreted as a number-of-points desired and the start and stop are inclusive. In other words `start:stop:stepj` is interpreted as `np.linspace(start, stop, step, endpoint=1)` inside of the brackets. After expansion of slice notation, all comma separated sequences are concatenated together.

Optional character strings placed as the first element of the index expression can be used to change the output. The strings 'r' or 'c' result in matrix output. If the result is 1-D and 'r' is specified a 1 x N (row) matrix is produced. If the result is 1-D and 'c' is specified, then an N x 1 (column) matrix is produced. If the result is 2-D then both provide the same matrix result.

A string integer specifies which axis to stack multiple comma separated arrays along. A string of two comma-separated integers allows indication of the minimum number of dimensions to force each entry into as the second integer (the axis to concatenate along is still the first integer).

A string with three comma-separated integers allows specification of the axis to concatenate along, the minimum number of dimensions to force the entries to, and which axis should contain the start of the arrays which are less than the specified number of dimensions. In other words the third integer allows you to specify where the 1's should be placed in the shape of the arrays that have their shapes upgraded. By default, they are placed in the front of the shape tuple. The third argument allows you to specify where the start of the array should be instead. Thus, a third argument of '0' would place the 1's at the end of the array shape. Negative integers specify where in the new shape tuple the last dimension of upgraded arrays should be placed, so the default is '-1'.

Parameters

Not a function, so takes no parameters

Returns

A concatenated ndarray or matrix.

See also:

`concatenate`

Join a sequence of arrays along an existing axis.

`c_`

Translates slice objects to concatenation along the second axis.

Examples

```
>>> import numpy as np
>>> np.r_[np.array([1,2,3]), 0, 0, np.array([4,5,6])]
array([1, 2, 3, ..., 4, 5, 6])
>>> np.r_[1:6j, [0]*3, 5, 6]
array([-1. , -0.6, -0.2,  0.2,  0.6,  1. ,  0. ,  0. ,  0. ,  5. ,  6. ])
```

String integers specify the axis to concatenate along or the minimum number of dimensions to force entries into.

```
>>> a = np.array([[0, 1, 2], [3, 4, 5]])
>>> np.r_['-1', a, a] # concatenate along last axis
array([[0, 1, 2, 0, 1, 2],
       [3, 4, 5, 3, 4, 5]])
>>> np.r_['0,2', [1,2,3], [4,5,6]] # concatenate along first axis, dim>=2
array([[1, 2, 3],
       [4, 5, 6]])
```

```
>>> np.r_['0,2,0', [1,2,3], [4,5,6]]
array([[1],
       [2],
       [3],
       [4],
       [5],
       [6]])
>>> np.r_['1,2,0', [1,2,3], [4,5,6]]
array([[1, 4],
       [2, 5],
       [3, 6]])
```

Using 'r' or 'c' as a first string argument creates a matrix.

```
>>> np.r_['r', [1,2,3], [4,5,6]]
matrix([[1, 2, 3, 4, 5, 6]])
```

`numpy.s_ = <numpy.lib._index_tricks_impl.IndexExpression object>`

A nicer way to build up index tuples for arrays.

Note: Use one of the two predefined instances `index_exp` or `s_` rather than directly using `IndexExpression`.

For any index combination, including slicing and axis insertion, `a[indices]` is the same as `a[np.index_exp[indices]]` for any array *a*. However, `np.index_exp[indices]` can be used anywhere in Python code and returns a tuple of slice objects that can be used in the construction of complex index expressions.

Parameters

maketuple

[bool] If True, always returns a tuple.

See also:

s_

Predefined instance without tuple conversion: `s_ = IndexExpression(maketuple=False)`. The `index_exp` is another predefined instance that always returns a tuple: `index_exp = IndexExpression(maketuple=True)`.

Notes

You can do all this with `slice` plus a few special objects, but there's a lot to remember and this version is simpler because it uses the standard array indexing syntax.

Examples

```
>>> import numpy as np
>>> np.s_[2::2]
slice(2, None, 2)
>>> np.index_exp[2::2]
(slice(2, None, 2),)
```

```
>>> np.array([0, 1, 2, 3, 4])[np.s_[2::2]]
array([2, 4])
```

`numpy.nonzero(a)`

Return the indices of the elements that are non-zero.

Returns a tuple of arrays, one for each dimension of *a*, containing the indices of the non-zero elements in that dimension. The values in *a* are always tested and returned in row-major, C-style order.

To group the indices by element, rather than dimension, use *argwhere*, which returns a row for each non-zero element.

Parameters

a
[array_like] Input array.

Returns

tuple_of_arrays
[tuple] Indices of elements that are non-zero.

See also:

flatnonzero

Return indices that are non-zero in the flattened version of the input array.

ndarray.nonzero

Equivalent ndarray method.

count_nonzero

Counts the number of non-zero elements in the input array.

Notes

While the nonzero values can be obtained with `a[nonzero(a)]`, it is recommended to use `x[x.astype(np.bool)]` or `x[x != 0]` instead, which will correctly handle 0-d arrays.

Examples

```
>>> import numpy as np
>>> x = np.array([[3, 0, 0], [0, 4, 0], [5, 6, 0]])
>>> x
array([[3, 0, 0],
       [0, 4, 0],
       [5, 6, 0]])
>>> np.nonzero(x)
(array([0, 1, 2, 2]), array([0, 1, 0, 1]))
```

```
>>> x[np.nonzero(x)]
array([3, 4, 5, 6])
>>> np.transpose(np.nonzero(x))
array([[0, 0],
       [1, 1],
       [2, 0],
       [2, 1]])
```

A common use for `nonzero` is to find the indices of an array, where a condition is `True`. Given an array *a*, the condition *a* > 3 is a boolean array and since `False` is interpreted as 0, `np.nonzero(a > 3)` yields the indices of the *a* where the condition is true.

```
>>> a = np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
>>> a > 3
array([[False, False, False],
       [ True,  True,  True],
       [ True,  True,  True]])
>>> np.nonzero(a > 3)
(array([1, 1, 1, 2, 2, 2]), array([0, 1, 2, 0, 1, 2]))
```

Using this result to index *a* is equivalent to using the mask directly:

```
>>> a[np.nonzero(a > 3)]
array([4, 5, 6, 7, 8, 9])
>>> a[a > 3] # prefer this spelling
array([4, 5, 6, 7, 8, 9])
```

`nonzero` can also be called as a method of the array.

```
>>> (a > 3).nonzero()
(array([1, 1, 1, 2, 2, 2]), array([0, 1, 2, 0, 1, 2]))
```

`numpy.where(condition, [x, y, ]/)`

Return elements chosen from *x* or *y* depending on *condition*.

Note: When only *condition* is provided, this function is a shorthand for `np.asarray(condition).nonzero()`. Using *nonzero* directly should be preferred, as it behaves correctly for subclasses. The rest of this documentation covers only the case where all three arguments are provided.

Parameters

condition

[array_like, bool] Where `True`, yield *x*, otherwise yield *y*.

x, y

[array_like] Values from which to choose. *x*, *y* and *condition* need to be broadcastable to some shape.

Returns**out**

[ndarray] An array with elements from *x* where *condition* is True, and elements from *y* elsewhere.

See also:

[*choose*](#)
[*nonzero*](#)

The function that is called when *x* and *y* are omitted

Notes

If all the arrays are 1-D, *where* is equivalent to:

```
[xv if c else yv
 for c, xv, yv in zip(condition, x, y)]
```

Examples

```
>>> import numpy as np
>>> a = np.arange(10)
>>> a
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> np.where(a < 5, a, 10*a)
array([ 0,  1,  2,  3,  4, 50, 60, 70, 80, 90])
```

This can be used on multidimensional arrays too:

```
>>> np.where([[True, False], [True, True]],
...          [[1, 2], [3, 4]],
...          [[9, 8], [7, 6]])
array([[1, 8],
       [3, 4]])
```

The shapes of *x*, *y*, and the condition are broadcast together:

```
>>> x, y = np.ogrid[:3, :4]
>>> np.where(x < y, x, 10 + y) # both x and 10+y are broadcast
array([[10,  0,  0,  0],
       [10, 11,  1,  1],
       [10, 11, 12,  2]])
```

```
>>> a = np.array([[0, 1, 2],
...               [0, 2, 4],
...               [0, 3, 6]])
>>> np.where(a < 4, a, -1) # -1 is broadcast
array([[ 0,  1,  2],
       [ 0,  2, -1],
       [ 0,  3, -1]])
```

`numpy.indices` (*dimensions*, *dtype*=<class 'int'>, *sparse*=False)

Return an array representing the indices of a grid.

Compute an array where the subarrays contain index values 0, 1, ... varying only along the corresponding axis.

Parameters

dimensions

[sequence of ints] The shape of the grid.

dtype

[dtype, optional] Data type of the result.

sparse

[boolean, optional] Return a sparse representation of the grid instead of a dense representation. Default is False.

Returns

grid

[one ndarray or tuple of ndarrays]

If sparse is False:

Returns one array of grid indices, `grid.shape = (len(dimensions),) + tuple(dimensions)`.

If sparse is True:

Returns a tuple of arrays, with `grid[i].shape = (1, ..., 1, dimensions[i], 1, ..., 1)` with `dimensions[i]` in the *i*th place

See also:

[*mgrid*](#), [*ogrid*](#), [*meshgrid*](#)

Notes

The output shape in the dense case is obtained by prepending the number of dimensions in front of the tuple of dimensions, i.e. if *dimensions* is a tuple (*r0*, ..., *rN-1*) of length *N*, the output shape is (*N*, *r0*, ..., *rN-1*).

The subarrays `grid[k]` contains the N-D array of indices along the *k*-th axis. Explicitly:

```
grid[k, i0, i1, ..., iN-1] = ik
```

Examples

```
>>> import numpy as np
>>> grid = np.indices((2, 3))
>>> grid.shape
(2, 2, 3)
>>> grid[0]           # row indices
array([[0, 0, 0],
       [1, 1, 1]])
>>> grid[1]           # column indices
array([[0, 1, 2],
       [0, 1, 2]])
```

The indices can be used as an index into an array.

```
>>> x = np.arange(20).reshape(5, 4)
>>> row, col = np.indices((2, 3))
>>> x[row, col]
array([[0, 1, 2],
       [4, 5, 6]])
```

Note that it would be more straightforward in the above example to extract the required elements directly with `x[:2, :3]`.

If `sparse` is set to `true`, the grid will be returned in a sparse representation.

```
>>> i, j = np.indices((2, 3), sparse=True)
>>> i.shape
(2, 1)
>>> j.shape
(1, 3)
>>> i          # row indices
array([[0],
       [1]])
>>> j          # column indices
array([[0, 1, 2]])
```

`numpy.ix_(*args)`

Construct an open mesh from multiple sequences.

This function takes N 1-D sequences and returns N outputs with N dimensions each, such that the shape is 1 in all but one dimension and the dimension with the non-unit shape value cycles through all N dimensions.

Using `ix_` one can quickly construct index arrays that will index the cross product. `a[np.ix_([1, 3], [2, 5])]` returns the array `[[a[1, 2] a[1, 5]], [a[3, 2] a[3, 5]]]`.

Parameters

args

[1-D sequences] Each sequence should be of integer or boolean type. Boolean sequences will be interpreted as boolean masks for the corresponding dimension (equivalent to passing in `np.nonzero(boolean_sequence)`).

Returns

out

[tuple of ndarrays] N arrays with N dimensions each, with N the number of input sequences. Together these arrays form an open mesh.

See also:

[`ogrid`](#), [`mgrid`](#), [`meshgrid`](#)

Examples

```
>>> import numpy as np
>>> a = np.arange(10).reshape(2, 5)
>>> a
array([[0, 1, 2, 3, 4],
       [5, 6, 7, 8, 9]])
>>> ixgrid = np.ix_([0, 1], [2, 4])
>>> ixgrid
(array([[0],
       [1]]), array([[2, 4]]))
>>> ixgrid[0].shape, ixgrid[1].shape
((2, 1), (1, 2))
>>> a[ixgrid]
array([[2, 4],
       [7, 9]])
```

```
>>> ixgrid = np.ix_([True, True], [2, 4])
>>> a[ixgrid]
array([[2, 4],
       [7, 9]])
>>> ixgrid = np.ix_([True, True], [False, False, True, False, True])
>>> a[ixgrid]
array([[2, 4],
       [7, 9]])
```

numpy.**ravel_multi_index** (*multi_index*, *dims*, *mode*='raise', *order*='C')

Converts a tuple of index arrays into an array of flat indices, applying boundary modes to the multi-index.

Parameters

multi_index

[tuple of array_like] A tuple of integer arrays, one array for each dimension.

dims

[tuple of ints] The shape of array into which the indices from `multi_index` apply.

mode

[{'raise', 'wrap', 'clip'}, optional] Specifies how out-of-bounds indices are handled. Can specify either one mode or a tuple of modes, one mode per index.

- 'raise' – raise an error (default)
- 'wrap' – wrap around
- 'clip' – clip to the range

In 'clip' mode, a negative index which would normally wrap will clip to 0 instead.

order

[{'C', 'F'}, optional] Determines whether the multi-index should be viewed as indexing in row-major (C-style) or column-major (Fortran-style) order.

Returns

raveled_indices

[ndarray] An array of indices into the flattened version of an array of dimensions `dims`.

See also:

[`unravel\_index`](#)

Examples

```
>>> import numpy as np
>>> arr = np.array([[3,6,6],[4,5,1]])
>>> np.ravel_multi_index(arr, (7,6))
array([22, 41, 37])
>>> np.ravel_multi_index(arr, (7,6), order='F')
array([31, 41, 13])
>>> np.ravel_multi_index(arr, (4,6), mode='clip')
array([22, 23, 19])
>>> np.ravel_multi_index(arr, (4,4), mode=('clip','wrap'))
array([12, 13, 13])
```

```
>>> np.ravel_multi_index((3,1,4,1), (6,7,8,9))
1621
```

`numpy.unravel_index` (*indices*, *shape*, *order*='C')

Converts a flat index or array of flat indices into a tuple of coordinate arrays.

Parameters

indices

[array_like] An integer array whose elements are indices into the flattened version of an array of dimensions *shape*. Before version 1.6.0, this function accepted just one index value.

shape

[tuple of ints] The shape of the array to use for unraveling *indices*.

order

['C', 'F'], optional] Determines whether the indices should be viewed as indexing in row-major (C-style) or column-major (Fortran-style) order.

Returns

unraveled_coors

[tuple of ndarray] Each array in the tuple has the same shape as the *indices* array.

See also:

[`ravel\_multi\_index`](#)

Examples

```
>>> import numpy as np
>>> np.unravel_index([22, 41, 37], (7,6))
(array([3, 6, 6]), array([4, 5, 1]))
>>> np.unravel_index([31, 41, 13], (7,6), order='F')
(array([3, 6, 6]), array([4, 5, 1]))
```

```
>>> np.unravel_index(1621, (6,7,8,9))
(3, 1, 4, 1)
```

`numpy.diag_indices` (*n*, *ndim*=2)

Return the indices to access the main diagonal of an array.

This returns a tuple of indices that can be used to access the main diagonal of an array *a* with `a.ndim >= 2` dimensions and shape `(n, n, ..., n)`. For `a.ndim = 2` this is the usual diagonal, for `a.ndim > 2` this is the set of indices to access `a[i, i, ..., i]` for `i = [0..n-1]`.

Parameters

- n**
[int] The size, along each dimension, of the arrays for which the returned indices can be used.
- ndim**
[int, optional] The number of dimensions.

See also:

[*diag_indices_from*](#)

Examples

```
>>> import numpy as np
```

Create a set of indices to access the diagonal of a (4, 4) array:

```
>>> di = np.diag_indices(4)
>>> di
(array([0, 1, 2, 3]), array([0, 1, 2, 3]))
>>> a = np.arange(16).reshape(4, 4)
>>> a
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15]])
>>> a[di] = 100
>>> a
array([[100,  1,  2,  3],
       [ 4, 100,  6,  7],
       [ 8,  9, 100, 11],
       [12, 13, 14, 100]])
```

Now, we create indices to manipulate a 3-D array:

```
>>> d3 = np.diag_indices(2, 3)
>>> d3
(array([0, 1]), array([0, 1]), array([0, 1]))
```

And use it to set the diagonal of an array of zeros to 1:

```
>>> a = np.zeros((2, 2, 2), dtype=np.int_)
>>> a[d3] = 1
>>> a
array([[[1, 0],
       [0, 0]],
       [[0, 0],
       [0, 1]]])
```

`numpy.diag_indices_from(arr)`

Return the indices to access the main diagonal of an n-dimensional array.

See [*diag_indices*](#) for full details.

Parameters

arr
[array, at least 2-D]

See also:

[*diag_indices*](#)

Examples

```
>>> import numpy as np
```

Create a 4 by 4 array.

```
>>> a = np.arange(16).reshape(4, 4)
>>> a
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15]])
```

Get the indices of the diagonal elements.

```
>>> di = np.diag_indices_from(a)
>>> di
(array([0, 1, 2, 3]), array([0, 1, 2, 3]))
```

```
>>> a[di]
array([ 0,  5, 10, 15])
```

This is simply syntactic sugar for [*diag_indices*](#).

```
>>> np.diag_indices(a.shape[0])
(array([0, 1, 2, 3]), array([0, 1, 2, 3]))
```

`numpy.mask\_indices(n, mask_func, k=0)`

Return the indices to access (n, n) arrays, given a masking function.

Assume *mask_func* is a function that, for a square array *a* of size (n, n) with a possible offset argument *k*, when called as *mask_func(a, k)* returns a new array with zeros in certain locations (functions like [*triu*](#) or [*tril*](#) do precisely this). Then this function returns the indices where the non-zero values would be located.

Parameters

n
[int] The returned indices will be valid to access arrays of shape (n, n).

mask_func
[callable] A function whose call signature is similar to that of [*triu*](#), [*tril*](#). That is, *mask_func(x, k)* returns a boolean array, shaped like *x*. *k* is an optional argument to the function.

k
[scalar] An optional argument which is passed through to *mask_func*. Functions like [*triu*](#), [*tril*](#) take a second argument that is interpreted as an offset.

Returns

indices

[tuple of arrays.] The n arrays of indices corresponding to the locations where `mask_func(np.ones((n, n)), k)` is True.

See also:

[`triu`](#), [`tril`](#), [`triu\_indices`](#), [`tril\_indices`](#)

Examples

```
>>> import numpy as np
```

These are the indices that would allow you to access the upper triangular part of any 3x3 array:

```
>>> iu = np.mask_indices(3, np.triu)
```

For example, if a is a 3x3 array:

```
>>> a = np.arange(9).reshape(3, 3)
>>> a
array([[0, 1, 2],
       [3, 4, 5],
       [6, 7, 8]])
>>> a[iu]
array([0, 1, 2, 4, 5, 8])
```

An offset can be passed also to the masking function. This gets us the indices starting on the first diagonal right of the main one:

```
>>> iu1 = np.mask_indices(3, np.triu, 1)
```

with which we now extract only three elements:

```
>>> a[iu1]
array([1, 2, 5])
```

`numpy.tril_indices` (n , $k=0$, $m=None$)

Return the indices for the lower-triangle of an (n, m) array.

Parameters

n

[int] The row dimension of the arrays for which the returned indices will be valid.

k

[int, optional] Diagonal offset (see [`tril`](#) for details).

m

[int, optional] The column dimension of the arrays for which the returned arrays will be valid. By default m is taken equal to n .

Returns

inds

[tuple of arrays] The row and column indices, respectively. The row indices are sorted in non-decreasing order, and the corresponding column indices are strictly increasing for each row.

See also:

[triu_indices](#)

similar function, for upper-triangular.

[mask_indices](#)

generic function accepting an arbitrary mask function.

[tril](#), *[triu](#)*

Examples

```
>>> import numpy as np
```

Compute two different sets of indices to access 4x4 arrays, one for the lower triangular part starting at the main diagonal, and one starting two diagonals further right:

```
>>> il1 = np.tril_indices(4)
>>> il1
(array([0, 1, 1, 2, 2, 2, 3, 3, 3, 3]), array([0, 0, 1, 0, 1, 2, 0, 1, 2, 3]))
```

Note that row indices (first array) are non-decreasing, and the corresponding column indices (second array) are strictly increasing for each row. Here is how they can be used with a sample array:

```
>>> a = np.arange(16).reshape(4, 4)
>>> a
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15]])
```

Both for indexing:

```
>>> a[il1]
array([ 0,  4,  5, ..., 13, 14, 15])
```

And for assigning values:

```
>>> a[il1] = -1
>>> a
array([[ -1,  1,  2,  3],
       [ -1, -1,  6,  7],
       [ -1, -1, -1, 11],
       [ -1, -1, -1, -1]])
```

These cover almost the whole array (two diagonals right of the main one):

```
>>> il2 = np.tril_indices(4, 2)
>>> a[il2] = -10
>>> a
array([[ -10, -10, -10,  3],
       [ -10, -10, -10, -10],
       [ -10, -10, -10, -10],
       [ -10, -10, -10, -10]])
```

`numpy.tril_indices_from(arr, k=0)`

Return the indices for the lower-triangle of `arr`.

See [tril_indices](#) for full details.

Parameters

arr

[array_like] The indices will be valid for square arrays whose dimensions are the same as `arr`.

k

[int, optional] Diagonal offset (see [tril](#) for details).

See also:

[tril_indices](#), [tril](#), [triu_indices_from](#)

Examples

```
>>> import numpy as np
```

Create a 4 by 4 array

```
>>> a = np.arange(16).reshape(4, 4)
>>> a
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15]])
```

Pass the array to get the indices of the lower triangular elements.

```
>>> trili = np.tril_indices_from(a)
>>> trili
(array([0, 1, 1, 2, 2, 2, 3, 3, 3, 3]), array([0, 0, 1, 0, 1, 2, 0, 1, 2, 3]))
```

```
>>> a[trili]
array([ 0,  4,  5,  8,  9, 10, 12, 13, 14, 15])
```

This is syntactic sugar for `tril_indices()`.

```
>>> np.tril_indices(a.shape[0])
(array([0, 1, 1, 2, 2, 2, 3, 3, 3, 3]), array([0, 0, 1, 0, 1, 2, 0, 1, 2, 3]))
```

Use the `k` parameter to return the indices for the lower triangular array up to the `k`-th diagonal.

```
>>> trili1 = np.tril_indices_from(a, k=1)
>>> a[trili1]
array([ 0,  1,  4,  5,  6,  8,  9, 10, 11, 12, 13, 14, 15])
```

`numpy.triu_indices(n, k=0, m=None)`

Return the indices for the upper-triangle of an `(n, m)` array.

Parameters

n

[int] The size of the arrays for which the returned indices will be valid.

k
[int, optional] Diagonal offset (see [triu](#) for details).

m
[int, optional] The column dimension of the arrays for which the returned arrays will be valid.
By default *m* is taken equal to *n*.

Returns

inds
[tuple, shape(2) of ndarrays, shape(*n*)] The row and column indices, respectively. The row indices are sorted in non-decreasing order, and the corresponding column indices are strictly increasing for each row.

See also:

[tril_indices](#)
similar function, for lower-triangular.

[mask_indices](#)
generic function accepting an arbitrary mask function.

[triu](#), [tril](#)

Examples

```
>>> import numpy as np
```

Compute two different sets of indices to access 4x4 arrays, one for the upper triangular part starting at the main diagonal, and one starting two diagonals further right:

```
>>> iu1 = np.triu_indices(4)
>>> iu1
(array([0, 0, 0, 0, 1, 1, 1, 2, 2, 3]), array([0, 1, 2, 3, 1, 2, 3, 2, 3, 3]))
```

Note that row indices (first array) are non-decreasing, and the corresponding column indices (second array) are strictly increasing for each row.

Here is how they can be used with a sample array:

```
>>> a = np.arange(16).reshape(4, 4)
>>> a
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15]])
```

Both for indexing:

```
>>> a[iu1]
array([ 0,  1,  2, ..., 10, 11, 15])
```

And for assigning values:

```
>>> a[iu1] = -1
>>> a
array([[ -1,  -1,  -1,  -1],
       [  4,  -1,  -1,  -1],
```

(continues on next page)

(continued from previous page)

```
[ 8,  9, -1, -1],
 [12, 13, 14, -1]])
```

These cover only a small part of the whole array (two diagonals right of the main one):

```
>>> iu2 = np.triu_indices(4, 2)
>>> a[iu2] = -10
>>> a
array([[ -1,  -1, -10, -10],
       [  4,  -1,  -1, -10],
       [  8,   9,  -1,  -1],
       [ 12,  13,  14,  -1]])
```

`numpy.triu_indices_from(arr, k=0)`

Return the indices for the upper-triangle of `arr`.

See [triu_indices](#) for full details.

Parameters

arr

[ndarray, shape(N, N)] The indices will be valid for square arrays.

k

[int, optional] Diagonal offset (see [triu](#) for details).

Returns

triu_indices_from

[tuple, shape(2) of ndarray, shape(N)] Indices for the upper-triangle of `arr`.

See also:

[triu_indices](#), [triu](#), [tril_indices_from](#)

Examples

```
>>> import numpy as np
```

Create a 4 by 4 array

```
>>> a = np.arange(16).reshape(4, 4)
>>> a
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15]])
```

Pass the array to get the indices of the upper triangular elements.

```
>>> triui = np.triu_indices_from(a)
>>> triui
(array([0, 0, 0, 0, 1, 1, 1, 2, 2, 3]), array([0, 1, 2, 3, 1, 2, 3, 2, 3, 3]))
```

```
>>> a[triui]
array([ 0,  1,  2,  3,  5,  6,  7, 10, 11, 15])
```

This is syntactic sugar for `triu_indices()`.

```
>>> np.triu_indices(a.shape[0])
(array([0, 0, 0, 0, 1, 1, 1, 2, 2, 3]), array([0, 1, 2, 3, 1, 2, 3, 2, 3, 3]))
```

Use the *k* parameter to return the indices for the upper triangular array from the *k*-th diagonal.

```
>>> triuim1 = np.triu_indices_from(a, k=1)
>>> a[triuim1]
array([ 1,  2,  3,  6,  7, 11])
```

Indexing-like operations

<code>take(a, indices[, axis, out, mode])</code>	Take elements from an array along an axis.
<code>take_along_axis(arr, indices[, axis])</code>	Take values from the input array by matching 1d index and data slices.
<code>choose(a, choices[, out, mode])</code>	Construct an array from an index array and a list of arrays to choose from.
<code>compress(condition, a[, axis, out])</code>	Return selected slices of an array along given axis.
<code>diag(v[, k])</code>	Extract a diagonal or construct a diagonal array.
<code>diagonal(a[, offset, axis1, axis2])</code>	Return specified diagonals.
<code>select(condlist, choicelist[, default])</code>	Return an array drawn from elements in choicelist, depending on conditions.

`numpy.take(a, indices, axis=None, out=None, mode='raise')`

Take elements from an array along an axis.

When *axis* is not *None*, this function does the same thing as “fancy” indexing (indexing arrays using arrays); however, it can be easier to use if you need elements along a given axis. A call such as `np.take(arr, indices, axis=3)` is equivalent to `arr[:, :, :, indices, ...]`.

Explained without fancy indexing, this is equivalent to the following use of *ndindex*, which sets each of *ii*, *jj*, and *kk* to a tuple of indices:

```
Ni, Nk = a.shape[:axis], a.shape[axis+1:]
Nj = indices.shape
for ii in ndindex(Ni):
    for jj in ndindex(Nj):
        for kk in ndindex(Nk):
            out[ii + jj + kk] = a[ii + (indices[jj],) + kk]
```

Parameters

a

[array_like (Ni..., M, Nk...)] The source array.

indices

[array_like (Nj...)] The indices of the values to extract. Also allow scalars for indices.

axis

[int, optional] The axis over which to select values. By default, the flattened input array is used.

out

[ndarray, optional (Ni..., Nj..., Nk...)] If provided, the result will be placed in this array. It

should be of the appropriate shape and dtype. Note that *out* is always buffered if *mode*='raise'; use other modes for better performance.

mode

[{'raise', 'wrap', 'clip'}, optional] Specifies how out-of-bounds indices will behave.

- 'raise' – raise an error (default)
- 'wrap' – wrap around
- 'clip' – clip to the range

'clip' mode means that all indices that are too large are replaced by the index that addresses the last element along that axis. Note that this disables indexing with negative numbers.

Returns

out

[ndarray (Ni..., Nj..., Nk...)] The returned array has the same type as *a*.

See also:

compress

Take elements using a boolean mask

ndarray.take

equivalent method

take_along_axis

Take elements by matching the array and the index arrays

Notes

By eliminating the inner loop in the description above, and using *s_* to build simple slice objects, *take* can be expressed in terms of applying fancy indexing to each 1-d slice:

```
Ni, Nk = a.shape[:axis], a.shape[axis+1:]
for ii in ndindex(Ni):
    for kk in ndindex(Nk):
        out[ii + s_[:axis,] + kk] = a[ii + s_[axis,] + kk][indices]
```

For this reason, it is equivalent to (but faster than) the following use of *apply_along_axis*:

```
out = np.apply_along_axis(lambda a_1d: a_1d[indices], axis, a)
```

Examples

```
>>> import numpy as np
>>> a = [4, 3, 5, 7, 6, 8]
>>> indices = [0, 1, 4]
>>> np.take(a, indices)
array([4, 3, 6])
```

In this example if *a* is an ndarray, “fancy” indexing can be used.

```
>>> a = np.array(a)
>>> a[indices]
array([4, 3, 6])
```

If *indices* is not one dimensional, the output also has these dimensions.

```
>>> np.take(a, [[0, 1], [2, 3]])
array([[4, 3],
       [5, 7]])
```

`numpy.take_along_axis` (*arr*, *indices*, *axis=-1*)

Take values from the input array by matching 1d index and data slices.

This iterates over matching 1d slices oriented along the specified axis in the index and data arrays, and uses the former to look up values in the latter. These slices can be different lengths.

Functions returning an index along an axis, like *argsort* and *argpartition*, produce suitable indices for this function.

Parameters

arr

[ndarray (Ni..., M, Nk...)] Source array

indices

[ndarray (Ni..., J, Nk...)] Indices to take along each 1d slice of *arr*. This must match the dimension of *arr*, but dimensions Ni and Nj only need to broadcast against *arr*.

axis

[int or None, optional] The axis to take 1d slices along. If *axis* is None, the input array is treated as if it had first been flattened to 1d, for consistency with *sort* and *argsort*.

Changed in version 2.3: The default value is now -1.

Returns

out: ndarray (Ni..., J, Nk...)

The indexed result.

See also:

take

Take along an axis, using the same indices for every 1d slice

put_along_axis

Put values into the destination array by matching 1d index and data slices

Notes

This is equivalent to (but faster than) the following use of *ndindex* and *s_*, which sets each of *ii* and *kk* to a tuple of indices:

```
Ni, M, Nk = a.shape[:axis], a.shape[axis], a.shape[axis+1:]
J = indices.shape[axis] # Need not equal M
out = np.empty(Ni + (J,) + Nk)

for ii in ndindex(Ni):
    for kk in ndindex(Nk):
        a_1d = a[ii + s_[:,] + kk]
        indices_1d = indices[ii + s_[:,] + kk]
        out_1d = out[ii + s_[:,] + kk]
        for j in range(J):
            out_1d[j] = a_1d[indices_1d[j]]
```

Equivalently, eliminating the inner loop, the last two lines would be:

```
out_1d[:] = a_1d[indices_1d]
```

Examples

```
>>> import numpy as np
```

For this sample array

```
>>> a = np.array([[10, 30, 20], [60, 40, 50]])
```

We can sort either by using sort directly, or argsort and this function

```
>>> np.sort(a, axis=1)
array([[10, 20, 30],
       [40, 50, 60]])
>>> ai = np.argsort(a, axis=1)
>>> ai
array([[0, 2, 1],
       [1, 2, 0]])
>>> np.take_along_axis(a, ai, axis=1)
array([[10, 20, 30],
       [40, 50, 60]])
```

The same works for max and min, if you maintain the trivial dimension with keepdims:

```
>>> np.max(a, axis=1, keepdims=True)
array([[30],
       [60]])
>>> ai = np.argmax(a, axis=1, keepdims=True)
>>> ai
array([[1],
       [0]])
>>> np.take_along_axis(a, ai, axis=1)
array([[30],
       [60]])
```

If we want to get the max and min at the same time, we can stack the indices first

```
>>> ai_min = np.argmin(a, axis=1, keepdims=True)
>>> ai_max = np.argmax(a, axis=1, keepdims=True)
>>> ai = np.concatenate([ai_min, ai_max], axis=1)
>>> ai
array([[0, 1],
       [1, 0]])
>>> np.take_along_axis(a, ai, axis=1)
array([[10, 30],
       [40, 60]])
```

`numpy.choose` (*a*, *choices*, *out=None*, *mode='raise'*)

Construct an array from an index array and a list of arrays to choose from.

First of all, if confused or uncertain, definitely look at the Examples - in its full generality, this function is less simple than it might seem from the following code description:

```
np.choose(a, c) == np.array([c[a[I]][I] for I in np.ndindex(a.shape)])
```

But this omits some subtleties. Here is a fully general summary:

Given an “index” array (*a*) of integers and a sequence of *n* arrays (*choices*), *a* and each choice array are first broadcast, as necessary, to arrays of a common shape; calling these *Ba* and *Bchoices[i]*, *i* = 0,...,*n*-1 we have that, necessarily, *Ba.shape* == *Bchoices[i].shape* for each *i*. Then, a new array with shape *Ba.shape* is created as follows:

- if *mode*='raise' (the default), then, first of all, each element of *a* (and thus *Ba*) must be in the range [0, *n*-1]; now, suppose that *i* (in that range) is the value at the (*j*₀, *j*₁, ..., *j*_m) position in *Ba* - then the value at the same position in the new array is the value in *Bchoices[i]* at that same position;
- if *mode*='wrap', values in *a* (and thus *Ba*) may be any (signed) integer; modular arithmetic is used to map integers outside the range [0, *n*-1] back into that range; and then the new array is constructed as above;
- if *mode*='clip', values in *a* (and thus *Ba*) may be any (signed) integer; negative integers are mapped to 0; values greater than *n*-1 are mapped to *n*-1; and then the new array is constructed as above.

Parameters

a

[int array] This array must contain integers in [0, *n*-1], where *n* is the number of choices, unless *mode*=wrap or *mode*=clip, in which cases any integers are permissible.

choices

[sequence of arrays] Choice arrays. *a* and all of the choices must be broadcastable to the same shape. If *choices* is itself an array (not recommended), then its outermost dimension (i.e., the one corresponding to *choices.shape*[0]) is taken as defining the “sequence”.

out

[array, optional] If provided, the result will be inserted into this array. It should be of the appropriate shape and dtype. Note that *out* is always buffered if *mode*='raise'; use other modes for better performance.

mode

[{'raise' (default), 'wrap', 'clip'}, optional] Specifies how indices outside [0, *n*-1] will be treated:

- 'raise': an exception is raised
- 'wrap': value becomes value mod *n*
- 'clip': values < 0 are mapped to 0, values > *n*-1 are mapped to *n*-1

Returns

merged_array

[array] The merged result.

Raises

ValueError: shape mismatch

If *a* and each choice array are not all broadcastable to the same shape.

See also:

[*ndarray.choose*](#)

equivalent method

`numpy.take_along_axis`

Preferable if *choices* is an array

Notes

To reduce the chance of misinterpretation, even though the following “abuse” is nominally supported, *choices* should neither be, nor be thought of as, a single array, i.e., the outermost sequence-like container should be either a list or a tuple.

Examples

```
>>> import numpy as np
>>> choices = [[0, 1, 2, 3], [10, 11, 12, 13],
...            [20, 21, 22, 23], [30, 31, 32, 33]]
>>> np.choose([2, 3, 1, 0], choices)
... # the first element of the result will be the first element of the
... # third (2+1) "array" in choices, namely, 20; the second element
... # will be the second element of the fourth (3+1) choice array, i.e.,
... # 31, etc.
... )
array([20, 31, 12,  3])
>>> np.choose([2, 4, 1, 0], choices, mode='clip') # 4 goes to 3 (4-1)
array([20, 31, 12,  3])
>>> # because there are 4 choice arrays
>>> np.choose([2, 4, 1, 0], choices, mode='wrap') # 4 goes to (4 mod 4)
array([20,  1, 12,  3])
>>> # i.e., 0
```

A couple examples illustrating how choose broadcasts:

```
>>> a = [[1, 0, 1], [0, 1, 0], [1, 0, 1]]
>>> choices = [-10, 10]
>>> np.choose(a, choices)
array([[ 10, -10,  10],
       [-10,  10, -10],
       [ 10, -10,  10]])
```

```
>>> # With thanks to Anne Archibald
>>> a = np.array([0, 1]).reshape((2,1,1))
>>> c1 = np.array([1, 2, 3]).reshape((1,3,1))
>>> c2 = np.array([-1, -2, -3, -4, -5]).reshape((1,1,5))
>>> np.choose(a, (c1, c2)) # result is 2x3x5, res[0,:,:]=c1, res[1,:,:]=c2
array([[[ 1,  1,  1,  1,  1],
        [ 2,  2,  2,  2,  2],
        [ 3,  3,  3,  3,  3]],
       [[-1, -2, -3, -4, -5],
        [-1, -2, -3, -4, -5],
        [-1, -2, -3, -4, -5]])
```

`numpy.compress` (*condition*, *a*, *axis=None*, *out=None*)

Return selected slices of an array along given axis.

When working along a given axis, a slice along that axis is returned in *output* for each index where *condition* evaluates to True. When working on a 1-D array, *compress* is equivalent to *extract*.

Parameters

condition

[1-D array of bools] Array that selects which entries to return. If `len(condition)` is less than the size of *a* along the given axis, then output is truncated to the length of the condition array.

a

[array_like] Array from which to extract a part.

axis

[int, optional] Axis along which to take slices. If None (default), work on the flattened array.

out

[ndarray, optional] Output array. Its type is preserved and it must be of the right shape to hold the output.

Returns**compressed_array**

[ndarray] A copy of *a* without the slices along axis for which *condition* is false.

See also:

[*take, choose, diag, diagonal, select*](#)
[*ndarray.compress*](#)

Equivalent method in ndarray

[*extract*](#)

Equivalent method when working on 1-D arrays

ufuncs-output-type**Examples**

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, 4], [5, 6]])
>>> a
array([[1, 2],
       [3, 4],
       [5, 6]])
>>> np.compress([0, 1], a, axis=0)
array([[3, 4]])
>>> np.compress([False, True, True], a, axis=0)
array([[3, 4],
       [5, 6]])
>>> np.compress([False, True], a, axis=1)
array([[2],
       [4],
       [6]])
```

Working on the flattened array does not return slices along an axis but selects elements.

```
>>> np.compress([False, True], a)
array([2])
```

`numpy.select` (*condlist, choicelist, default=0*)

Return an array drawn from elements in *choicelist*, depending on conditions.

Parameters

condlist

[list of bool ndarrays] The list of conditions which determine from which array in *choicelist* the output elements are taken. When multiple conditions are satisfied, the first one encountered in *condlist* is used.

choicelist

[list of ndarrays] The list of arrays from which the output elements are taken. It has to be of the same length as *condlist*.

default

[array_like, optional] The element inserted in *output* when all conditions evaluate to False.

Returns**output**

[ndarray] The output at position *m* is the *m*-th element of the array in *choicelist* where the *m*-th element of the corresponding array in *condlist* is True.

See also:*where*

Return elements from one of two arrays depending on condition.

take, choose, compress, diag, diagonal

Examples

```
>>> import numpy as np
```

Beginning with an array of integers from 0 to 5 (inclusive), elements less than 3 are negated, elements greater than 3 are squared, and elements not meeting either of these conditions (exactly 3) are replaced with a *default* value of 42.

```
>>> x = np.arange(6)
>>> condlist = [x<3, x>3]
>>> choicelist = [-x, x**2]
>>> np.select(condlist, choicelist, 42)
array([ 0, -1, -2, 42, 16, 25])
```

When multiple conditions are satisfied, the first one encountered in *condlist* is used.

```
>>> condlist = [x<=4, x>3]
>>> choicelist = [x, x**2]
>>> np.select(condlist, choicelist, 55)
array([ 0,  1,  2,  3,  4, 25])
```

Inserting data into arrays

<code>place(arr, mask, vals)</code>	Change elements of an array based on conditional and input values.
<code>put(a, ind, v[, mode])</code>	Replaces specified elements of an array with given values.
<code>put_along_axis(arr, indices, values, axis)</code>	Put values into the destination array by matching 1d index and data slices.
<code>putmask(a, /, mask, values)</code>	Changes elements of an array based on conditional and input values.
<code>fill_diagonal(a, val[, wrap])</code>	Fill the main diagonal of the given array of any dimensionality.

`numpy.place(arr, mask, vals)`

Change elements of an array based on conditional and input values.

Similar to `np.copyto(arr, vals, where=mask)`, the difference is that *place* uses the first N elements of *vals*, where N is the number of True values in *mask*, while *copyto* uses the elements where *mask* is True.

Note that *extract* does the exact opposite of *place*.

Parameters

arr

[ndarray] Array to put data into.

mask

[array_like] Boolean mask array. Must have the same size as *arr*.

vals

[1-D sequence] Values to put into *arr*. Only the first N elements are used, where N is the number of True values in *mask*. If *vals* is smaller than N, it will be repeated, and if elements of *arr* are to be masked, this sequence must be non-empty.

See also:

copyto, *put*, *take*, *extract*

Examples

```
>>> import numpy as np
>>> arr = np.arange(6).reshape(2, 3)
>>> np.place(arr, arr>2, [44, 55])
>>> arr
array([[ 0,  1,  2],
       [44, 55, 44]])
```

`numpy.put(a, ind, v, mode='raise')`

Replaces specified elements of an array with given values.

The indexing works on the flattened target array. *put* is roughly equivalent to:

```
a.flat[ind] = v
```

Parameters

a
[ndarray] Target array.

ind
[array_like] Target indices, interpreted as integers.

v
[array_like] Values to place in *a* at target indices. If *v* is shorter than *ind* it will be repeated as necessary.

mode
[{'raise', 'wrap', 'clip'}, optional] Specifies how out-of-bounds indices will behave.

- 'raise' – raise an error (default)
- 'wrap' – wrap around
- 'clip' – clip to the range

'clip' mode means that all indices that are too large are replaced by the index that addresses the last element along that axis. Note that this disables indexing with negative numbers. In 'raise' mode, if an exception occurs the target array may still be modified.

See also:

[*putmask*](#), [*place*](#)

[*put_along_axis*](#)

Put elements by matching the array and the index arrays

Examples

```
>>> import numpy as np
>>> a = np.arange(5)
>>> np.put(a, [0, 2], [-44, -55])
>>> a
array([-44,  1, -55,  3,  4])
```

```
>>> a = np.arange(5)
>>> np.put(a, 22, -5, mode='clip')
>>> a
array([ 0,  1,  2,  3, -5])
```

`numpy.put_along_axis` (*arr*, *indices*, *values*, *axis*)

Put values into the destination array by matching 1d index and data slices.

This iterates over matching 1d slices oriented along the specified axis in the index and data arrays, and uses the former to place values into the latter. These slices can be different lengths.

Functions returning an index along an axis, like [*argsort*](#) and [*argpartition*](#), produce suitable indices for this function.

Parameters

arr
[ndarray (Ni..., M, Nk...)] Destination array.

indices
[ndarray (Ni..., J, Nk...)] Indices to change along each 1d slice of *arr*. This must match the dimension of *arr*, but dimensions in Ni and Nj may be 1 to broadcast against *arr*.

values

[array_like (Ni..., J, Nk...)] values to insert at those indices. Its shape and dimension are broadcast to match that of *indices*.

axis

[int] The axis to take 1d slices along. If axis is None, the destination array is treated as if a flattened 1d view had been created of it.

See also:

take_along_axis

Take values from the input array by matching 1d index and data slices

Notes

This is equivalent to (but faster than) the following use of *ndindex* and *s_*, which sets each of *ii* and *kk* to a tuple of indices:

```
Ni, M, Nk = a.shape[:axis], a.shape[axis], a.shape[axis+1:]
J = indices.shape[axis] # Need not equal M

for ii in ndindex(Ni):
    for kk in ndindex(Nk):
        a_1d = a [ii + s_[:,] + kk]
        indices_1d = indices[ii + s_[:,] + kk]
        values_1d = values [ii + s_[:,] + kk]
        for j in range(J):
            a_1d[indices_1d[j]] = values_1d[j]
```

Equivalently, eliminating the inner loop, the last two lines would be:

```
a_1d[indices_1d] = values_1d
```

Examples

```
>>> import numpy as np
```

For this sample array

```
>>> a = np.array([[10, 30, 20], [60, 40, 50]])
```

We can replace the maximum values with:

```
>>> ai = np.argmax(a, axis=1, keepdims=True)
>>> ai
array([[1],
       [0]])
>>> np.put_along_axis(a, ai, 99, axis=1)
>>> a
array([[10, 99, 20],
       [99, 40, 50]])
```

`numpy.putmask(a, /, mask, values)`

Changes elements of an array based on conditional and input values.

Sets `a.flat[n] = values[n]` for each `n` where `mask.flat[n]==True`.

If *values* is not the same size as *a* and *mask* then it will repeat. This gives behavior different from `a[mask] = values`.

Parameters

a

[ndarray] Target array.

mask

[array_like] Boolean mask array. It has to be the same shape as *a*.

values

[array_like] Values to put into *a* where *mask* is True. If *values* is smaller than *a* it will be repeated.

See also:

[*place*](#), [*put*](#), [*take*](#), [*copyto*](#)

Examples

```
>>> import numpy as np
>>> x = np.arange(6).reshape(2, 3)
>>> np.putmask(x, x>2, x**2)
>>> x
array([[ 0,  1,  2],
       [ 9, 16, 25]])
```

If *values* is smaller than *a* it is repeated:

```
>>> x = np.arange(5)
>>> np.putmask(x, x>1, [-33, -44])
>>> x
array([ 0,  1, -33, -44, -33])
```

`numpy.fill_diagonal(a, val, wrap=False)`

Fill the main diagonal of the given array of any dimensionality.

For an array *a* with `a.ndim >= 2`, the diagonal is the list of values `a[i, ..., i]` with indices *i* all identical. This function modifies the input array in-place without returning a value.

Parameters

a

[array, at least 2-D.] Array whose diagonal is to be filled in-place.

val

[scalar or array_like] Value(s) to write on the diagonal. If *val* is scalar, the value is written along the diagonal. If array-like, the flattened *val* is written along the diagonal, repeating if necessary to fill all diagonal entries.

wrap

[bool] For tall matrices in NumPy version up to 1.6.2, the diagonal “wrapped” after *N* columns. You can have this behavior with this option. This affects only tall matrices.

See also:

[*diag_indices*](#), [*diag_indices_from*](#)

Notes

This functionality can be obtained via *diag_indices*, but internally this version uses a much faster implementation that never constructs the indices and uses simple slicing.

Examples

```
>>> import numpy as np
>>> a = np.zeros((3, 3), int)
>>> np.fill_diagonal(a, 5)
>>> a
array([[5, 0, 0],
       [0, 5, 0],
       [0, 0, 5]])
```

The same function can operate on a 4-D array:

```
>>> a = np.zeros((3, 3, 3, 3), int)
>>> np.fill_diagonal(a, 4)
```

We only show a few blocks for clarity:

```
>>> a[0, 0]
array([[4, 0, 0],
       [0, 0, 0],
       [0, 0, 0]])
>>> a[1, 1]
array([[0, 0, 0],
       [0, 4, 0],
       [0, 0, 0]])
>>> a[2, 2]
array([[0, 0, 0],
       [0, 0, 0],
       [0, 0, 4]])
```

The wrap option affects only tall matrices:

```
>>> # tall matrices no wrap
>>> a = np.zeros((5, 3), int)
>>> np.fill_diagonal(a, 4)
>>> a
array([[4, 0, 0],
       [0, 4, 0],
       [0, 0, 4],
       [0, 0, 0],
       [0, 0, 0]])
```

```
>>> # tall matrices wrap
>>> a = np.zeros((5, 3), int)
>>> np.fill_diagonal(a, 4, wrap=True)
>>> a
array([[4, 0, 0],
       [0, 4, 0],
       [0, 0, 4],
       [0, 0, 0],
       [4, 0, 0]])
```

```
>>> # wide matrices
>>> a = np.zeros((3, 5), int)
>>> np.fill_diagonal(a, 4, wrap=True)
>>> a
array([[4, 0, 0, 0, 0],
       [0, 4, 0, 0, 0],
       [0, 0, 4, 0, 0]])
```

The anti-diagonal can be filled by reversing the order of elements using either `numpy.flipud` or `numpy.fliplr`.

```
>>> a = np.zeros((3, 3), int);
>>> np.fill_diagonal(np.fliplr(a), [1,2,3]) # Horizontal flip
>>> a
array([[0, 0, 1],
       [0, 2, 0],
       [3, 0, 0]])
>>> np.fill_diagonal(np.flipud(a), [1,2,3]) # Vertical flip
>>> a
array([[0, 0, 3],
       [0, 2, 0],
       [1, 0, 0]])
```

Note that the order in which the diagonal is filled varies depending on the flip function.

Iterating over arrays

<code>nditer(op[, flags, op_flags, op_dtypes, ...])</code>	Efficient multi-dimensional iterator object to iterate over arrays.
<code>ndenumerate(arr)</code>	Multidimensional index iterator.
<code>ndindex(*shape)</code>	An N-dimensional iterator object to index arrays.
<code>nested_iters(op, axes[, flags, op_flags, ...])</code>	Create nditers for use in nested loops
<code>flatiter()</code>	Flat iterator object to iterate over arrays.
<code>iterable(y)</code>	Check whether or not an object can be iterated over.

class `numpy.nditer` (*op*, *flags=None*, *op_flags=None*, *op_dtypes=None*, *order='K'*, *casting='safe'*, *op_axes=None*, *itershape=None*, *buffer_size=0*)

Efficient multi-dimensional iterator object to iterate over arrays. To get started using this object, see the [introductory guide to array iteration](#).

Parameters

op

[ndarray or sequence of array_like] The array(s) to iterate over.

flags

[sequence of str, optional] Flags to control the behavior of the iterator.

- `buffered` enables buffering when required.
- `c_index` causes a C-order index to be tracked.
- `f_index` causes a Fortran-order index to be tracked.
- `multi_index` causes a multi-index, or a tuple of indices with one per iteration dimension, to be tracked.

- `common_dtype` causes all the operands to be converted to a common data type, with copying or buffering as necessary.
- `copy_if_overlap` causes the iterator to determine if read operands have overlap with write operands, and make temporary copies as necessary to avoid overlap. False positives (needless copying) are possible in some cases.
- `delay_bufalloc` delays allocation of the buffers until a `reset()` call is made. Allows allocate operands to be initialized before their values are copied into the buffers.
- `external_loop` causes the values given to be one-dimensional arrays with multiple values instead of zero-dimensional arrays.
- `grow_inner` allows the value array sizes to be made larger than the buffer size when both buffered and `external_loop` is used.
- `ranged` allows the iterator to be restricted to a sub-range of the `iterindex` values.
- `refs_ok` enables iteration of reference types, such as object arrays.
- `reduce_ok` enables iteration of `readwrite` operands which are broadcasted, also known as reduction operands.
- `zerosize_ok` allows `itersize` to be zero.

op_flags

[list of list of str, optional] This is a list of flags for each operand. At minimum, one of `readonly`, `readwrite`, or `writenonly` must be specified.

- `readonly` indicates the operand will only be read from.
- `readwrite` indicates the operand will be read from and written to.
- `writenonly` indicates the operand will only be written to.
- `no_broadcast` prevents the operand from being broadcasted.
- `contig` forces the operand data to be contiguous.
- `aligned` forces the operand data to be aligned.
- `nbo` forces the operand data to be in native byte order.
- `copy` allows a temporary read-only copy if required.
- `updateifcopy` allows a temporary read-write copy if required.
- `allocate` causes the array to be allocated if it is `None` in the `op` parameter.
- `no_subtype` prevents an `allocate` operand from using a subtype.
- `arraymask` indicates that this operand is the mask to use for selecting elements when writing to operands with the 'writemasked' flag set. The iterator does not enforce this, but when writing from a buffer back to the array, it only copies those elements indicated by this mask.
- `writemasked` indicates that only elements where the chosen `arraymask` operand is `True` will be written to.
- `overlap_assume_elementwise` can be used to mark operands that are accessed only in the iterator order, to allow less conservative copying when `copy_if_overlap` is present.

op_dtypes

[dtype or tuple of dtype(s), optional] The required data type(s) of the operands. If copying or buffering is enabled, the data will be converted to/from their original types.

order

[['C', 'F', 'A', 'K'], optional] Controls the iteration order. 'C' means C order, 'F' means Fortran order, 'A' means 'F' order if all the arrays are Fortran contiguous, 'C' order otherwise, and 'K' means as close to the order the array elements appear in memory as possible. This also affects the element memory order of `allocate` operands, as they are allocated to be compatible with iteration order. Default is 'K'.

casting

[{'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional] Controls what kind of data casting may occur when making a copy or buffering. Setting this to 'unsafe' is not recommended, as it can adversely affect accumulations.

- 'no' means the data types should not be cast at all.
- 'equiv' means only byte-order changes are allowed.
- 'safe' means only casts which can preserve values are allowed.
- 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed.
- 'unsafe' means any data conversions may be done.

op_axes

[list of list of ints, optional] If provided, is a list of ints or None for each operands. The list of axes for an operand is a mapping from the dimensions of the iterator to the dimensions of the operand. A value of -1 can be placed for entries, causing that dimension to be treated as *newaxis*.

itershape

[tuple of ints, optional] The desired shape of the iterator. This allows `allocate` operands with a dimension mapped by `op_axes` not corresponding to a dimension of a different operand to get a value not equal to 1 for that dimension.

buffersize

[int, optional] When buffering is enabled, controls the size of the temporary buffers. Set to 0 for the default value.

Attributes**dtypes**

[tuple of dtype(s)] The data types of the values provided in `value`. This may be different from the operand data types if buffering is enabled. Valid only before the iterator is closed.

finished

[bool] Whether the iteration over the operands is finished or not.

has_delayed_bufalloc

[bool] If True, the iterator was created with the `delay_bufalloc` flag, and no `reset()` function was called on it yet.

has_index

[bool] If True, the iterator was created with either the `c_index` or the `f_index` flag, and the property `index` can be used to retrieve it.

has_multi_index

[bool] If True, the iterator was created with the `multi_index` flag, and the property `multi_index` can be used to retrieve it.

index

When the `c_index` or `f_index` flag was used, this property provides access to the index. Raises a `ValueError` if accessed and `has_index` is False.

iterationneedsapi

[bool] Whether iteration requires access to the Python API, for example if one of the operands is an object array.

iterindex

[int] An index which matches the order of iteration.

itersize

[int] Size of the iterator.

itviews

Structured view(s) of `operands` in memory, matching the reordered and optimized iterator access pattern. Valid only before the iterator is closed.

multi_index

When the `multi_index` flag was used, this property provides access to the index. Raises a `ValueError` if accessed and `has_multi_index` is `False`.

ndim

[int] The dimensions of the iterator.

nop

[int] The number of iterator operands.

operands

[tuple of operand(s)] `operands[Slice]`

shape

[tuple of ints] Shape tuple, the shape of the iterator.

value

Value of `operands` at current iteration. Normally, this is a tuple of array scalars, but if the flag `external_loop` is used, it is a tuple of one dimensional arrays.

Methods

<code>close()</code>	Resolve all writeback semantics in writeable operands.
<code>copy()</code>	Get a copy of the iterator in its current state.
<code>debug_print()</code>	Print the current state of the <code>nditer</code> instance and debug info to stdout.
<code>enable_external_loop()</code>	When the "external_loop" was not used during construction, but is desired, this modifies the iterator to behave as if the flag was specified.
<code>iternext()</code>	Check whether iterations are left, and perform a single internal iteration without returning the result.
<code>remove_axis(i, /)</code>	Removes axis <i>i</i> from the iterator.
<code>remove_multi_index()</code>	When the "multi_index" flag was specified, this removes it, allowing the internal iteration structure to be optimized further.
<code>reset()</code>	Reset the iterator to its initial state.

method

`nditer.close()`

Resolve all writeback semantics in writeable operands.

See also:

Modifying array values

method

`nditer.copy()`

Get a copy of the iterator in its current state.

Examples

```

>>> import numpy as np
>>> x = np.arange(10)
>>> y = x + 1
>>> it = np.nditer([x, y])
>>> next(it)
(array(0), array(1))
>>> it2 = it.copy()
>>> next(it2)
(array(1), array(2))

```

method

`nditer.debug_print()`

Print the current state of the *nditer* instance and debug info to stdout.

method

`nditer.enable_external_loop()`

When the “external_loop” was not used during construction, but is desired, this modifies the iterator to behave as if the flag was specified.

method

`nditer.itternext()`

Check whether iterations are left, and perform a single internal iteration without returning the result. Used in the C-style pattern do-while pattern. For an example, see *nditer*.

Returns

itternext

[bool] Whether or not there are iterations left.

method

`nditer.remove_axis(i, /)`

Removes axis *i* from the iterator. Requires that the flag “multi_index” be enabled.

method

`nditer.remove_multi_index()`

When the “multi_index” flag was specified, this removes it, allowing the internal iteration structure to be optimized further.

method

`nditer.reset()`

Reset the iterator to its initial state.

Notes

`nditer` supersedes `flatiter`. The iterator implementation behind `nditer` is also exposed by the NumPy C API.

The Python exposure supplies two iteration interfaces, one which follows the Python iterator protocol, and another which mirrors the C-style do-while pattern. The native Python approach is better in most cases, but if you need the coordinates or index of an iterator, use the C-style pattern.

Examples

Here is how we might write an `iter_add` function, using the Python iterator protocol:

```
>>> import numpy as np

>>> def iter_add_py(x, y, out=None):
...     addop = np.add
...     it = np.nditer([x, y, out], [],
...                     [['readonly'], ['readonly'], ['writeonly', 'allocate']])
...     with it:
...         for (a, b, c) in it:
...             addop(a, b, out=c)
...     return it.operands[2]
```

Here is the same function, but following the C-style pattern:

```
>>> def iter_add(x, y, out=None):
...     addop = np.add
...     it = np.nditer([x, y, out], [],
...                     [['readonly'], ['readonly'], ['writeonly', 'allocate']])
...     with it:
...         while not it.finished:
...             addop(it[0], it[1], out=it[2])
...             it.iternext()
...     return it.operands[2]
```

Here is an example outer product function:

```
>>> def outer_it(x, y, out=None):
...     mulop = np.multiply
...     it = np.nditer([x, y, out], ['external_loop'],
...                     [['readonly'], ['readonly'], ['writeonly', 'allocate']],
...                     op_axes=[list(range(x.ndim)) + [-1] * y.ndim,
...                               [-1] * x.ndim + list(range(y.ndim)),
...                               None])
...     with it:
...         for (a, b, c) in it:
...             mulop(a, b, out=c)
...     return it.operands[2]
```

```
>>> a = np.arange(2)+1
>>> b = np.arange(3)+1
>>> outer_it(a,b)
array([[1, 2, 3],
       [2, 4, 6]])
```

Here is an example function which operates like a “lambda” ufunc:

```
>>> def luf(lamdaexpr, *args, **kwargs):
...     '''luf(lamdaexpr, op1, ..., opn, out=None, order='K', casting='safe',
↪bufferize=0)'''
...     nargs = len(args)
...     op = (kwargs.get('out', None),) + args
...     it = np.nditer(op, ['buffered', 'external_loop'],
...                     [['writeonly', 'allocate', 'no_broadcast']] +
...                     [['readonly', 'nbo', 'aligned']] * nargs,
...                     order=kwargs.get('order', 'K'),
...                     casting=kwargs.get('casting', 'safe'),
...                     buffersize=kwargs.get('buffersize', 0))
...     while not it.finished:
...         it[0] = lamdaexpr(*it[1:])
...         it.iternext()
...     return it.operands[0]
```

```
>>> a = np.arange(5)
>>> b = np.ones(5)
>>> luf(lambda i,j:i*i + j/2, a, b)
array([ 0.5,  1.5,  4.5,  9.5, 16.5])
```

If operand flags "writeonly" or "readwrite" are used the operands may be views into the original data with the `WRITEBACKIFCOPY` flag. In this case `nditer` must be used as a context manager or the `nditer.close` method must be called before using the result. The temporary data will be written back to the original data when the `__exit__` function is called but not before:

```
>>> a = np.arange(6, dtype=np.int32)[::-2]
>>> with np.nditer(a, [],
...               [['writeonly', 'updateifcopy']],
...               casting='unsafe',
...               op_dtypes=[np.dtype(np.float32)]) as i:
...     x = i.operands[0]
...     x[:] = [-1, -2, -3]
...     # a still unchanged here
>>> a, x
(array([-1, -2, -3], dtype=int32), array([-1., -2., -3.], dtype=float32))
```

It is important to note that once the iterator is exited, dangling references (like `x` in the example) may or may not share data with the original data `a`. If writeback semantics were active, i.e. if `x.base.flags.writebackifcopy` is `True`, then exiting the iterator will sever the connection between `x` and `a`, writing to `x` will no longer write to `a`. If writeback semantics are not active, then `x.data` will still point at some part of `a.data`, and writing to one will affect the other.

Context management and the `close` method appeared in version 1.15.0.

class `numpy.ndindex(*shape)`

An N-dimensional iterator object to index arrays.

Given the shape of an array, an `ndindex` instance iterates over the N-dimensional index of the array. At each iteration a tuple of indices is returned, the last dimension is iterated over first.

Parameters

shape

[ints, or a single tuple of ints] The size of each dimension of the array can be passed as individual parameters or as the elements of a tuple.

See also:

ndenumerate, flatiter

Examples

```
>>> import numpy as np
```

Dimensions as individual arguments

```
>>> for index in np.ndindex(3, 2, 1):
...     print(index)
(0, 0, 0)
(0, 1, 0)
(1, 0, 0)
(1, 1, 0)
(2, 0, 0)
(2, 1, 0)
```

Same dimensions - but in a tuple (3, 2, 1)

```
>>> for index in np.ndindex((3, 2, 1)):
...     print(index)
(0, 0, 0)
(0, 1, 0)
(1, 0, 0)
(1, 1, 0)
(2, 0, 0)
(2, 1, 0)
```

`numpy.nested_iters` (*op, axes, flags=None, op_flags=None, op_dtypes=None, order='K', casting='safe', buffersize=0*)

Create nditers for use in nested loops

Create a tuple of *nditer* objects which iterate in nested loops over different axes of the *op* argument. The first iterator is used in the outermost loop, the last in the innermost loop. Advancing one will change the subsequent iterators to point at its new element.

Parameters

op

[ndarray or sequence of array_like] The array(s) to iterate over.

axes

[list of list of int] Each item is used as an “op_axes” argument to an *nditer*

flags, op_flags, op_dtypes, order, casting, buffersize (optional)

See *nditer* parameters of the same name

Returns

iters

[tuple of *nditer*] An *nditer* for each item in *axes*, outermost first

See also:

nditer

Examples

Basic usage. Note how `y` is the “flattened” version of `[a[:, 0, :], a[:, 1, 0], a[:, 2, :]]` since we specified the first iter’s axes as `[1]`

```
>>> import numpy as np
>>> a = np.arange(12).reshape(2, 3, 2)
>>> i, j = np.nested_iters(a, [[1], [0, 2]], flags=["multi_index"])
>>> for x in i:
...     print(i.multi_index)
...     for y in j:
...         print(' ', j.multi_index, y)
(0,)
(0, 0) 0
(0, 1) 1
(1, 0) 6
(1, 1) 7
(1,)
(0, 0) 2
(0, 1) 3
(1, 0) 8
(1, 1) 9
(2,)
(0, 0) 4
(0, 1) 5
(1, 0) 10
(1, 1) 11
```

class `numpy.flatiter`

Flat iterator object to iterate over arrays.

A *flatiter* iterator is returned by `x.flat` for any array `x`. It allows iterating over the array as if it were a 1-D array, either in a for-loop or by calling its *next* method.

Iteration is done in row-major, C-style order (the last index varying the fastest). The iterator can also be indexed using basic slicing or advanced indexing.

Attributes

base

A reference to the array that is iterated over.

coords

An N-dimensional tuple of current coordinates.

index

Current flat index into the array.

Methods

<code>copy()</code>	Get a copy of the iterator as a 1-D array.
---------------------	--

method

`flatiter.copy()`

Get a copy of the iterator as a 1-D array.

Examples

```
>>> import numpy as np
>>> x = np.arange(6).reshape(2, 3)
>>> x
array([[0, 1, 2],
       [3, 4, 5]])
>>> fl = x.flat
>>> fl.copy()
array([0, 1, 2, 3, 4, 5])
```

See also:

`ndarray.flat`

Return a flat iterator over an array.

`ndarray.flatten`

Returns a flattened copy of an array.

Notes

A `flatiter` iterator can not be constructed directly from Python code by calling the `flatiter` constructor.

Examples

```
>>> import numpy as np
>>> x = np.arange(6).reshape(2, 3)
>>> fl = x.flat
>>> type(fl)
<class 'numpy.flatiter'>
>>> for item in fl:
...     print(item)
...
0
1
2
3
4
5
```

```
>>> fl[2:4]
array([2, 3])
```

`numpy.iterable(y)`

Check whether or not an object can be iterated over.

Parameters

y
[object] Input object.

Returns

b
[bool] Return `True` if the object has an iterator method or is a sequence and `False` otherwise.

Notes

In most cases, the results of `np.iterable(obj)` are consistent with `isinstance(obj, collections.abc.Iterable)`. One notable exception is the treatment of 0-dimensional arrays:

```
>>> from collections.abc import Iterable
>>> a = np.array(1.0) # 0-dimensional numpy array
>>> isinstance(a, Iterable)
True
>>> np.iterable(a)
False
```

Examples

```
>>> import numpy as np
>>> np.iterable([1, 2, 3])
True
>>> np.iterable(2)
False
```

1.4.11 Logic functions

Truth value testing

<code>all(a[, axis, out, keepdims, where])</code>	Test whether all array elements along a given axis evaluate to True.
<code>any(a[, axis, out, keepdims, where])</code>	Test whether any array element along a given axis evaluates to True.

`numpy.all(a, axis=None, out=None, keepdims=<no value>, *, where=<no value>)`

Test whether all array elements along a given axis evaluate to True.

Parameters

a

[array_like] Input array or object that can be converted to an array.

axis

[None or int or tuple of ints, optional] Axis or axes along which a logical AND reduction is performed. The default (`axis=None`) is to perform a logical AND over all the dimensions of the input array. *axis* may be negative, in which case it counts from the last to the first axis. If this is a tuple of ints, a reduction is performed on multiple axes, instead of a single axis or all the axes as before.

out

[ndarray, optional] Alternate output array in which to place the result. It must have the same shape as the expected output and its type is preserved (e.g., if `dtype(out)` is float, the result will consist of 0.0's and 1.0's). See `ufuncs-output-type` for more details.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.

If the default value is passed, then *keepdims* will not be passed through to the *all* method of sub-classes of *ndarray*, however any non-default value will be. If the sub-class' method does not implement *keepdims* any exceptions will be raised.

where

[array_like of bool, optional] Elements to include in checking for all *True* values. See *reduce* for details.

New in version 1.20.0.

Returns**all**

[ndarray, bool] A new boolean or array is returned unless *out* is specified, in which case a reference to *out* is returned.

See also:

ndarray.all

equivalent method

any

Test whether any element along a given axis evaluates to *True*.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to *True* because these are not equal to zero.

Changed in version 2.0: Before NumPy 2.0, *all* did not return booleans for object dtype input arrays. This behavior is still available via `np.logical_and.reduce`.

Examples

```
>>> import numpy as np
>>> np.all([[True, False], [True, True]])
False
```

```
>>> np.all([[True, False], [True, True]], axis=0)
array([ True, False])
```

```
>>> np.all([-1, 4, 5])
True
```

```
>>> np.all([1.0, np.nan])
True
```

```
>>> np.all([[True, True], [False, True]], where=[[True], [False]])
True
```

```
>>> o=np.array(False)
>>> z=np.all([-1, 4, 5], out=o)
>>> id(z), id(o), z
(28293632, 28293632, array(True)) # may vary
```

`numpy.any` (*a*, *axis=None*, *out=None*, *keepdims=<no value>*, *, *where=<no value>*)

Test whether any array element along a given axis evaluates to True.

Returns single boolean if *axis* is None

Parameters

a

[array_like] Input array or object that can be converted to an array.

axis

[None or int or tuple of ints, optional] Axis or axes along which a logical OR reduction is performed. The default (*axis=None*) is to perform a logical OR over all the dimensions of the input array. *axis* may be negative, in which case it counts from the last to the first axis. If this is a tuple of ints, a reduction is performed on multiple axes, instead of a single axis or all the axes as before.

out

[ndarray, optional] Alternate output array in which to place the result. It must have the same shape as the expected output and its type is preserved (e.g., if it is of type float, then it will remain so, returning 1.0 for True and 0.0 for False, regardless of the type of *a*). See [ufuncs-output-type](#) for more details.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.

If the default value is passed, then *keepdims* will not be passed through to the [any](#) method of sub-classes of [ndarray](#), however any non-default value will be. If the sub-class' method does not implement *keepdims* any exceptions will be raised.

where

[array_like of bool, optional] Elements to include in checking for any *True* values. See [reduce](#) for details.

New in version 1.20.0.

Returns

any

[bool or ndarray] A new boolean or [ndarray](#) is returned unless *out* is specified, in which case a reference to *out* is returned.

See also:

[ndarray.any](#)

equivalent method

[all](#)

Test whether all elements along a given axis evaluate to True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to *True* because these are not equal to zero.

Changed in version 2.0: Before NumPy 2.0, `any` did not return booleans for object dtype input arrays. This behavior is still available via `np.logical_or.reduce`.

Examples

```
>>> import numpy as np
>>> np.any([[True, False], [True, True]])
True
```

```
>>> np.any([[True, False, True ],
...         [False, False, False]], axis=0)
array([ True, False,  True])
```

```
>>> np.any([-1, 0, 5])
True
```

```
>>> np.any([[np.nan], [np.inf]], axis=1, keepdims=True)
array([[ True],
       [ True]])
```

```
>>> np.any([[True, False], [False, False]], where=[[False], [True]])
False
```

```
>>> a = np.array([[1, 0, 0],
...               [0, 0, 1],
...               [0, 0, 0]])
>>> np.any(a, axis=0)
array([ True, False,  True])
>>> np.any(a, axis=1)
array([ True,  True, False])
```

```
>>> o=np.array(False)
>>> z=np.any([-1, 4, 5], out=o)
>>> z, o
(array(True), array(True))
>>> # Check now that z is a reference to o
>>> z is o
True
>>> id(z), id(o) # identity of z and o
(191614240, 191614240)
```

Array contents

<code>isfinite(x, /[, out, where, casting, order, ...])</code>	Test element-wise for finiteness (not infinity and not Not a Number).
<code>isinf(x, /[, out, where, casting, order, ...])</code>	Test element-wise for positive or negative infinity.
<code>isnan(x, /[, out, where, casting, order, ...])</code>	Test element-wise for NaN and return result as a boolean array.
<code>isnat(x, /[, out, where, casting, order, ...])</code>	Test element-wise for NaT (not a time) and return result as a boolean array.
<code>isneginf(x[, out])</code>	Test element-wise for negative infinity, return result as bool array.
<code>isposinf(x[, out])</code>	Test element-wise for positive infinity, return result as bool array.

`numpy.isfinite(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'isfinite'>`

Test element-wise for finiteness (not infinity and not Not a Number).

The result is returned as a boolean array.

Parameters

x

[array_like] Input values.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

y

[ndarray, bool] True where *x* is not positive infinity, negative infinity, or NaN; false otherwise. This is a scalar if *x* is a scalar.

See also:

isinf, isneginf, isposinf, isnan

Notes

Not a Number, positive infinity and negative infinity are considered to be non-finite.

NumPy uses the IEEE Standard for Binary Floating-Point for Arithmetic (IEEE 754). This means that Not a Number is not equivalent to infinity. Also that positive infinity is not equivalent to negative infinity. But infinity is equivalent to positive infinity. Errors result if the second argument is also supplied when *x* is a scalar input, or if first and second arguments have different shapes.

Examples

```
>>> import numpy as np
>>> np.isfinite(1)
True
>>> np.isfinite(0)
True
>>> np.isfinite(np.nan)
False
>>> np.isfinite(np.inf)
False
>>> np.isfinite(-np.inf)
False
>>> np.isfinite([np.log(-1.), 1., np.log(0)])
array([False,  True, False])
```

```
>>> x = np.array([-np.inf, 0., np.inf])
>>> y = np.array([2, 2, 2])
>>> np.isfinite(x, y)
array([0, 1, 0])
>>> y
array([0, 1, 0])
```

`numpy.isinf(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'isinf'>`

Test element-wise for positive or negative infinity.

Returns a boolean array of the same shape as *x*, True where *x* == +/-inf, otherwise False.

Parameters

x

[array_like] Input values

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

y
 [bool (scalar) or boolean ndarray] True where x is positive or negative infinity, false otherwise.
 This is a scalar if x is a scalar.

See also:

isneginf, isposinf, isnan, isfinite

Notes

NumPy uses the IEEE Standard for Binary Floating-Point for Arithmetic (IEEE 754).

Errors result if the second argument is supplied when the first argument is a scalar, or if the first and second arguments have different shapes.

Examples

```
>>> import numpy as np
>>> np.isinf(np.inf)
True
>>> np.isinf(np.nan)
False
>>> np.isinf(-np.inf)
True
>>> np.isinf([np.inf, -np.inf, 1.0, np.nan])
array([ True,  True, False, False])
```

```
>>> x = np.array([-np.inf, 0., np.inf])
>>> y = np.array([2, 2, 2])
>>> np.isinf(x, y)
array([1, 0, 1])
>>> y
array([1, 0, 1])
```

`numpy.isnan(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'isnan'>`

Test element-wise for NaN and return result as a boolean array.

Parameters

x
 [array_like] Input array.

out
 [ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where
 [array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray or bool] True where x is NaN, false otherwise. This is a scalar if x is a scalar.

See also:

[isinf](#), [isneginf](#), [isposinf](#), [isfinite](#), [isnat](#)

Notes

NumPy uses the IEEE Standard for Binary Floating-Point for Arithmetic (IEEE 754). This means that Not a Number is not equivalent to infinity.

Examples

```
>>> import numpy as np
>>> np.isnan(np.nan)
True
>>> np.isnan(np.inf)
False
>>> np.isnan([np.log(-1.), 1., np.log(0)])
array([ True, False, False])
```

`numpy.isnan(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])` = `<ufunc 'isnan'>`

Test element-wise for NaT (not a time) and return result as a boolean array.

Parameters

x

[array_like] Input array with datetime or timedelta data type.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out*=None, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray or bool] True where x is NaT, false otherwise. This is a scalar if x is a scalar.

See also:

isnan, isinf, isneginf, isposinf, isfinite

Examples

```
>>> import numpy as np
>>> np.isnat(np.datetime64("NaT", "D"))
True
>>> np.isnat(np.datetime64("2016-01-01"))
False
>>> np.isnat(np.array(["NaT", "2016-01-01"], dtype="datetime64[ns]"))
array([ True, False])
```

`numpy.isneginf(x, out=None)`

Test element-wise for negative infinity, return result as bool array.

Parameters

x

[array_like] The input array.

out

[array_like, optional] A location into which the result is stored. If provided, it must have a shape that the input broadcasts to. If not provided or None, a freshly-allocated boolean array is returned.

Returns

out

[ndarray] A boolean array with the same dimensions as the input. If second argument is not supplied then a numpy boolean array is returned with values True where the corresponding element of the input is negative infinity and values False where the element of the input is not negative infinity.

If a second argument is supplied the result is stored there. If the type of that array is a numeric type the result is represented as zeros and ones, if the type is boolean then as False and True. The return value *out* is then a reference to that array.

See also:

isinf, isposinf, isnan, isfinite

Notes

NumPy uses the IEEE Standard for Binary Floating-Point for Arithmetic (IEEE 754).

Errors result if the second argument is also supplied when *x* is a scalar input, if first and second arguments have different shapes, or if the first argument has complex values.

Examples

```
>>> import numpy as np
>>> np.isneginf(-np.inf)
True
>>> np.isneginf(np.inf)
False
>>> np.isneginf([-np.inf, 0., np.inf])
array([ True, False, False])
```

```
>>> x = np.array([-np.inf, 0., np.inf])
>>> y = np.array([2, 2, 2])
>>> np.isneginf(x, y)
array([1, 0, 0])
>>> y
array([1, 0, 0])
```

`numpy.isposinf(x, out=None)`

Test element-wise for positive infinity, return result as bool array.

Parameters

x

[array_like] The input array.

out

[array_like, optional] A location into which the result is stored. If provided, it must have a shape that the input broadcasts to. If not provided or None, a freshly-allocated boolean array is returned.

Returns

out

[ndarray] A boolean array with the same dimensions as the input. If second argument is not supplied then a boolean array is returned with values True where the corresponding element of the input is positive infinity and values False where the element of the input is not positive infinity.

If a second argument is supplied the result is stored there. If the type of that array is a numeric type the result is represented as zeros and ones, if the type is boolean then as False and True. The return value *out* is then a reference to that array.

See also:

[*isinf*](#), [*isneginf*](#), [*isfinite*](#), [*isnan*](#)

Notes

NumPy uses the IEEE Standard for Binary Floating-Point for Arithmetic (IEEE 754).

Errors result if the second argument is also supplied when *x* is a scalar input, if first and second arguments have different shapes, or if the first argument has complex values

Examples

```
>>> import numpy as np
>>> np.isposinf(np.inf)
True
>>> np.isposinf(-np.inf)
False
>>> np.isposinf([-np.inf, 0., np.inf])
array([False, False,  True])

>>> x = np.array([-np.inf, 0., np.inf])
>>> y = np.array([2, 2, 2])
>>> np.isposinf(x, y)
array([0, 0, 1])
>>> y
array([0, 0, 1])
```

Array type testing

<code>iscomplex(x)</code>	Returns a bool array, where True if input element is complex.
<code>iscomplexobj(x)</code>	Check for a complex type or an array of complex numbers.
<code>isfortran(a)</code>	Check if the array is Fortran contiguous but <i>not</i> C contiguous.
<code>isreal(x)</code>	Returns a bool array, where True if input element is real.
<code>isrealobj(x)</code>	Return True if x is a not complex type or an array of complex numbers.
<code>isscalar(element)</code>	Returns True if the type of <i>element</i> is a scalar type.

`numpy.iscomplex(x)`

Returns a bool array, where True if input element is complex.

What is tested is whether the input has a non-zero imaginary part, not if the input type is complex.

Parameters

x
[array_like] Input array.

Returns

out
[ndarray of bools] Output array.

See also:

`isreal`
`iscomplexobj`

Return True if x is a complex type or an array of complex numbers.

Examples

```
>>> import numpy as np
>>> np.iscomplex([1+1j, 1+0j, 4.5, 3, 2, 2j])
array([ True, False, False, False, False,  True])
```

`numpy.iscomplexobj(x)`

Check for a complex type or an array of complex numbers.

The type of the input is checked, not the value. Even if the input has an imaginary part equal to zero, *iscomplexobj* evaluates to True.

Parameters

x

[any] The input can be of any type and shape.

Returns

iscomplexobj

[bool] The return value, True if *x* is of a complex type or has at least one complex element.

See also:

isrealobj, *iscomplex*

Examples

```
>>> import numpy as np
>>> np.iscomplexobj(1)
False
>>> np.iscomplexobj(1+0j)
True
>>> np.iscomplexobj([3, 1+0j, True])
True
```

`numpy.isfortran(a)`

Check if the array is Fortran contiguous but *not* C contiguous.

This function is obsolete. If you only want to check if an array is Fortran contiguous use `a.flags.f_contiguous` instead.

Parameters

a

[ndarray] Input array.

Returns

isfortran

[bool] Returns True if the array is Fortran contiguous but *not* C contiguous.

Examples

`np.array` allows to specify whether the array is written in C-contiguous order (last index varies the fastest), or FORTRAN-contiguous order in memory (first index varies the fastest).

```
>>> import numpy as np
>>> a = np.array([[1, 2, 3], [4, 5, 6]], order='C')
>>> a
array([[1, 2, 3],
       [4, 5, 6]])
>>> np.isfortran(a)
False
```

```
>>> b = np.array([[1, 2, 3], [4, 5, 6]], order='F')
>>> b
array([[1, 2, 3],
       [4, 5, 6]])
>>> np.isfortran(b)
True
```

The transpose of a C-ordered array is a FORTRAN-ordered array.

```
>>> a = np.array([[1, 2, 3], [4, 5, 6]], order='C')
>>> a
array([[1, 2, 3],
       [4, 5, 6]])
>>> np.isfortran(a)
False
>>> b = a.T
>>> b
array([[1, 4],
       [2, 5],
       [3, 6]])
>>> np.isfortran(b)
True
```

C-ordered arrays evaluate as `False` even if they are also FORTRAN-ordered.

```
>>> np.isfortran(np.array([1, 2], order='F'))
False
```

`numpy.isreal(x)`

Returns a bool array, where `True` if input element is real.

If element has complex type with zero imaginary part, the return value for that element is `True`.

Parameters

x
[array_like] Input array.

Returns

out
[ndarray, bool] Boolean array of same shape as *x*.

See also:

iscomplex

isrealobj

Return True if *x* is not a complex type.

Notes

isreal may behave unexpectedly for string or object arrays (see examples)

Examples

```
>>> import numpy as np
>>> a = np.array([1+1j, 1+0j, 4.5, 3, 2, 2j], dtype=np.complex128)
>>> np.isreal(a)
array([False,  True,  True,  True,  True, False])
```

The function does not work on string arrays.

```
>>> a = np.array([2j, "a"], dtype=np.str_)
>>> np.isreal(a) # returns the result of `"" == 0` currently.
array([False, False])
```

Returns True for all elements that either have no `.imag` attribute or for which that attribute is zero:

```
>>> a = np.array([1, "2", 3+4j], dtype=np.object_)
>>> np.isreal(a)
array([ True,  True, False])
```

`numpy.isrealobj` (*x*)

Return True if *x* is a not complex type or an array of complex numbers.

The type of the input is checked, not the value. So even if the input has an imaginary part equal to zero, *isrealobj* evaluates to False if the data type is complex.

Parameters

x
[any] The input can be of any type and shape.

Returns

y
[bool] The return value, False if *x* is of a complex type.

See also:

iscomplexobj, *isreal*

Notes

The function is only meant for arrays with numerical values but it accepts all other objects. Since it assumes array input, the return value of other objects may be True.

```
>>> np.isrealobj('A string')
True
>>> np.isrealobj(False)
True
>>> np.isrealobj(None)
True
```

Examples

```
>>> import numpy as np
>>> np.isrealobj(1)
True
>>> np.isrealobj(1+0j)
False
>>> np.isrealobj([3, 1+0j, True])
False
```

`numpy.iscscalar` (*element*)

Returns True if the type of *element* is a scalar type.

Parameters

element

[any] Input argument, can be of any type and shape.

Returns

val

[bool] True if *element* is a scalar type, False if it is not.

See also:

ndim

Get the number of dimensions of an array

Notes

If you need a stricter way to identify a *numerical* scalar, use `isinstance(x, numbers.Number)`, as that returns False for most non-numerical elements such as strings.

In most cases `np.ndim(x) == 0` should be used instead of this function, as that will also return true for 0d arrays. This is how numpy overloads functions in the style of the `dx` arguments to *gradient* and the `bins` argument to *histogram*. Some key differences:

x	isscalar(x)	np.ndim(x) == 0
PEP 3141 numeric objects (including builtins)	True	True
builtin string and buffer objects	True	True
other builtin objects, like <code>pathlib.Path</code> , <i>Exception</i> , the result of <code>re.compile</code>	False	True
third-party objects like <code>matplotlib.figure.Figure</code>	False	True
zero-dimensional numpy arrays	False	True
other numpy arrays	False	False
<i>list</i> , <i>tuple</i> , and other sequence objects	False	False

Examples

```
>>> import numpy as np
```

```
>>> np.isscalar(3.1)
True
```

```
>>> np.isscalar(np.array(3.1))
False
```

```
>>> np.isscalar([3.1])
False
```

```
>>> np.isscalar(False)
True
```

```
>>> np.isscalar('numpy')
True
```

NumPy supports PEP 3141 numbers:

```
>>> from fractions import Fraction
>>> np.isscalar(Fraction(5, 17))
True
>>> from numbers import Number
>>> np.isscalar(Number())
True
```

Logical operations

<code>logical_and(x1, x2, /[, out, where, ...])</code>	Compute the truth value of x1 AND x2 element-wise.
<code>logical_or(x1, x2, /[, out, where, casting, ...])</code>	Compute the truth value of x1 OR x2 element-wise.
<code>logical_not(x, /[, out, where, casting, ...])</code>	Compute the truth value of NOT x element-wise.
<code>logical_xor(x1, x2, /[, out, where, ...])</code>	Compute the truth value of x1 XOR x2, element-wise.

```
numpy.logical_and(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None,
                  subok=True[, signature]) = <ufunc 'logical_and'>
```

Compute the truth value of $x1$ AND $x2$ element-wise.

Parameters

$x1, x2$

[array_like] Input arrays. If $x1.shape \neq x2.shape$, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

**kwargs

For other keyword-only arguments, see the *ufunc docs*.

Returns

y

[ndarray or bool] Boolean result of the logical AND operation applied to the elements of $x1$ and $x2$; the shape is determined by broadcasting. This is a scalar if both $x1$ and $x2$ are scalars.

See also:

logical_or, *logical_not*, *logical_xor*
bitwise_and

Examples

```
>>> import numpy as np
>>> np.logical_and(True, False)
False
>>> np.logical_and([True, False], [False, False])
array([False, False])
```

```
>>> x = np.arange(5)
>>> np.logical_and(x>1, x<4)
array([False, False,  True,  True, False])
```

The `&` operator can be used as a shorthand for `np.logical_and` on boolean ndarrays.

```
>>> a = np.array([True, False])
>>> b = np.array([False, False])
>>> a & b
array([False, False])
```

```
numpy.logical_or(x1,x2,/,out=None,*,where=True,casting='same_kind',order='K',dtype=None,
                 subok=True[,signature]) = <ufunc 'logical_or'>
```

Compute the truth value of $x1$ OR $x2$ element-wise.

Parameters**x1, x2**

[array_like] Logical OR is applied to the elements of *x1* and *x2*. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**y**

[ndarray or bool] Boolean result of the logical OR operation applied to the elements of *x1* and *x2*; the shape is determined by broadcasting. This is a scalar if both *x1* and *x2* are scalars.

See also:

[logical_and](#), [logical_not](#), [logical_xor](#)
[bitwise_or](#)

Examples

```
>>> import numpy as np
>>> np.logical_or(True, False)
True
>>> np.logical_or([True, False], [False, False])
array([ True, False])
```

```
>>> x = np.arange(5)
>>> np.logical_or(x < 1, x > 3)
array([ True, False, False, False,  True])
```

The `|` operator can be used as a shorthand for `np.logical_or` on boolean ndarrays.

```
>>> a = np.array([True, False])
>>> b = np.array([False, False])
>>> a | b
array([ True, False])
```

`numpy.logical_not(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'logical_not'>`

Compute the truth value of NOT *x* element-wise.

Parameters

x
[array_like] Logical NOT is applied to the elements of *x*.

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where
[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**
For other keyword-only arguments, see the [ufunc docs](#).

Returns

y
[bool or ndarray of bool] Boolean result with the same shape as *x* of the NOT operation on elements of *x*. This is a scalar if *x* is a scalar.

See also:

[logical_and](#), [logical_or](#), [logical_xor](#)

Examples

```
>>> import numpy as np
>>> np.logical_not(3)
False
>>> np.logical_not([True, False, 0, 1])
array([False,  True,  True, False])
```

```
>>> x = np.arange(5)
>>> np.logical_not(x<3)
array([False, False, False,  True,  True])
```

`numpy.logical_xor(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'logical_xor'>`

Compute the truth value of *x1* XOR *x2*, element-wise.

Parameters

x1, x2
[array_like] Logical XOR is applied to the elements of *x1* and *x2*. If *x1.shape* != *x2.shape*, they must be broadcastable to a common shape (which becomes the shape of the output).

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**y**

[bool or ndarray of bool] Boolean result of the logical XOR operation applied to the elements of *x1* and *x2*; the shape is determined by broadcasting. This is a scalar if both *x1* and *x2* are scalars.

See also:

[logical_and](#), [logical_or](#), [logical_not](#), [bitwise_xor](#)

Examples

```
>>> import numpy as np
>>> np.logical_xor(True, False)
True
>>> np.logical_xor([True, True, False, False], [True, False, True, False])
array([False,  True,  True, False])
```

```
>>> x = np.arange(5)
>>> np.logical_xor(x < 1, x > 3)
array([ True, False, False, False,  True])
```

Simple example showing support of broadcasting

```
>>> np.logical_xor(0, np.eye(2))
array([[ True, False],
       [False,  True]])
```

Comparison

<code>allclose(a, b[, rtol, atol, equal_nan])</code>	Returns True if two arrays are element-wise equal within a tolerance.
<code>isclose(a, b[, rtol, atol, equal_nan])</code>	Returns a boolean array where two arrays are element-wise equal within a tolerance.
<code>array_equal(a1, a2[, equal_nan])</code>	True if two arrays have the same shape and elements, False otherwise.
<code>array_equiv(a1, a2)</code>	Returns True if input arrays are shape consistent and all elements equal.

`numpy.allclose(a, b, rtol=1e-05, atol=1e-08, equal_nan=False)`

Returns True if two arrays are element-wise equal within a tolerance.

The tolerance values are positive, typically very small numbers. The relative difference ($rtol * abs(b)$) and the absolute difference $atol$ are added together to compare against the absolute difference between a and b .

Warning: The default $atol$ is not appropriate for comparing numbers with magnitudes much smaller than one (see Notes).

NaNs are treated as equal if they are in the same place and if `equal_nan=True`. Infs are treated as equal if they are in the same place and of the same sign in both arrays.

Parameters

a, b

[array_like] Input arrays to compare.

rtol

[array_like] The relative tolerance parameter (see Notes).

atol

[array_like] The absolute tolerance parameter (see Notes).

equal_nan

[bool] Whether to compare NaN's as equal. If True, NaN's in a will be considered equal to NaN's in b in the output array.

Returns

allclose

[bool] Returns True if the two arrays are equal within the given tolerance; False otherwise.

See also:

[*isclose*](#), [*all*](#), [*any*](#), [*equal*](#)

Notes

If the following equation is element-wise True, then `allclose` returns True.:

$$\text{absolute}(a - b) \leq (\text{atol} + \text{rtol} * \text{absolute}(b))$$

The above equation is not symmetric in a and b , so that `allclose(a, b)` might be different from `allclose(b, a)` in some rare cases.

The default value of $atol$ is not appropriate when the reference value b has magnitude smaller than one. For example, it is unlikely that $a = 1e-9$ and $b = 2e-9$ should be considered “close”, yet `allclose(1e-9, 2e-9)` is True with default settings. Be sure to select $atol$ for the use case at hand, especially for defining the threshold below which a non-zero value in a will be considered “close” to a very small or zero value in b .

The comparison of a and b uses standard broadcasting, which means that a and b need not have the same shape in order for `allclose(a, b)` to evaluate to True. The same is true for [*equal*](#) but not [*array_equal*](#).

[*allclose*](#) is not defined for non-numeric data types. [*bool*](#) is considered a numeric data-type for this purpose.

Examples

```
>>> import numpy as np
>>> np.allclose([1e10, 1e-7], [1.00001e10, 1e-8])
False
```

```
>>> np.allclose([1e10, 1e-8], [1.00001e10, 1e-9])
True
```

```
>>> np.allclose([1e10, 1e-8], [1.0001e10, 1e-9])
False
```

```
>>> np.allclose([1.0, np.nan], [1.0, np.nan])
False
```

```
>>> np.allclose([1.0, np.nan], [1.0, np.nan], equal_nan=True)
True
```

`numpy.isclose` (*a*, *b*, *rtol*=1e-05, *atol*=1e-08, *equal_nan*=False)

Returns a boolean array where two arrays are element-wise equal within a tolerance.

The tolerance values are positive, typically very small numbers. The relative difference (*rtol* * abs(*b*)) and the absolute difference *atol* are added together to compare against the absolute difference between *a* and *b*.

Warning: The default *atol* is not appropriate for comparing numbers with magnitudes much smaller than one (see Notes).

Parameters

a, b

[array_like] Input arrays to compare.

rtol

[array_like] The relative tolerance parameter (see Notes).

atol

[array_like] The absolute tolerance parameter (see Notes).

equal_nan

[bool] Whether to compare NaN's as equal. If True, NaN's in *a* will be considered equal to NaN's in *b* in the output array.

Returns

y

[array_like] Returns a boolean array of where *a* and *b* are equal within the given tolerance. If both *a* and *b* are scalars, returns a single boolean value.

See also:

[`allclose`](#)

[`math.isclose`](#)

Notes

For finite values, `isclose` uses the following equation to test whether two floating point values are equivalent.:

```
absolute(a - b) <= (atol + rtol * absolute(b))
```

Unlike the built-in `math.isclose`, the above equation is not symmetric in a and b – it assumes b is the reference value – so that `isclose(a, b)` might be different from `isclose(b, a)`.

The default value of `atol` is not appropriate when the reference value b has magnitude smaller than one. For example, it is unlikely that $a = 1e-9$ and $b = 2e-9$ should be considered “close”, yet `isclose(1e-9, 2e-9)` is `True` with default settings. Be sure to select `atol` for the use case at hand, especially for defining the threshold below which a non-zero value in a will be considered “close” to a very small or zero value in b .

`isclose` is not defined for non-numeric data types. `bool` is considered a numeric data-type for this purpose.

Examples

```
>>> import numpy as np
>>> np.isclose([1e10, 1e-7], [1.00001e10, 1e-8])
array([ True, False])
```

```
>>> np.isclose([1e10, 1e-8], [1.00001e10, 1e-9])
array([ True, True])
```

```
>>> np.isclose([1e10, 1e-8], [1.0001e10, 1e-9])
array([False,  True])
```

```
>>> np.isclose([1.0, np.nan], [1.0, np.nan])
array([ True, False])
```

```
>>> np.isclose([1.0, np.nan], [1.0, np.nan], equal_nan=True)
array([ True, True])
```

```
>>> np.isclose([1e-8, 1e-7], [0.0, 0.0])
array([ True, False])
```

```
>>> np.isclose([1e-100, 1e-7], [0.0, 0.0], atol=0.0)
array([False, False])
```

```
>>> np.isclose([1e-10, 1e-10], [1e-20, 0.0])
array([ True,  True])
```

```
>>> np.isclose([1e-10, 1e-10], [1e-20, 0.999999e-10], atol=0.0)
array([False,  True])
```

`numpy.array_equal(a1, a2, equal_nan=False)`

True if two arrays have the same shape and elements, False otherwise.

Parameters

a1, a2

[array_like] Input arrays.

equal_nan

[bool] Whether to compare NaN's as equal. If the dtype of a1 and a2 is complex, values will be considered equal if either the real or the imaginary component of a given value is nan.

Returns**b**

[bool] Returns True if the arrays are equal.

See also:**`allclose`**

Returns True if two arrays are element-wise equal within a tolerance.

`array_equiv`

Returns True if input arrays are shape consistent and all elements equal.

Examples

```
>>> import numpy as np
```

```
>>> np.array_equal([1, 2], [1, 2])
True
```

```
>>> np.array_equal(np.array([1, 2]), np.array([1, 2]))
True
```

```
>>> np.array_equal([1, 2], [1, 2, 3])
False
```

```
>>> np.array_equal([1, 2], [1, 4])
False
```

```
>>> a = np.array([1, np.nan])
>>> np.array_equal(a, a)
False
```

```
>>> np.array_equal(a, a, equal_nan=True)
True
```

When `equal_nan` is `True`, complex values with nan components are considered equal if either the real *or* the imaginary components are nan.

```
>>> a = np.array([1 + 1j])
>>> b = a.copy()
>>> a.real = np.nan
>>> b.imag = np.nan
>>> np.array_equal(a, b, equal_nan=True)
True
```

`numpy.array_equiv(a1, a2)`

Returns True if input arrays are shape consistent and all elements equal.

Shape consistent means they are either the same shape, or one input array can be broadcasted to create the same shape as the other one.

Parameters**a1, a2**

[array_like] Input arrays.

Returns**out**

[bool] True if equivalent, False otherwise.

Examples

```
>>> import numpy as np
>>> np.array_equiv([1, 2], [1, 2])
True
>>> np.array_equiv([1, 2], [1, 3])
False
```

Showing the shape equivalence:

```
>>> np.array_equiv([1, 2], [[1, 2], [1, 2]])
True
>>> np.array_equiv([1, 2], [[1, 2, 1, 2], [1, 2, 1, 2]])
False
```

```
>>> np.array_equiv([1, 2], [[1, 2], [1, 3]])
False
```

<code>greater(x1, x2, /[, out, where, casting, ...])</code>	Return the truth value of (x1 > x2) element-wise.
<code>greater_equal(x1, x2, /[, out, where, ...])</code>	Return the truth value of (x1 >= x2) element-wise.
<code>less(x1, x2, /[, out, where, casting, ...])</code>	Return the truth value of (x1 < x2) element-wise.
<code>less_equal(x1, x2, /[, out, where, casting, ...])</code>	Return the truth value of (x1 <= x2) element-wise.
<code>equal(x1, x2, /[, out, where, casting, ...])</code>	Return (x1 == x2) element-wise.
<code>not_equal(x1, x2, /[, out, where, casting, ...])</code>	Return (x1 != x2) element-wise.

`numpy.greater(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'greater'>`

Return the truth value of (x1 > x2) element-wise.

Parameters**x1, x2**[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).**out**

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Output array, element-wise comparison of *x1* and *x2*. Typically of type bool, unless `dtype=np.object_` is passed. This is a scalar if both *x1* and *x2* are scalars.

See also:

[*greater_equal*](#), [*less*](#), [*less_equal*](#), [*equal*](#), [*not_equal*](#)

Examples

```
>>> import numpy as np
>>> np.greater([4, 2], [2, 2])
array([ True, False])
```

The `>` operator can be used as a shorthand for `np.greater` on ndarrays.

```
>>> a = np.array([4, 2])
>>> b = np.array([2, 2])
>>> a > b
array([ True, False])
```

`numpy.greater_equal(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'greater_equal'>`

Return the truth value of (*x1* `>=` *x2*) element-wise.

Parameters

x1, x2

[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[bool or ndarray of bool] Output array, element-wise comparison of *x1* and *x2*. Typically of type bool, unless `dtype=np.object_` is passed. This is a scalar if both *x1* and *x2* are scalars.

See also:

greater, less, less_equal, equal, not_equal

Examples

```
>>> import numpy as np
>>> np.greater_equal([4, 2, 1], [2, 2, 2])
array([ True,  True, False])
```

The `>=` operator can be used as a shorthand for `np.greater_equal` on ndarrays.

```
>>> a = np.array([4, 2, 1])
>>> b = np.array([2, 2, 2])
>>> a >= b
array([ True,  True, False])
```

`numpy.less(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'less'>`

Return the truth value of $(x1 < x2)$ element-wise.

Parameters

x1, x2

[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

out

[ndarray or scalar] Output array, element-wise comparison of `x1` and `x2`. Typically of type `bool`, unless `dtype=np.object_` is passed. This is a scalar if both `x1` and `x2` are scalars.

See also:

greater, less_equal, greater_equal, equal, not_equal

Examples

```
>>> import numpy as np
>>> np.less([1, 2], [2, 2])
array([ True, False])
```

The `<` operator can be used as a shorthand for `np.less` on ndarrays.

```
>>> a = np.array([1, 2])
>>> b = np.array([2, 2])
>>> a < b
array([ True, False])
```

`numpy.less_equal(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'less_equal'>`

Return the truth value of $(x1 \leq x2)$ element-wise.

Parameters

x1, x2

[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Output array, element-wise comparison of *x1* and *x2*. Typically of type bool, unless `dtype=np.object_` is passed. This is a scalar if both *x1* and *x2* are scalars.

See also:

[*greater*](#), [*less*](#), [*greater_equal*](#), [*equal*](#), [*not_equal*](#)

Examples

```
>>> import numpy as np
>>> np.less_equal([4, 2, 1], [2, 2, 2])
array([False,  True,  True])
```

The `<=` operator can be used as a shorthand for `np.less_equal` on ndarrays.

```
>>> a = np.array([4, 2, 1])
>>> b = np.array([2, 2, 2])
>>> a <= b
array([False,  True,  True])
```

`numpy.equal(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'equal'>`

Return `(x1 == x2)` element-wise.

Parameters

x1, x2

[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Output array, element-wise comparison of `x1` and `x2`. Typically of type `bool`, unless `dtype=np.object_` is passed. This is a scalar if both `x1` and `x2` are scalars.

See also:

[`not\_equal`](#), [`greater\_equal`](#), [`less\_equal`](#), [`greater`](#), [`less`](#)

Examples

```
>>> import numpy as np
>>> np.equal([0, 1, 3], np.arange(3))
array([ True,  True, False])
```

What is compared are values, not types. So an int (1) and an array of length one can evaluate as True:

```
>>> np.equal(1, np.ones(1))
array([ True])
```

The `==` operator can be used as a shorthand for `np.equal` on ndarrays.

```
>>> a = np.array([2, 4, 6])
>>> b = np.array([2, 4, 2])
>>> a == b
array([ True,  True, False])
```

`numpy.not_equal(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'not_equal'>`

Return $(x1 \neq x2)$ element-wise.

Parameters

x1, x2

[array_like] Input arrays. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Output array, element-wise comparison of `x1` and `x2`. Typically of type bool, unless `dtype=np.object_` is passed. This is a scalar if both `x1` and `x2` are scalars.

See also:

[*equal*](#), [*greater*](#), [*greater_equal*](#), [*less*](#), [*less_equal*](#)

Examples

```
>>> import numpy as np
>>> np.not_equal([1., 2.], [1., 3.])
array([False,  True])
>>> np.not_equal([1, 2], [[1, 3], [1, 4]])
array([[False,  True],
       [False,  True]])
```

The `!=` operator can be used as a shorthand for `np.not_equal` on ndarrays.

```
>>> a = np.array([1., 2.])
>>> b = np.array([1., 3.])
>>> a != b
array([False,  True])
```

1.4.12 Mathematical functions

Trigonometric functions

<code>sin(x, /[, out, where, casting, order, ...])</code>	Trigonometric sine, element-wise.
<code>cos(x, /[, out, where, casting, order, ...])</code>	Cosine element-wise.
<code>tan(x, /[, out, where, casting, order, ...])</code>	Compute tangent element-wise.
<code>arcsin(x, /[, out, where, casting, order, ...])</code>	Inverse sine, element-wise.
<code>asin(x, /[, out, where, casting, order, ...])</code>	Inverse sine, element-wise.
<code>arccos(x, /[, out, where, casting, order, ...])</code>	Trigonometric inverse cosine, element-wise.
<code>acos(x, /[, out, where, casting, order, ...])</code>	Trigonometric inverse cosine, element-wise.
<code>arctan(x, /[, out, where, casting, order, ...])</code>	Trigonometric inverse tangent, element-wise.
<code>atan(x, /[, out, where, casting, order, ...])</code>	Trigonometric inverse tangent, element-wise.
<code>hypot(x1, x2, /[, out, where, casting, ...])</code>	Given the "legs" of a right triangle, return its hypotenuse.
<code>arctan2(x1, x2, /[, out, where, casting, ...])</code>	Element-wise arc tangent of $x1/x2$ choosing the quadrant correctly.
<code>atan2(x1, x2, /[, out, where, casting, ...])</code>	Element-wise arc tangent of $x1/x2$ choosing the quadrant correctly.
<code>degrees(x, /[, out, where, casting, order, ...])</code>	Convert angles from radians to degrees.
<code>radians(x, /[, out, where, casting, order, ...])</code>	Convert angles from degrees to radians.
<code>unwrap(p[, disjoint, axis, period])</code>	Unwrap by taking the complement of large deltas with respect to the period.
<code>deg2rad(x, /[, out, where, casting, order, ...])</code>	Convert angles from degrees to radians.
<code>rad2deg(x, /[, out, where, casting, order, ...])</code>	Convert angles from radians to degrees.

```
numpy.sin(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
= <ufunc 'sin'>
```

Trigonometric sine, element-wise.

Parameters

x

[array_like] Angle, in radians (2π rad equals 360 degrees).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None,

a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[array_like] The sine of each element of *x*. This is a scalar if *x* is a scalar.

See also:

[arcsin](#), [sinh](#), [cos](#)

Notes

The sine is one of the fundamental functions of trigonometry (the mathematical study of triangles). Consider a circle of radius 1 centered on the origin. A ray comes in from the $+x$ axis, makes an angle at the origin (measured counter-clockwise from that axis), and departs from the origin. The y coordinate of the outgoing ray's intersection with the unit circle is the sine of that angle. It ranges from -1 for $x = 3\pi/2$ to +1 for $\pi/2$. The function has zeroes where the angle is a multiple of π . Sines of angles between π and 2π are negative. The numerous properties of the sine and related functions are included in any standard trigonometry text.

Examples

```
>>> import numpy as np
```

Print sine of one angle:

```
>>> np.sin(np.pi/2.)
1.0
```

Print sines of an array of angles given in degrees:

```
>>> np.sin(np.array((0., 30., 45., 60., 90.)) * np.pi / 180. )
array([ 0.          ,  0.5          ,  0.70710678,  0.8660254 ,  1.          ])
```

Plot the sine function:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-np.pi, np.pi, 201)
>>> plt.plot(x, np.sin(x))
>>> plt.xlabel('Angle [rad]')
>>> plt.ylabel('sin(x)')
>>> plt.axis('tight')
>>> plt.show()
```

```
numpy.cos(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
      = <ufunc 'cos'>
```

Cosine element-wise.

Parameters

x

[array_like] Input array in radians.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] The corresponding cosine values. This is a scalar if *x* is a scalar.

Notes

If *out* is provided, the function writes the result into it, and returns a reference to *out*. (See Examples)

Examples

```
>>> import numpy as np
>>> np.cos(np.array([0, np.pi/2, np.pi]))
array([ 1.00000000e+00,  6.12303177e-17, -1.00000000e+00])
>>>
>>> # Example of providing the optional output parameter
>>> out1 = np.array([0], dtype=np.float64)
>>> out2 = np.cos([0.1], out1)
>>> out2 is out1
True
>>>
>>> # Example of ValueError due to provision of shape mis-matched `out`
>>> np.cos(np.zeros((3,3)), np.zeros((2,2)))
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operands could not be broadcast together with shapes (3,3) (2,2)
```

```
numpy.tan(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
      = <ufunc 'tan'>
```

Compute tangent element-wise.

Equivalent to `np.sin(x)/np.cos(x)` element-wise.

Parameters

x
[array_like] Input array.

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where
[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**
For other keyword-only arguments, see the [ufunc docs](#).

Returns

y
[ndarray] The corresponding tangent values. This is a scalar if *x* is a scalar.

Notes

If *out* is provided, the function writes the result into it, and returns a reference to *out*. (See Examples)

References

M. Abramowitz and I. A. Stegun, Handbook of Mathematical Functions. New York, NY: Dover, 1972.

Examples

```
>>> import numpy as np
>>> from math import pi
>>> np.tan(np.array([-pi,pi/2,pi]))
array([ 1.22460635e-16,  1.63317787e+16, -1.22460635e-16])
>>>
>>> # Example of providing the optional output parameter illustrating
>>> # that what is returned is a reference to said parameter
>>> out1 = np.array([0], dtype=np.float64)
>>> out2 = np.cos([0.1], out1)
>>> out2 is out1
True
>>>
>>> # Example of ValueError due to provision of shape mis-matched `out`
>>> np.cos(np.zeros((3,3)), np.zeros((2,2)))
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operands could not be broadcast together with shapes (3,3) (2,2)
```

`numpy.arcsin(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'arcsin'>`

Inverse sine, element-wise.

Parameters

x
[array_like] y-coordinate on the unit circle.

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where
[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**
For other keyword-only arguments, see the *ufunc docs*.

Returns

angle
[ndarray] The inverse sine of each element in *x*, in radians and in the closed interval $[-\pi/2, \pi/2]$. This is a scalar if *x* is a scalar.

See also:

`sin`, *`cos`*, *`arccos`*, *`tan`*, *`arctan`*, *`arctan2`*, *`emath.arcsin`*

Notes

`arcsin` is a multivalued function: for each x there are infinitely many numbers z such that $\sin(z) = x$. The convention is to return the angle z whose real part lies in $[-\pi/2, \pi/2]$.

For real-valued input data types, *`arcsin`* always returns real output. For each value that cannot be expressed as a real number or infinity, it yields `nan` and sets the *invalid* floating point error flag.

For complex-valued input, *`arcsin`* is a complex analytic function that has, by convention, the branch cuts $[-\infty, -1]$ and $[1, \infty]$ and is continuous from above on the former and from below on the latter.

The inverse sine is also known as *`asin`* or $\sin^{-1}$.

Abramowitz, M. and Stegun, I. A., *Handbook of Mathematical Functions*, 10th printing, New York: Dover, 1964, pp. 79ff. https://personal.math.ubc.ca/~cbm/aands/page_79.htm

Examples

```
>>> import numpy as np
>>> np.arcsin(1)      # pi/2
1.5707963267948966
>>> np.arcsin(-1)    # -pi/2
-1.5707963267948966
>>> np.arcsin(0)
0.0
```

```
numpy.asin(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
      = <ufunc 'arcsin'>
```

Inverse sine, element-wise.

Parameters

x

[array_like] y-coordinate on the unit circle.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or `None`, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is `True`, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

angle

[ndarray] The inverse sine of each element in x , in radians and in the closed interval $[-\pi/2, \pi/2]$. This is a scalar if x is a scalar.

See also:

`sin`, `cos`, `arccos`, `tan`, `arctan`, `arctan2`, `emath.arcsin`

Notes

`arcsin` is a multivalued function: for each x there are infinitely many numbers z such that $\sin(z) = x$. The convention is to return the angle z whose real part lies in $[-\pi/2, \pi/2]$.

For real-valued input data types, `arcsin` always returns real output. For each value that cannot be expressed as a real number or infinity, it yields `nan` and sets the *invalid* floating point error flag.

For complex-valued input, `arcsin` is a complex analytic function that has, by convention, the branch cuts $[-\infty, -1]$ and $[1, \infty]$ and is continuous from above on the former and from below on the latter.

The inverse sine is also known as `asin` or $\sin^{-1}$.

Abramowitz, M. and Stegun, I. A., *Handbook of Mathematical Functions*, 10th printing, New York: Dover, 1964, pp. 79ff. https://personal.math.ubc.ca/~cbm/aands/page_79.htm

Examples

```
>>> import numpy as np
>>> np.arcsin(1)      # pi/2
1.5707963267948966
>>> np.arcsin(-1)    # -pi/2
-1.5707963267948966
>>> np.arcsin(0)
0.0
```

```
numpy.arccos(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'arccos'>
```

Trigonometric inverse cosine, element-wise.

The inverse of `cos` so that, if $y = \cos(x)$, then $x = \arccos(y)$.

Parameters

x

[array_like] x -coordinate on the unit circle. For real arguments, the domain is $[-1, 1]$.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or `None`, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns**angle**

[ndarray] The angle of the ray intersecting the unit circle at the given *x*-coordinate in radians $[0, \pi]$. This is a scalar if *x* is a scalar.

See also:

cos, *arctan*, *arcsin*, *emath.arccos*

Notes

arccos is a multivalued function: for each *x* there are infinitely many numbers *z* such that $\cos(z) = x$. The convention is to return the angle *z* whose real part lies in $[0, \pi]$.

For real-valued input data types, *arccos* always returns real output. For each value that cannot be expressed as a real number or infinity, it yields *nan* and sets the *invalid* floating point error flag.

For complex-valued input, *arccos* is a complex analytic function that has branch cuts $[-\infty, -1]$ and $[1, \infty]$ and is continuous from above on the former and from below on the latter.

The inverse *cos* is also known as *acos* or $\cos^{-1}$.

References

M. Abramowitz and I.A. Stegun, “Handbook of Mathematical Functions”, 10th printing, 1964, pp. 79. https://personal.math.ubc.ca/~cbm/aands/page_79.htm

Examples

```
>>> import numpy as np
```

We expect the arccos of 1 to be 0, and of -1 to be pi:

```
>>> np.arccos([1, -1])
array([ 0.          ,  3.14159265])
```

Plot arccos:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-1, 1, num=100)
>>> plt.plot(x, np.arccos(x))
>>> plt.axis('tight')
>>> plt.show()
```

```
numpy.acos (x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
      = <ufunc 'arccos'>
```

Trigonometric inverse cosine, element-wise.

The inverse of `cos` so that, if $y = \cos(x)$, then $x = \arccos(y)$.

Parameters

x

[array_like] x -coordinate on the unit circle. For real arguments, the domain is $[-1, 1]$.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

angle

[ndarray] The angle of the ray intersecting the unit circle at the given x -coordinate in radians $[0, \pi]$. This is a scalar if x is a scalar.

See also:

[cos](#), [arctan](#), [arcsin](#), [emath.arccos](#)

Notes

`arccos` is a multivalued function: for each x there are infinitely many numbers z such that $\cos(z) = x$. The convention is to return the angle z whose real part lies in $[0, \pi]$.

For real-valued input data types, `arccos` always returns real output. For each value that cannot be expressed as a real number or infinity, it yields `nan` and sets the *invalid* floating point error flag.

For complex-valued input, `arccos` is a complex analytic function that has branch cuts $[-\infty, -1]$ and $[1, \infty]$ and is continuous from above on the former and from below on the latter.

The inverse `cos` is also known as `acos` or $\cos^{-1}$.

References

M. Abramowitz and I.A. Stegun, “Handbook of Mathematical Functions”, 10th printing, 1964, pp. 79. https://personal.math.ubc.ca/~cbm/aands/page_79.htm

Examples

```
>>> import numpy as np
```

We expect the arccos of 1 to be 0, and of -1 to be pi:

```
>>> np.arccos([1, -1])
array([ 0.          ,  3.14159265])
```

Plot arccos:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-1, 1, num=100)
>>> plt.plot(x, np.arccos(x))
>>> plt.axis('tight')
>>> plt.show()
```

```
numpy.arctan(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature
              ]) = <ufunc 'arctan'>
```

Trigonometric inverse tangent, element-wise.

The inverse of `tan`, so that if `y = tan(x)` then `x = arctan(y)`.

Parameters

x

[array_like]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Out has the same shape as *x*. Its real part is in $[-\pi/2, \pi/2]$ (`arctan(+/-inf)` returns $\pm\pi/2$). This is a scalar if *x* is a scalar.

See also:

[*arctan2*](#)

The “four quadrant” arctan of the angle formed by (*x*, *y*) and the positive *x*-axis.

[*angle*](#)

Argument of complex values.

Notes

[*arctan*](#) is a multi-valued function: for each *x* there are infinitely many numbers *z* such that $\tan(z) = x$. The convention is to return the angle *z* whose real part lies in $[-\pi/2, \pi/2]$.

For real-valued input data types, [*arctan*](#) always returns real output. For each value that cannot be expressed as a real number or infinity, it yields `nan` and sets the *invalid* floating point error flag.

For complex-valued input, [*arctan*](#) is a complex analytic function that has $[1j, \text{inf}j]$ and $[-1j, -\text{inf}j]$ as branch cuts, and is continuous from the left on the former and from the right on the latter.

The inverse tangent is also known as [*atan*](#) or $\tan^{-1}$.

References

Abramowitz, M. and Stegun, I. A., *Handbook of Mathematical Functions*, 10th printing, New York: Dover, 1964, pp. 79. https://personal.math.ubc.ca/~cbm/aands/page_79.htm

Examples

We expect the arctan of 0 to be 0, and of 1 to be $\pi/4$:

```
>>> import numpy as np
>>> np.arctan([0, 1])
array([ 0.          ,  0.78539816])
```

```
>>> np.pi/4
0.78539816339744828
```

Plot arctan:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-10, 10)
>>> plt.plot(x, np.arctan(x))
>>> plt.axis('tight')
>>> plt.show()
```

```
numpy.atan(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
      = <ufunc 'arctan'>
```

Trigonometric inverse tangent, element-wise.

The inverse of $\tan$, so that if $y = \tan(x)$ then $x = \arctan(y)$.

Parameters

x
[array_like]

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns**out**

[ndarray or scalar] Out has the same shape as *x*. Its real part is in $[-\pi/2, \pi/2]$ ($\arctan(+/-\infty)$ returns $+/-\pi/2$). This is a scalar if *x* is a scalar.

See also:*arctan2*

The “four quadrant” arctan of the angle formed by (*x*, *y*) and the positive *x*-axis.

angle

Argument of complex values.

Notes

arctan is a multi-valued function: for each *x* there are infinitely many numbers *z* such that $\tan(z) = x$. The convention is to return the angle *z* whose real part lies in $[-\pi/2, \pi/2]$.

For real-valued input data types, *arctan* always returns real output. For each value that cannot be expressed as a real number or infinity, it yields *nan* and sets the *invalid* floating point error flag.

For complex-valued input, *arctan* is a complex analytic function that has $[1j, \infty j]$ and $[-1j, -\infty j]$ as branch cuts, and is continuous from the left on the former and from the right on the latter.

The inverse tangent is also known as *atan* or $\tan^{-1}$.

References

Abramowitz, M. and Stegun, I. A., *Handbook of Mathematical Functions*, 10th printing, New York: Dover, 1964, pp. 79. https://personal.math.ubc.ca/~cbm/aands/page_79.htm

Examples

We expect the arctan of 0 to be 0, and of 1 to be $\pi/4$:

```
>>> import numpy as np
>>> np.arctan([0, 1])
array([ 0.          ,  0.78539816])
```

```
>>> np.pi/4
0.78539816339744828
```

Plot arctan:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-10, 10)
>>> plt.plot(x, np.arctan(x))
>>> plt.axis('tight')
>>> plt.show()
```

`numpy.hypot` (*x1*, *x2*, /, *out*=None, *, *where*=True, *casting*='same_kind', *order*='K', *dtype*=None, *subok*=True[, *signature*]) = <ufunc 'hypot'>

Given the “legs” of a right triangle, return its hypotenuse.

Equivalent to `sqrt(x1**2 + x2**2)`, element-wise. If *x1* or *x2* is scalar_like (i.e., unambiguously cast-able to a scalar type), it is broadcast for use with each element of the other argument. (See Examples)

Parameters

x1, x2

[array_like] Leg of the triangle(s). If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**z**

[ndarray] The hypotenuse of the triangle(s). This is a scalar if both *x1* and *x2* are scalars.

Examples

```
>>> import numpy as np
>>> np.hypot(3*np.ones((3, 3)), 4*np.ones((3, 3)))
array([[ 5.,  5.,  5.],
       [ 5.,  5.,  5.],
       [ 5.,  5.,  5.]])
```

Example showing broadcast of scalar_like argument:

```
>>> np.hypot(3*np.ones((3, 3)), [4])
array([[ 5.,  5.,  5.],
       [ 5.,  5.,  5.],
       [ 5.,  5.,  5.]])
```

`numpy.arctan2(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'arctan2'>`

Element-wise arc tangent of $x1/x2$ choosing the quadrant correctly.

The quadrant (i.e., branch) is chosen so that `arctan2(x1, x2)` is the signed angle in radians between the ray ending at the origin and passing through the point (1,0), and the ray ending at the origin and passing through the point ($x2, x1$). (Note the role reversal: the “y-coordinate” is the first function parameter, the “x-coordinate” is the second.) By IEEE convention, this function is defined for $x2 = +/-0$ and for either or both of $x1$ and $x2 = +/-inf$ (see Notes for specific values).

This function is not defined for complex-valued arguments; for the so-called argument of complex values, use [angle](#).

Parameters**x1**

[array_like, real-valued] y-coordinates.

x2

[array_like, real-valued] x-coordinates. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**angle**

[ndarray] Array of angles in radians, in the range $[-\pi, \pi]$. This is a scalar if both *x1* and *x2* are scalars.

See also:

[arctan](#), [tan](#), [angle](#)

Notes

arctan2 is identical to the [atan2](#) function of the underlying C library. The following special values are defined in the C standard: [1]

<i>x1</i>	<i>x2</i>	<i>arctan2(x1,x2)</i>
+/- 0	+0	+/- 0
+/- 0	-0	+/- pi
> 0	+/-inf	+0 / +pi
< 0	+/-inf	-0 / -pi
+/-inf	+inf	+/- (pi/4)
+/-inf	-inf	+/- (3*pi/4)

Note that +0 and -0 are distinct floating point numbers, as are +inf and -inf.

References

[1]

Examples

Consider four points in different quadrants:

```
>>> import numpy as np
>>> x = np.array([-1, +1, +1, -1])
>>> y = np.array([-1, -1, +1, +1])
>>> np.arctan2(y, x) * 180 / np.pi
array([-135.,  -45.,   45.,  135.] )
```

Note the order of the parameters. *arctan2* is defined also when *x2* = 0 and at several other special points, obtaining values in the range $[-\pi, \pi]$:

```
>>> np.arctan2([1., -1.], [0., 0.])
array([ 1.57079633, -1.57079633])
>>> np.arctan2([0., 0., np.inf], [+0., -0., np.inf])
array([0.,          , 3.14159265, 0.78539816])
```

`numpy.atan2(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'arctan2'>`

Element-wise arc tangent of $x1/x2$ choosing the quadrant correctly.

The quadrant (i.e., branch) is chosen so that `arctan2(x1, x2)` is the signed angle in radians between the ray ending at the origin and passing through the point (1,0), and the ray ending at the origin and passing through the point ($x2, x1$). (Note the role reversal: the “y-coordinate” is the first function parameter, the “x-coordinate” is the second.) By IEEE convention, this function is defined for $x2 = +/-0$ and for either or both of $x1$ and $x2 = +/-inf$ (see Notes for specific values).

This function is not defined for complex-valued arguments; for the so-called argument of complex values, use [angle](#).

Parameters

x1

[array_like, real-valued] y-coordinates.

x2

[array_like, real-valued] x-coordinates. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

angle

[ndarray] Array of angles in radians, in the range $[-\pi, \pi]$. This is a scalar if both `x1` and `x2` are scalars.

See also:

[arctan](#), [tan](#), [angle](#)

Notes

`arctan2` is identical to the `atan2` function of the underlying C library. The following special values are defined in the C standard: [1]

$x1$	$x2$	$\arctan2(x1, x2)$
± 0	$+0$	± 0
± 0	-0	$\pm \pi$
> 0	$\pm \text{inf}$	$+0 / +\pi$
< 0	$\pm \text{inf}$	$-0 / -\pi$
$\pm \text{inf}$	$+\text{inf}$	$\pm (\pi/4)$
$\pm \text{inf}$	$-\text{inf}$	$\pm (3\pi/4)$

Note that $+0$ and -0 are distinct floating point numbers, as are $+\text{inf}$ and $-\text{inf}$.

References

[1]

Examples

Consider four points in different quadrants:

```
>>> import numpy as np
>>> x = np.array([-1, +1, +1, -1])
>>> y = np.array([-1, -1, +1, +1])
>>> np.arctan2(y, x) * 180 / np.pi
array([-135.,  -45.,   45.,  135.])
```

Note the order of the parameters. `arctan2` is defined also when $x2 = 0$ and at several other special points, obtaining values in the range $[-\pi, \pi]$:

```
>>> np.arctan2([1., -1.], [0., 0.])
array([ 1.57079633, -1.57079633])
>>> np.arctan2([0., 0., np.inf], [+0., -0., np.inf])
array([0.,          , 3.14159265, 0.78539816])
```

`numpy.degrees` (`x`, `/`, `out=None`, `*`, `where=True`, `casting='same_kind'`, `order='K'`, `dtype=None`, `subok=True` [`signature`]) = `<ufunc 'degrees'>`

Convert angles from radians to degrees.

Parameters

x

[array_like] Input array in radians.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**y**

[ndarray of floats] The corresponding degree values; if *out* was supplied this is a reference to it. This is a scalar if *x* is a scalar.

See also:**[rad2deg](#)**

equivalent function

Examples

Convert a radian array to degrees

```
>>> import numpy as np
>>> rad = np.arange(12.)*np.pi/6
>>> np.degrees(rad)
array([  0.,  30.,  60.,  90., 120., 150., 180., 210., 240.,
        270., 300., 330.] )
```

```
>>> out = np.zeros((rad.shape))
>>> r = np.degrees(rad, out)
>>> np.all(r == out)
True
```

`numpy.radians` (*x*, */*, *out=None*, ***, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True* [, *signature*]) = <ufunc 'radians'>

Convert angles from degrees to radians.

Parameters**x**

[array_like] Input array in degrees.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**y**[ndarray] The corresponding radian values. This is a scalar if x is a scalar.**See also:**[*deg2rad*](#)

equivalent function

Examples

```
>>> import numpy as np
```

Convert a degree array to radians

```
>>> deg = np.arange(12.) * 30.
>>> np.radians(deg)
array([ 0.          ,  0.52359878,  1.04719755,  1.57079633,  2.0943951 ,
        2.61799388,  3.14159265,  3.66519143,  4.1887902 ,  4.71238898,
        5.23598776,  5.75958653])
```

```
>>> out = np.zeros((deg.shape))
>>> ret = np.radians(deg, out)
>>> ret is out
True
```

`numpy.unwrap`(*p*, *discont*=None, *axis*=-1, *, *period*=6.283185307179586)

Unwrap by taking the complement of large deltas with respect to the period.

This unwraps a signal *p* by changing elements which have an absolute difference from their predecessor of more than `max(discont, period/2)` to their *period*-complementary values.For the default case where *period* is 2π and *discont* is π , this unwraps a radian phase *p* such that adjacent differences are never greater than π by adding $2k\pi$ for some integer *k*.**Parameters****p**

[array_like] Input array.

discont[float, optional] Maximum discontinuity between values, default is `period/2`. Values below `period/2` are treated as if they were `period/2`. To have an effect different from the default, *discont* should be larger than `period/2`.**axis**

[int, optional] Axis along which unwrap will operate, default is the last axis.

period[float, optional] Size of the range over which the input wraps. By default, it is `2 * pi`.

New in version 1.21.0.

Returns**out**

[ndarray] Output array.

See also:

*rad2deg, deg2rad***Notes**

If the discontinuity in p is smaller than $\text{period}/2$, but larger than *discont*, no unwrapping is done because taking the complement would only make the discontinuity larger.

Examples

```
>>> import numpy as np
```

```
>>> phase = np.linspace(0, np.pi, num=5)
>>> phase[3:] += np.pi
>>> phase
array([ 0.          ,  0.78539816,  1.57079633,  5.49778714,  6.28318531]) # may vary
>>> np.unwrap(phase)
array([ 0.          ,  0.78539816,  1.57079633, -0.78539816,  0.          ]) # may vary
>>> np.unwrap([0, 1, 2, -1, 0], period=4)
array([0, 1, 2, 3, 4])
>>> np.unwrap([ 1, 2, 3, 4, 5, 6, 1, 2, 3], period=6)
array([1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> np.unwrap([2, 3, 4, 5, 2, 3, 4, 5], period=4)
array([2, 3, 4, 5, 6, 7, 8, 9])
>>> phase_deg = np.mod(np.linspace(0, 720, 19), 360) - 180
>>> np.unwrap(phase_deg, period=360)
array([-180., -140., -100.,  -60.,  -20.,   20.,   60.,  100.,  140.,
        180.,  220.,  260.,  300.,  340.,  380.,  420.,  460.,  500.,
        540.])
```

This example plots the unwrapping of the wrapped input signal w . First generate w , then apply *unwrap* to get u .

```
>>> t = np.linspace(0, 25, 801)
>>> w = np.mod(1.5 * np.sin(1.1 * t + 0.26) * (1 - t / 6 + (t / 23) ** 3), 2.0) - 1
>>> u = np.unwrap(w, period=2.0)
```

Plot w and u .

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, w, label='w (a signal wrapped to [-1, 1])')
>>> plt.plot(t, u, linewidth=2.5, alpha=0.5, label='unwrap(w, period=2)')
>>> plt.xlabel('t')
>>> plt.grid(alpha=0.6)
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.show()
```

`numpy.deg2rad` (x , /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'deg2rad'>

Convert angles from degrees to radians.

Parameters

x

[array_like] Angles in degrees.

**out**

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**y**

[ndarray] The corresponding angle in radians. This is a scalar if *x* is a scalar.

See also:**[rad2deg](#)**

Convert angles from radians to degrees.

[unwrap](#)

Remove large jumps in angle by wrapping.

Notes

`deg2rad(x)` is $x * \pi / 180$.

Examples

```
>>> import numpy as np
>>> np.deg2rad(180)
3.1415926535897931
```

```
numpy.rad2deg(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'rad2deg'>
```

Convert angles from radians to degrees.

Parameters

x

[array_like] Angle in radians.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] The corresponding angle in degrees. This is a scalar if *x* is a scalar.

See also:

[*deg2rad*](#)

Convert angles from degrees to radians.

[*unwrap*](#)

Remove large jumps in angle by wrapping.

Notes

`rad2deg(x)` is $180 * x / \pi$.

Examples

```
>>> import numpy as np
>>> np.rad2deg(np.pi/2)
90.0
```

Hyperbolic functions

<code>sinh(x, /[, out, where, casting, order, ...])</code>	Hyperbolic sine, element-wise.
<code>cosh(x, /[, out, where, casting, order, ...])</code>	Hyperbolic cosine, element-wise.
<code>tanh(x, /[, out, where, casting, order, ...])</code>	Hyperbolic tangent, element-wise.
<code>arcsinh(x, /[, out, where, casting, order, ...])</code>	Inverse hyperbolic sine, element-wise.
<code>asinh(x, /[, out, where, casting, order, ...])</code>	Inverse hyperbolic sine, element-wise.
<code>acccosh(x, /[, out, where, casting, order, ...])</code>	Inverse hyperbolic cosine, element-wise.
<code>acosh(x, /[, out, where, casting, order, ...])</code>	Inverse hyperbolic cosine, element-wise.
<code>arctanh(x, /[, out, where, casting, order, ...])</code>	Inverse hyperbolic tangent, element-wise.
<code>atanh(x, /[, out, where, casting, order, ...])</code>	Inverse hyperbolic tangent, element-wise.

```
numpy.sinh(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
= <ufunc 'sinh'>
```

Hyperbolic sine, element-wise.

Equivalent to $1/2 * (\text{np.exp}(x) - \text{np.exp}(-x))$ or $-1j * \text{np.sin}(1j*x)$.

Parameters

x

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] The corresponding hyperbolic sine values. This is a scalar if *x* is a scalar.

Notes

If *out* is provided, the function writes the result into it, and returns a reference to *out*. (See Examples)

Examples

```
>>> import numpy as np
>>> np.sinh(0)
0.0
>>> np.sinh(np.pi*1j/2)
1j
>>> np.sinh(np.pi*1j) # (exact value is 0)
1.2246063538223773e-016j
>>> # Discrepancy due to vagaries of floating point arithmetic.
```

```
>>> # Example of providing the optional output parameter
>>> out1 = np.array([0], dtype=np.float64)
>>> out2 = np.sinh([0.1], out1)
>>> out2 is out1
True
```

```
>>> # Example of ValueError due to provision of shape mis-matched `out`
>>> np.sinh(np.zeros((3,3)), np.zeros((2,2)))
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operands could not be broadcast together with shapes (3,3) (2,2)
```

```
numpy.cosh(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
= <ufunc 'cosh'>
```

Hyperbolic cosine, element-wise.

Equivalent to $1/2 * (\text{np.exp}(x) + \text{np.exp}(-x))$ and $\text{np.cos}(1j*x)$.

Parameters

x

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns**out**[ndarray or scalar] Output array of same shape as x . This is a scalar if x is a scalar.**Examples**

```
>>> import numpy as np
>>> np.cosh(0)
1.0
```

The hyperbolic cosine describes the shape of a hanging cable:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-4, 4, 1000)
>>> plt.plot(x, np.cosh(x))
>>> plt.show()
```

```
numpy.tanh(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
= <ufunc 'tanh'>
```

Hyperbolic tangent, element-wise.

Equivalent to $\text{np.sinh}(x) / \text{np.cosh}(x)$ or $-1j * \text{np.tan}(1j*x)$.**Parameters****x**

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the con-

dition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

y

[ndarray] The corresponding hyperbolic tangent values. This is a scalar if *x* is a scalar.

Notes

If *out* is provided, the function writes the result into it, and returns a reference to *out*. (See Examples)

References

[1], [2]

Examples

```
>>> import numpy as np
>>> np.tanh((0, np.pi*1j, np.pi*1j/2))
array([ 0. +0.00000000e+00j,  0. -1.22460635e-16j,  0. +1.63317787e+16j])
```

```
>>> # Example of providing the optional output parameter illustrating
>>> # that what is returned is a reference to said parameter
>>> out1 = np.array([0], dtype=np.float64)
>>> out2 = np.tanh([0.1], out1)
>>> out2 is out1
True
```

```
>>> # Example of ValueError due to provision of shape mis-matched `out`
>>> np.tanh(np.zeros((3,3)), np.zeros((2,2)))
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operands could not be broadcast together with shapes (3,3) (2,2)
```

`numpy.arcsinh(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'arcsinh'>`

Inverse hyperbolic sine, element-wise.

Parameters

x

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**out**

[ndarray or scalar] Array of the same shape as *x*. This is a scalar if *x* is a scalar.

Notes

[arcsinh](#) is a multivalued function: for each *x* there are infinitely many numbers *z* such that $\sinh(z) = x$. The convention is to return the *z* whose imaginary part lies in $[-\pi/2, \pi/2]$.

For real-valued input data types, [arcsinh](#) always returns real output. For each value that cannot be expressed as a real number or infinity, it returns `nan` and sets the *invalid* floating point error flag.

For complex-valued input, [arcsinh](#) is a complex analytical function that has branch cuts $[1j, \infty]$ and $[-1j, -\infty]$ and is continuous from the right on the former and from the left on the latter.

The inverse hyperbolic sine is also known as [asinh](#) or $\sinh^{-1}$.

References

[1], [2]

Examples

```
>>> import numpy as np
>>> np.arcsinh(np.array([np.e, 10.0]))
array([ 1.72538256,  2.99822295])
```

```
numpy.asinh(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'arcsinh'>
```

Inverse hyperbolic sine, element-wise.

Parameters**x**

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain

its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Array of the same shape as *x*. This is a scalar if *x* is a scalar.

Notes

[arcsinh](#) is a multivalued function: for each *x* there are infinitely many numbers *z* such that $\sinh(z) = x$. The convention is to return the *z* whose imaginary part lies in $[-\pi/2, \pi/2]$.

For real-valued input data types, [arcsinh](#) always returns real output. For each value that cannot be expressed as a real number or infinity, it returns `nan` and sets the *invalid* floating point error flag.

For complex-valued input, [arcsinh](#) is a complex analytical function that has branch cuts $[1j, \infty]$ and $[-1j, -\infty]$ and is continuous from the right on the former and from the left on the latter.

The inverse hyperbolic sine is also known as [asinh](#) or $\sinh^{-1}$.

>>> np.arcsinh(np.array([np.e, 10.0]))
array([ 1.72538256,  2.99822295])
```

```
numpy.arccosh(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature ]) = <ufunc 'arccosh'>
```

Inverse hyperbolic cosine, element-wise.

Parameters

x

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or `None`, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is `True`, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

`arccosh`

[ndarray] Array of the same shape as *x*. This is a scalar if *x* is a scalar.

See also:

[*cosh*](#), [*arcsinh*](#), [*sinh*](#), [*arctanh*](#), [*tanh*](#)

Notes

[*arccosh*](#) is a multivalued function: for each *x* there are infinitely many numbers *z* such that $\cosh(z) = x$. The convention is to return the *z* whose imaginary part lies in $[-\pi, \pi]$ and the real part in $[0, \infty]$.

For real-valued input data types, [*arccosh*](#) always returns real output. For each value that cannot be expressed as a real number or infinity, it yields `nan` and sets the *invalid* floating point error flag.

For complex-valued input, [*arccosh*](#) is a complex analytical function that has a branch cut $[-\infty, 1]$ and is continuous from above on it.

References

[1], [2]

Examples

```
>>> import numpy as np
>>> np.arccosh([np.e, 10.0])
array([ 1.65745445,  2.99322285])
>>> np.arccosh(1)
0.0
```

```
numpy.acosh(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature
]) = <ufunc 'arccosh'>
```

Inverse hyperbolic cosine, element-wise.

Parameters

x

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [*ufunc docs*](#).

Returns**arccosh**

[ndarray] Array of the same shape as x . This is a scalar if x is a scalar.

See also:

[*cosh*](#), [*arcsinh*](#), [*sinh*](#), [*arctanh*](#), [*tanh*](#)

Notes

[*arccosh*](#) is a multivalued function: for each x there are infinitely many numbers z such that $\cosh(z) = x$. The convention is to return the z whose imaginary part lies in $[-\pi, \pi]$ and the real part in $[0, \infty]$.

For real-valued input data types, [*arccosh*](#) always returns real output. For each value that cannot be expressed as a real number or infinity, it yields `nan` and sets the *invalid* floating point error flag.

For complex-valued input, [*arccosh*](#) is a complex analytical function that has a branch cut $[-\infty, 1]$ and is continuous from above on it.

>>> np.arccosh(1)
0.0
```

```
numpy.arctanh(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'arctanh'>
```

Inverse hyperbolic tangent, element-wise.

Parameters**x**

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [*ufunc docs*](#).

Returns

out

[ndarray or scalar] Array of the same shape as *x*. This is a scalar if *x* is a scalar.

See also:

[`emath.arctanh`](#)

Notes

[`arctanh`](#) is a multivalued function: for each *x* there are infinitely many numbers *z* such that $\tanh(z) = x$. The convention is to return the *z* whose imaginary part lies in $[-\pi/2, \pi/2]$.

For real-valued input data types, [`arctanh`](#) always returns real output. For each value that cannot be expressed as a real number or infinity, it yields `nan` and sets the *invalid* floating point error flag.

For complex-valued input, [`arctanh`](#) is a complex analytical function that has branch cuts $[-1, -inf]$ and $[1, inf]$ and is continuous from above on the former and from below on the latter.

The inverse hyperbolic tangent is also known as [`atanh`](#) or $\tanh^{-1}$.

```

```
numpy.atanh(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'arctanh'>
```

Inverse hyperbolic tangent, element-wise.

Parameters

x

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or `None`, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is `True`, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [*ufunc docs*](#).

Returns

out[ndarray or scalar] Array of the same shape as *x*. This is a scalar if *x* is a scalar.**See also:**[`emath.arctanh`](#)

Notes

[`arctanh`](#) is a multivalued function: for each *x* there are infinitely many numbers *z* such that $\tanh(z) = x$. The convention is to return the *z* whose imaginary part lies in $[-\pi/2, \pi/2]$.

For real-valued input data types, [`arctanh`](#) always returns real output. For each value that cannot be expressed as a real number or infinity, it yields `nan` and sets the *invalid* floating point error flag.

For complex-valued input, [`arctanh`](#) is a complex analytical function that has branch cuts $[-1, -\text{inf}]$ and $[1, \text{inf}]$ and is continuous from above on the former and from below on the latter.

The inverse hyperbolic tangent is also known as [`atanh`](#) or $\tanh^{-1}$.

References

[1], [2]

Examples

```
>>> import numpy as np
>>> np.arctanh([0, -0.5])
array([ 0.          , -0.54930614])
```

Rounding

<code>round(a[, decimals, out])</code>	Evenly round to the given number of decimals.
<code>around(a[, decimals, out])</code>	Round an array to the given number of decimals.
<code>rint(x, /[, out, where, casting, order, ...])</code>	Round elements of the array to the nearest integer.
<code>fix(x[, out])</code>	Round to nearest integer towards zero.
<code>floor(x, /[, out, where, casting, order, ...])</code>	Return the floor of the input, element-wise.
<code>ceil(x, /[, out, where, casting, order, ...])</code>	Return the ceiling of the input, element-wise.
<code>trunc(x, /[, out, where, casting, order, ...])</code>	Return the truncated value of the input, element-wise.

`numpy. round (a, decimals=0, out=None)`

Evenly round to the given number of decimals.

Parameters

a

[array_like] Input data.

decimals

[int, optional] Number of decimal places to round to (default: 0). If *decimals* is negative, it specifies the number of positions to the left of the decimal point.

out

[ndarray, optional] Alternative output array in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary. See [ufuncs-output-type](#) for more details.

Returns**rounded_array**

[ndarray] An array of the same type as *a*, containing the rounded values. Unless *out* was specified, a new array is created. A reference to the result is returned.

The real and imaginary parts of complex numbers are rounded separately. The result of rounding a float is a float.

See also:

[*ndarray.round*](#)

equivalent method

[*around*](#)

an alias for this function

[*ceil*](#), [*fix*](#), [*floor*](#), [*rint*](#), [*trunc*](#)

Notes

For values exactly halfway between rounded decimal values, NumPy rounds to the nearest even value. Thus 1.5 and 2.5 round to 2.0, -0.5 and 0.5 round to 0.0, etc.

`np.round` uses a fast but sometimes inexact algorithm to round floating-point datatypes. For positive *decimals* it is equivalent to `np.true_divide(np.rint(a * 10**decimals), 10**decimals)`, which has error due to the inexact representation of decimal fractions in the IEEE floating point standard [1] and errors introduced when scaling by powers of ten. For instance, note the extra “1” in the following:

```
>>> np.round(56294995342131.5, 3)
56294995342131.51
```

If your goal is to print such values with a fixed number of decimals, it is preferable to use numpy’s float printing routines to limit the number of printed decimals:

```
>>> np.format_float_positional(56294995342131.5, precision=3)
'56294995342131.5'
```

The float printing routines use an accurate but much more computationally demanding algorithm to compute the number of digits after the decimal point.

Alternatively, Python’s builtin [*round*](#) function uses a more accurate but slower algorithm for 64-bit floating point values:

```
>>> round(56294995342131.5, 3)
56294995342131.5
>>> np.round(16.055, 2), round(16.055, 2) # equals 16.054999999999997
(16.06, 16.05)
```

References

[1]

Examples

```
>>> import numpy as np
>>> np.round([0.37, 1.64])
array([0., 2.])
>>> np.round([0.37, 1.64], decimals=1)
array([0.4, 1.6])
>>> np.round([.5, 1.5, 2.5, 3.5, 4.5]) # rounds to nearest even value
array([0., 2., 2., 4., 4.])
>>> np.round([1,2,3,11], decimals=1) # ndarray of ints is returned
array([ 1,  2,  3, 11])
>>> np.round([1,2,3,11], decimals=-1)
array([ 0,  0,  0, 10])
```

`numpy.around(a, decimals=0, out=None)`

Round an array to the given number of decimals.

around is an alias of *round*.

See also:

ndarray.round

equivalent method

round

alias for this function

ceil, fix, floor, rint, trunc

`numpy.rint(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])`
`= <ufunc 'rint'>`

Round elements of the array to the nearest integer.

Parameters

x

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

out

[ndarray or scalar] Output array is same shape and type as *x*. This is a scalar if *x* is a scalar.

See also:

fix, *ceil*, *floor*, *trunc*

Notes

For values exactly halfway between rounded decimal values, NumPy rounds to the nearest even value. Thus 1.5 and 2.5 round to 2.0, -0.5 and 0.5 round to 0.0, etc.

Examples

```
>>> import numpy as np
>>> a = np.array([-1.7, -1.5, -0.2, 0.2, 1.5, 1.7, 2.0])
>>> np.rint(a)
array([-2., -2., -0.,  0.,  2.,  2.,  2.] )
```

`numpy.rint(x, out=None)`

Round to nearest integer towards zero.

Deprecated since version 2.5: `numpy.fix` is deprecated. Use `numpy.trunc` instead, which is faster and follows the Array API standard.

Round an array of floats element-wise to nearest integer towards zero. The rounded values have the same data-type as the input.

Parameters

x

[array_like] An array to be rounded

out

[ndarray, optional] A location into which the result is stored. If provided, it must have a shape that the input broadcasts to. If not provided or None, a freshly-allocated array is returned.

Returns

out

[ndarray of floats] An array with the same dimensions and data-type as the input. If second argument is not supplied then a new array is returned with the rounded values.

If a second argument is supplied the result is stored there. The return value `out` is then a reference to that array.

See also:

rint, *trunc*, *floor*, *ceil*
around

Round to given number of decimals

Examples

```
>>> import numpy as np
>>> np.fix(3.14)
3.0
>>> np.fix(3)
3
>>> np.fix([2.1, 2.9, -2.1, -2.9])
array([ 2.,  2., -2., -2.]
```

`numpy.floor(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'floor'>`

Return the floor of the input, element-wise.

The floor of the scalar x is the largest integer i , such that $i \leq x$. It is often denoted as $\lfloor x \rfloor$.

Parameters

x

[array_like] Input data.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray or scalar] The floor of each element in *x*. This is a scalar if *x* is a scalar.

See also:

[ceil](#), [trunc](#), [rint](#), [fix](#)

Notes

Some spreadsheet programs calculate the “floor-towards-zero”, where `floor(-2.5) == -2`. NumPy instead uses the definition of `floor` where `floor(-2.5) == -3`. The “floor-towards-zero” function is called `fix` in NumPy.

Examples

```
>>> import numpy as np
>>> a = np.array([-1.7, -1.5, -0.2, 0.2, 1.5, 1.7, 2.0])
>>> np.floor(a)
array([-2., -2., -1., 0., 1., 1., 2.]
```

`numpy.ceil(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])`
= <ufunc 'ceil'>

Return the ceiling of the input, element-wise.

The ceil of the scalar x is the smallest integer i , such that $i \geq x$. It is often denoted as $\lceil x \rceil$.

Parameters

x

[array_like] Input data.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray or scalar] The ceiling of each element in *x*. This is a scalar if *x* is a scalar.

See also:

[floor](#), [trunc](#), [rint](#), [fix](#)

Examples

```
>>> import numpy as np
```

```
>>> a = np.array([-1.7, -1.5, -0.2, 0.2, 1.5, 1.7, 2.0])
>>> np.ceil(a)
array([-1., -1., -0., 1., 2., 2., 2.]
```

`numpy.trunc(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])`
= <ufunc 'trunc'>

Return the truncated value of the input, element-wise.

The truncated value of the scalar x is the nearest integer i which is closer to zero than x is. In short, the fractional part of the signed number x is discarded.

Parameters

x
[array_like] Input data.

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where
[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**
For other keyword-only arguments, see the [ufunc docs](#).

Returns

y
[ndarray or scalar] The truncated value of each element in *x*. This is a scalar if *x* is a scalar.

See also:

[ceil](#), [floor](#), [rint](#), [fix](#)

Examples

```
>>> import numpy as np
>>> a = np.array([-1.7, -1.5, -0.2, 0.2, 1.5, 1.7, 2.0])
>>> np.trunc(a)
array([-1., -1., -0.,  0.,  1.,  1.,  2.])
```

Sums, products, differences

<code>prod(a[, axis, dtype, out, keepdims, ...])</code>	Return the product of array elements over a given axis.
<code>sum(a[, axis, dtype, out, keepdims, ...])</code>	Sum of array elements over a given axis.
<code>nanprod(a[, axis, dtype, out, keepdims, ...])</code>	Return the product of array elements over a given axis treating Not a Numbers (NaNs) as ones.
<code>nansum(a[, axis, dtype, out, keepdims, ...])</code>	Return the sum of array elements over a given axis treating Not a Numbers (NaNs) as zero.
<code>cumulative_sum(x, /, *[, axis, dtype, out, ...])</code>	Return the cumulative sum of the elements along a given axis.
<code>cumulative_prod(x, /, *[, axis, dtype, out, ...])</code>	Return the cumulative product of elements along a given axis.
<code>cumprod(a[, axis, dtype, out])</code>	Return the cumulative product of elements along a given axis.
<code>cumsum(a[, axis, dtype, out])</code>	Return the cumulative sum of the elements along a given axis.
<code>nancumprod(a[, axis, dtype, out])</code>	Return the cumulative product of array elements over a given axis treating Not a Numbers (NaNs) as one.
<code>nancumsum(a[, axis, dtype, out])</code>	Return the cumulative sum of array elements over a given axis treating Not a Numbers (NaNs) as zero.
<code>diff(a[, n, axis, prepend, append])</code>	Calculate the n-th discrete difference along the given axis.
<code>ediff1d(ary[, to_end, to_begin])</code>	The differences between consecutive elements of an array.
<code>gradient(f, *varargs[, axis, edge_order])</code>	Return the gradient of an N-dimensional array.
<code>cross(a, b[, axisa, axisb, axisc, axis])</code>	Return the cross product of two (arrays of) vectors.
<code>trapezoid(y[, x, dx, axis])</code>	Integrate along the given axis using the composite trapezoidal rule.

`numpy.prod(a, axis=None, dtype=None, out=None, keepdims=<no value>, initial=<no value>, where=<no value>)`

Return the product of array elements over a given axis.

Parameters**a**

[array_like] Input data.

axis

[None or int or tuple of ints, optional] Axis or axes along which a product is performed. The default, axis=None, will calculate the product of all the elements in the input array. If axis is negative it counts from the last to the first axis.

If axis is a tuple of ints, a product is performed on all of the axes specified in the tuple instead of a single axis or all the axes as before.

dtype

[dtype, optional] The type of the returned array, as well as of the accumulator in which the elements are multiplied. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.

out

[ndarray, optional] Alternative output array in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as di-

mensions with size one. With this option, the result will broadcast correctly against the input array.

If the default value is passed, then *keepdims* will not be passed through to the *prod* method of sub-classes of *ndarray*, however any non-default value will be. If the sub-class' method does not implement *keepdims* any exceptions will be raised.

initial

[scalar, optional] The starting value for this product. See *reduce* for details.

where

[array_like of bool, optional] Elements to include in the product. See *reduce* for details.

Returns

product_along_axis

[ndarray, see *dtype* parameter above.] An array shaped as *a* but with the specified axis removed. Returns a reference to *out* if specified.

See also:

ndarray.prod

equivalent method

ufuncs-output-type

Notes

Arithmetic is modular when using integer types, and no error is raised on overflow. That means that, on a 32-bit platform:

```
>>> x = np.array([536870910, 536870910, 536870910, 536870910])
>>> np.prod(x)
16 # may vary
```

The product of an empty array is the neutral element 1:

```
>>> np.prod([])
1.0
```

Examples

By default, calculate the product of all elements:

```
>>> import numpy as np
>>> np.prod([1., 2.])
2.0
```

Even when the input array is two-dimensional:

```
>>> a = np.array([[1., 2.], [3., 4.]])
>>> np.prod(a)
24.0
```

But we can also specify the axis over which to multiply:

```
>>> np.prod(a, axis=1)
array([ 2., 12.])
>>> np.prod(a, axis=0)
array([3., 8.])
```

Or select specific elements to include:

```
>>> np.prod([1., np.nan, 3.], where=[True, False, True])
3.0
```

If the type of *x* is unsigned, then the output type is the unsigned platform integer:

```
>>> x = np.array([1, 2, 3], dtype=np.uint8)
>>> np.prod(x).dtype == np.uint
True
```

If *x* is of a signed integer type, then the output type is the default platform integer:

```
>>> x = np.array([1, 2, 3], dtype=np.int8)
>>> np.prod(x).dtype == int
True
```

You can also start the product with a value other than one:

```
>>> np.prod([1, 2], initial=5)
10
```

`numpy.sum(a, axis=None, dtype=None, out=None, keepdims=<no value>, initial=<no value>, where=<no value>)`

Sum of array elements over a given axis.

Parameters

a

[array_like] Elements to sum.

axis

[None or int or tuple of ints, optional] Axis or axes along which a sum is performed. The default, `axis=None`, will sum all of the elements of the input array. If `axis` is negative it counts from the last to the first axis. If `axis` is a tuple of ints, a sum is performed on all of the axes specified in the tuple instead of a single axis or all the axes as before.

dtype

[dtype, optional] The type of the returned array and of the accumulator in which the elements are summed. The dtype of *a* is used by default unless *a* has an integer dtype of less precision than the default platform integer. In that case, if *a* is signed then the platform integer is used while if *a* is unsigned then an unsigned integer of the same precision as the platform integer is used.

out

[ndarray, optional] Alternative output array in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

keepdims

[bool, optional] If this is set to `True`, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.

If the default value is passed, then *keepdims* will not be passed through to the *sum* method of sub-classes of *ndarray*, however any non-default value will be. If the sub-class' method does not implement *keepdims* any exceptions will be raised.

initial

[scalar, optional] Starting value for the sum. See *reduce* for details.

where

[array_like of bool, optional] Elements to include in the sum. See *reduce* for details.

Returns

sum_along_axis

[ndarray] An array with the same shape as *a*, with the specified axis removed. If *a* is a 0-d array, or if *axis* is None, a scalar is returned. If an output array is specified, a reference to *out* is returned.

See also:

ndarray.sum

Equivalent method.

add

`numpy.add.reduce` equivalent function.

cumsum

Cumulative sum of array elements.

trapezoid

Integration of array values using composite trapezoidal rule.

mean, average

Notes

Arithmetic is modular when using integer types, and no error is raised on overflow.

The sum of an empty array is the neutral element 0:

```
>>> np.sum([])
0.0
```

For floating point numbers the numerical precision of `sum` (and `np.add.reduce`) is in general limited by directly adding each number individually to the result causing rounding errors in every step. However, often numpy will use a numerically better approach (partial pairwise summation) leading to improved precision in many use-cases. This improved precision is always provided when no *axis* is given. When *axis* is given, it will depend on which axis is summed. Technically, to provide the best speed possible, the improved precision is only used when the summation is along the fast axis in memory. Note that the exact precision may vary depending on other parameters. In contrast to NumPy, Python's `math.fsum` function uses a slower but more precise approach to summation. Especially when summing a large number of lower precision floating point numbers, such as `float32`, numerical errors can become significant. In such cases it can be advisable to use `dtype=np.float64` to use a higher precision for the output.

Examples

```
>>> import numpy as np
>>> np.sum([0.5, 1.5])
2.0
>>> np.sum([0.5, 0.7, 0.2, 1.5], dtype=np.int32)
np.int32(1)
>>> np.sum([[0, 1], [0, 5]])
6
>>> np.sum([[0, 1], [0, 5]], axis=0)
array([0, 6])
>>> np.sum([[0, 1], [0, 5]], axis=1)
array([1, 5])
>>> np.sum([[0, 1], [np.nan, 5]], where=[False, True], axis=1)
array([1., 5.])
```

If the accumulator is too small, overflow occurs:

```
>>> np.ones(128, dtype=np.int8).sum(dtype=np.int8)
np.int8(-128)
```

You can also start the sum with a value other than zero:

```
>>> np.sum([10], initial=5)
15
```

`numpy.nanprod(a, axis=None, dtype=None, out=None, keepdims=<no value>, initial=<no value>, where=<no value>)`

Return the product of array elements over a given axis treating Not a Numbers (NaNs) as ones.

One is returned for slices that are all-NaN or empty.

Parameters

a

[array_like] Array containing numbers whose product is desired. If *a* is not an array, a conversion is attempted.

axis

[{int, tuple of int, None}, optional] Axis or axes along which the product is computed. The default is to compute the product of the flattened array.

dtype

[data-type, optional] The type of the returned array and of the accumulator in which the elements are summed. By default, the dtype of *a* is used. An exception is when *a* has an integer type with less precision than the platform (u)intp. In that case, the default will be either (u)int32 or (u)int64 depending on whether the platform is 32 or 64 bits. For inexact inputs, dtype must be inexact.

out

[ndarray, optional] Alternate output array in which to place the result. The default is None. If provided, it must have the same shape as the expected output, but the type will be cast if necessary. See `ufuncs-output-type` for more details. The casting of NaN to integer can yield unexpected results.

keepdims

[bool, optional] If True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *arr*.

initial

[scalar, optional] The starting value for this product. See [reduce](#) for details.

New in version 1.22.0.

where

[array_like of bool, optional] Elements to include in the product. See [reduce](#) for details.

New in version 1.22.0.

Returns**nanprod**

[ndarray] A new array holding the result is returned unless *out* is specified, in which case it is returned.

See also:**[numpy.prod](#)**

Product across array propagating NaNs.

[isnan](#)

Show which elements are NaN.

Examples

```
>>> import numpy as np
>>> np.nanprod(1)
1
>>> np.nanprod([1])
1
>>> np.nanprod([1, np.nan])
1.0
>>> a = np.array([[1, 2], [3, np.nan]])
>>> np.nanprod(a)
6.0
>>> np.nanprod(a, axis=0)
array([3., 2.])
```

`numpy.nansum(a, axis=None, dtype=None, out=None, keepdims=<no value>, initial=<no value>, where=<no value>)`

Return the sum of array elements over a given axis treating Not a Numbers (NaNs) as zero.

In NumPy versions <= 1.9.0 Nan is returned for slices that are all-NaN or empty. In later versions zero is returned.

Parameters**a**

[array_like] Array containing numbers whose sum is desired. If *a* is not an array, a conversion is attempted.

axis

[{int, tuple of int, None}, optional] Axis or axes along which the sum is computed. The default is to compute the sum of the flattened array.

dtype

[data-type, optional] The type of the returned array and of the accumulator in which the elements are summed. By default, the dtype of *a* is used. An exception is when *a* has an integer type with less precision than the platform (u)intp. In that case, the default will be either (u)int32

or (u)int64 depending on whether the platform is 32 or 64 bits. For inexact inputs, dtype must be inexact.

out

[ndarray, optional] Alternate output array in which to place the result. The default is `None`. If provided, it must have the same shape as the expected output, but the type will be cast if necessary. See `ufuncs-output-type` for more details. The casting of NaN to integer can yield unexpected results.

keepdims

[bool, optional] If this is set to `True`, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *a*.

If the value is anything but the default, then *keepdims* will be passed through to the `mean` or `sum` methods of sub-classes of `ndarray`. If the sub-classes methods does not implement *keepdims* any exceptions will be raised.

initial

[scalar, optional] Starting value for the sum. See `reduce` for details.

New in version 1.22.0.

where

[array_like of bool, optional] Elements to include in the sum. See `reduce` for details.

New in version 1.22.0.

Returns**nansum**

[ndarray.] A new array holding the result is returned unless *out* is specified, in which it is returned. The result has the same size as *a*, and the same shape as *a* if *axis* is not `None` or *a* is a 1-d array.

See also:**`numpy.sum`**

Sum across array propagating NaNs.

`isnan`

Show which elements are NaN.

`isfinite`

Show which elements are not NaN or +/-inf.

Notes

If both positive and negative infinity are present, the sum will be Not A Number (NaN).

Examples

```
>>> import numpy as np
>>> np.nansum(1)
1
>>> np.nansum([1])
1
>>> np.nansum([1, np.nan])
1.0
>>> a = np.array([[1, 1], [1, np.nan]])
>>> np.nansum(a)
3.0
>>> np.nansum(a, axis=0)
array([2., 1.])
>>> np.nansum([1, np.nan, np.inf])
inf
>>> np.nansum([1, np.nan, -np.inf])
-inf
>>> with np.errstate(invalid="ignore"):
...     np.nansum([1, np.nan, np.inf, -np.inf]) # both +/- infinity present
np.float64(nan)
```

`numpy.cumulative_sum(x, /, *, axis=None, dtype=None, out=None, include_initial=False)`

Return the cumulative sum of the elements along a given axis.

This function is an Array API compatible alternative to `numpy.cumsum`.

Parameters

x

[array_like] Input array.

axis

[int, optional] Axis along which the cumulative sum is computed. The default (None) is only allowed for one-dimensional arrays. For arrays with more than one dimension `axis` is required.

dtype

[dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If `dtype` is not specified, it defaults to the dtype of `x`, unless `x` has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

out

[ndarray, optional] Alternative output array in which to place the result. It must have the same shape and buffer length as the expected output but the type will be cast if necessary. See `ufuncs-output-type` for more details.

include_initial

[bool, optional] Boolean indicating whether to include the initial value (zeros) as the first value in the output. With `include_initial=True` the shape of the output is different than the shape of the input. Default: `False`.

Returns

cumulative_sum_along_axis

[ndarray] A new array holding the result is returned unless `out` is specified, in which case a reference to `out` is returned. The result has the same shape as `x` if `include_initial=False`.

See also:

sum

Sum array elements.

trapezoid

Integration of array values using composite trapezoidal rule.

diff

Calculate the n-th discrete difference along given axis.

Notes

Arithmetic is modular when using integer types, and no error is raised on overflow.

`cumulative_sum(a)[-1]` may not be equal to `sum(a)` for floating-point values since `sum` may use a pair-wise summation routine, reducing the roundoff-error. See [sum](#) for more information.

Examples

```
>>> a = np.array([1, 2, 3, 4, 5, 6])
>>> a
array([1, 2, 3, 4, 5, 6])
>>> np.cumulative_sum(a)
array([ 1,  3,  6, 10, 15, 21])
>>> np.cumulative_sum(a, dtype=np.float64)  # specifies type of output value(s)
array([ 1.,  3.,  6., 10., 15., 21.]
```

```
>>> b = np.array([[1, 2, 3], [4, 5, 6]])
>>> np.cumulative_sum(b,axis=0)  # sum over rows for each of the 3 columns
array([[1, 2, 3],
       [5, 7, 9]])
>>> np.cumulative_sum(b,axis=1)  # sum over columns for each of the 2 rows
array([[ 1,  3,  6],
       [ 4,  9, 15]])
```

`cumulative_sum(c)[-1]` may not be equal to `sum(c)`

```
>>> c = np.array([1, 2e-9, 3e-9] * 1000000)
>>> np.cumulative_sum(c)[-1]
1000000.0050045159
>>> c.sum()
1000000.0050000029
```

`numpy.cumulative_prod(x, /, *, axis=None, dtype=None, out=None, include_initial=False)`

Return the cumulative product of elements along a given axis.

This function is an Array API compatible alternative to `numpy.cumprod`.

Parameters

x

[array_like] Input array.

axis

[int, optional] Axis along which the cumulative product is computed. The default (None) is

only allowed for one-dimensional arrays. For arrays with more than one dimension `axis` is required.

dtype

[dtype, optional] Type of the returned array, as well as of the accumulator in which the elements are multiplied. If `dtype` is not specified, it defaults to the dtype of `x`, unless `x` has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used instead.

out

[ndarray, optional] Alternative output array in which to place the result. It must have the same shape and buffer length as the expected output but the type of the resulting values will be cast if necessary. See `ufuncs-output-type` for more details.

include_initial

[bool, optional] Boolean indicating whether to include the initial value (ones) as the first value in the output. With `include_initial=True` the shape of the output is different than the shape of the input. Default: `False`.

Returns

cumulative_prod_along_axis

[ndarray] A new array holding the result is returned unless `out` is specified, in which case a reference to `out` is returned. The result has the same shape as `x` if `include_initial=False`.

Notes

Arithmetic is modular when using integer types, and no error is raised on overflow.

Examples

```
>>> a = np.array([1, 2, 3])
>>> np.cumulative_prod(a)  # intermediate results 1, 1*2
...                        # total product 1*2*3 = 6
array([1, 2, 6])
>>> a = np.array([1, 2, 3, 4, 5, 6])
>>> np.cumulative_prod(a, dtype=np.float64) # specify type of output
array([ 1.,  2.,  6., 24., 120., 720.])
```

The cumulative product for each column (i.e., over the rows) of `b`:

```
>>> b = np.array([[1, 2, 3], [4, 5, 6]])
>>> np.cumulative_prod(b, axis=0)
array([[ 1,  2,  3],
       [ 4, 10, 18]])
```

The cumulative product for each row (i.e. over the columns) of `b`:

```
>>> np.cumulative_prod(b, axis=1)
array([[ 1,  2,  6],
       [ 4, 20, 120]])
```

`numpy.cumprod(a, axis=None, dtype=None, out=None)`

Return the cumulative product of elements along a given axis.

Parameters

- a**
[array_like] Input array.
- axis**
[int, optional] Axis along which the cumulative product is computed. By default the input is flattened.
- dtype**
[dtype, optional] Type of the returned array, as well as of the accumulator in which the elements are multiplied. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used instead.
- out**
[ndarray, optional] Alternative output array in which to place the result. It must have the same shape and buffer length as the expected output but the type of the resulting values will be cast if necessary.

Returns

- cumprod**
[ndarray] A new array holding the result is returned unless *out* is specified, in which case a reference to *out* is returned.

See also:*[cumulative_prod](#)*

Array API compatible alternative for `cumprod`.

ufuncs-output-type**Notes**

Arithmetic is modular when using integer types, and no error is raised on overflow.

Examples

```
>>> import numpy as np
>>> a = np.array([1,2,3])
>>> np.cumprod(a) # intermediate results 1, 1*2
...             # total product 1*2*3 = 6
array([1, 2, 6])
>>> a = np.array([[1, 2, 3], [4, 5, 6]])
>>> np.cumprod(a, dtype=np.float64) # specify type of output
array([ 1.,  2.,  6., 24., 120., 720.])
```

The cumulative product for each column (i.e., over the rows) of *a*:

```
>>> np.cumprod(a, axis=0)
array([[ 1,  2,  3],
       [ 4, 10, 18]])
```

The cumulative product for each row (i.e. over the columns) of *a*:

```
>>> np.cumprod(a, axis=1)
array([[ 1,  2,  6],
       [ 4, 20, 120]])
```

`numpy.cumsum(a, axis=None, dtype=None, out=None)`

Return the cumulative sum of the elements along a given axis.

Parameters

a

[array_like] Input array.

axis

[int, optional] Axis along which the cumulative sum is computed. The default (None) is to compute the cumsum over the flattened array.

dtype

[dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

out

[ndarray, optional] Alternative output array in which to place the result. It must have the same shape and buffer length as the expected output but the type will be cast if necessary. See *ufuncs-output-type* for more details.

Returns

cumsum_along_axis

[ndarray.] A new array holding the result is returned unless *out* is specified, in which case a reference to *out* is returned. The result has the same size as *a*, and the same shape as *a* if *axis* is not None or *a* is a 1-d array.

See also:

cumulative_sum

Array API compatible alternative for *cumsum*.

sum

Sum array elements.

trapezoid

Integration of array values using composite trapezoidal rule.

diff

Calculate the n-th discrete difference along given axis.

Notes

Arithmetic is modular when using integer types, and no error is raised on overflow.

`cumsum(a) [-1]` may not be equal to `sum(a)` for floating-point values since *sum* may use a pairwise summation routine, reducing the roundoff-error. See *sum* for more information.

Examples

```
>>> import numpy as np
>>> a = np.array([[1,2,3], [4,5,6]])
>>> a
array([[1, 2, 3],
       [4, 5, 6]])
>>> np.cumsum(a)
array([ 1,  3,  6, 10, 15, 21])
>>> np.cumsum(a, dtype=np.float64) # specifies type of output value(s)
array([ 1.,  3.,  6., 10., 15., 21.])
```

```
>>> np.cumsum(a,axis=0) # sum over rows for each of the 3 columns
array([[1, 2, 3],
       [5, 7, 9]])
>>> np.cumsum(a,axis=1) # sum over columns for each of the 2 rows
array([[ 1,  3,  6],
       [ 4,  9, 15]])
```

`cumsum(b) [-1]` may not be equal to `sum(b)`

```
>>> b = np.array([1, 2e-9, 3e-9] * 1000000)
>>> b.cumsum() [-1]
1000000.0050045159
>>> b.sum()
1000000.0050000029
```

`numpy.nancumprod` (*a*, *axis=None*, *dtype=None*, *out=None*)

Return the cumulative product of array elements over a given axis treating Not a Numbers (NaNs) as one. The cumulative product does not change when NaNs are encountered and leading NaNs are replaced by ones.

Ones are returned for slices that are all-NaN or empty.

Parameters

a

[array_like] Input array.

axis

[int, optional] Axis along which the cumulative product is computed. By default the input is flattened.

dtype

[dtype, optional] Type of the returned array, as well as of the accumulator in which the elements are multiplied. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used instead.

out

[ndarray, optional] Alternative output array in which to place the result. It must have the same shape and buffer length as the expected output but the type of the resulting values will be cast if necessary.

Returns

nancumprod

[ndarray] A new array holding the result is returned unless *out* is specified, in which case it is returned.

See also:

`numpy.cumprod`

Cumulative product across array propagating NaNs.

`isnan`

Show which elements are NaN.

Examples

```
>>> import numpy as np
>>> np.nancumprod(1)
array([1])
>>> np.nancumprod([1])
array([1])
>>> np.nancumprod([1, np.nan])
array([1.,  1.])
>>> a = np.array([[1, 2], [3, np.nan]])
>>> np.nancumprod(a)
array([1.,  2.,  6.,  6.])
>>> np.nancumprod(a, axis=0)
array([[1.,  2.],
       [3.,  2.]])
>>> np.nancumprod(a, axis=1)
array([[1.,  2.],
       [3.,  3.]])
```

`numpy.nancumsum` (*a*, *axis=None*, *dtype=None*, *out=None*)

Return the cumulative sum of array elements over a given axis treating Not a Numbers (NaNs) as zero. The cumulative sum does not change when NaNs are encountered and leading NaNs are replaced by zeros.

Zeros are returned for slices that are all-NaN or empty.

Parameters

a

[array_like] Input array.

axis

[int, optional] Axis along which the cumulative sum is computed. The default (None) is to compute the cumsum over the flattened array.

dtype

[dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

out

[ndarray, optional] Alternative output array in which to place the result. It must have the same shape and buffer length as the expected output but the type will be cast if necessary. See `ufuncs-output-type` for more details.

Returns

nancumsum

[ndarray.] A new array holding the result is returned unless *out* is specified, in which it is returned. The result has the same size as *a*, and the same shape as *a* if *axis* is not None or *a* is a 1-d array.

See also:

[`numpy.cumsum`](#)

Cumulative sum across array propagating NaNs.

[`isnan`](#)

Show which elements are NaN.

Examples

```
>>> import numpy as np
>>> np.nancumsum(1)
array([1])
>>> np.nancumsum([1])
array([1])
>>> np.nancumsum([1, np.nan])
array([1.,  1.])
>>> a = np.array([[1, 2], [3, np.nan]])
>>> np.nancumsum(a)
array([1.,  3.,  6.,  6.])
>>> np.nancumsum(a, axis=0)
array([[1.,  2.],
       [4.,  2.]])
>>> np.nancumsum(a, axis=1)
array([[1.,  3.],
       [3.,  3.]])
```

`numpy.diff(a, n=1, axis=-1, prepend=<no value>, append=<no value>)`

Calculate the n -th discrete difference along the given axis.

The first difference is given by $\text{out}[i] = a[i+1] - a[i]$ along the given axis, higher differences are calculated by using `diff` recursively.

Parameters

a

[array_like] Input array

n

[int, optional] The number of times values are differenced. If zero, the input is returned as-is.

axis

[int, optional] The axis along which the difference is taken, default is the last axis.

prepend, append

[array_like, optional] Values to prepend or append to *a* along axis prior to performing the difference. Scalar values are expanded to arrays with length 1 in the direction of axis and the shape of the input array in along all other axes. Otherwise the dimension and shape must match *a* except along axis.

Returns

diff

[ndarray] The n -th differences. The shape of the output is the same as *a* except along *axis* where the dimension is smaller by *n*. The type of the output is the same as the type of the difference between any two elements of *a*. This is the same as the type of *a* in most cases. A notable exception is `datetime64`, which results in a `timedelta64` output array.

See also:

gradient, ediff1d, cumsum

Notes

Type is preserved for boolean arrays, so the result will contain *False* when consecutive elements are the same and *True* when they differ.

For unsigned integer arrays, the results will also be unsigned. This should not be surprising, as the result is consistent with calculating the difference directly:

```
>>> u8_arr = np.array([1, 0], dtype=np.uint8)
>>> np.diff(u8_arr)
array([255], dtype=uint8)
>>> u8_arr[1,...] - u8_arr[0,...]
np.uint8(255)
```

If this is not desirable, then the array should be cast to a larger integer type first:

```
>>> i16_arr = u8_arr.astype(np.int16)
>>> np.diff(i16_arr)
array([-1], dtype=int16)
```

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 4, 7, 0])
>>> np.diff(x)
array([ 1,  2,  3, -7])
>>> np.diff(x, n=2)
array([ 1,  1, -10])
```

```
>>> x = np.array([[1, 3, 6, 10], [0, 5, 6, 8]])
>>> np.diff(x)
array([[2, 3, 4],
       [5, 1, 2]])
>>> np.diff(x, axis=0)
array([[ -1,  2,  0, -2]])
```

```
>>> x = np.arange('1066-10-13', '1066-10-16', dtype=np.datetime64)
>>> np.diff(x)
array([1, 1], dtype='timedelta64[D]')
```

`numpy.ediff1d(ary, to_end=None, to_begin=None)`

The differences between consecutive elements of an array.

Parameters

ary

[array_like] If necessary, will be flattened before the differences are taken.

to_end

[array_like, optional] Number(s) to append at the end of the returned differences.

to_begin

[array_like, optional] Number(s) to prepend at the beginning of the returned differences.

Returns**ediff1d**

[ndarray] The differences. Loosely, this is `ary.flat[1:] - ary.flat[:-1]`.

See also:

diff, gradient

Notes

When applied to masked arrays, this function drops the mask information if the *to_begin* and/or *to_end* parameters are used.

Examples

```
>>> import numpy as np
>>> x = np.array([1, 2, 4, 7, 0])
>>> np.ediff1d(x)
array([ 1,  2,  3, -7])
```

```
>>> np.ediff1d(x, to_begin=-99, to_end=np.array([88, 99]))
array([-99,   1,   2, ..., -7,  88,  99])
```

The returned array is always 1D.

```
>>> y = [[1, 2, 4], [1, 6, 24]]
>>> np.ediff1d(y)
array([ 1,  2, -3,  5, 18])
```

`numpy.gradient` (*f*, **varargs*, *axis=None*, *edge_order=1*)

Return the gradient of an N-dimensional array.

The gradient is computed using second order accurate central differences in the interior points and either first or second order accurate one-sides (forward or backwards) differences at the boundaries. The returned gradient hence has the same shape as the input array.

Parameters**f**

[array_like] An N-dimensional array containing samples of a scalar function.

varargs

[list of scalar or array, optional] Spacing between *f* values. Default unitary spacing for all dimensions. Spacing can be specified using:

1. Single scalar to specify a sample distance for all dimensions.
2. N scalars to specify a constant sample distance for each dimension. i.e. *dx*, *dy*, *dz*, ...
3. N arrays to specify the coordinates of the values along each dimension of *F*. The length of the array must match the size of the corresponding dimension
4. Any combination of N scalars/arrays with the meaning of 2. and 3.

If *axis* is given, the number of *varargs* must equal the number of axes specified in the *axis* parameter. Default: 1. (see Examples below).

edge_order

[[1, 2], optional] Gradient is calculated using N-th order accurate differences at the boundaries.
Default: 1.

axis

[None or int or tuple of ints, optional] Gradient is calculated only along the given axis or axes. The default (axis = None) is to calculate the gradient for all the axes of the input array. axis may be negative, in which case it counts from the last to the first axis.

Returns**gradient**

[ndarray or tuple of ndarray] A tuple of ndarrays (or a single ndarray if there is only one dimension) corresponding to the derivatives of f with respect to each dimension. Each derivative has the same shape as f.

Notes

Assuming that $f \in C^3$ (i.e., f has at least 3 continuous derivatives) and let h_* be a non-homogeneous stepsize, we minimize the “consistency error” η_i between the true gradient and its estimate from a linear combination of the neighboring grid-points:

$$\eta_i = f_i^{(1)} - [\alpha f(x_i) + \beta f(x_i + h_d) + \gamma f(x_i - h_s)]$$

By substituting $f(x_i + h_d)$ and $f(x_i - h_s)$ with their Taylor series expansion, this translates into solving the following the linear system:

$$\begin{cases} \alpha + \beta + \gamma = 0 \\ \beta h_d - \gamma h_s = 1 \\ \beta h_d^2 + \gamma h_s^2 = 0 \end{cases}$$

The resulting approximation of $f_i^{(1)}$ is the following:

$$\hat{f}_i^{(1)} = \frac{h_s^2 f(x_i + h_d) + (h_d^2 - h_s^2) f(x_i) - h_d^2 f(x_i - h_s)}{h_s h_d (h_d + h_s)} + \mathcal{O}\left(\frac{h_d h_s^2 + h_s h_d^2}{h_d + h_s}\right)$$

It is worth noting that if $h_s = h_d$ (i.e., data are evenly spaced) we find the standard second order approximation:

$$\hat{f}_i^{(1)} = \frac{f(x_{i+1}) - f(x_{i-1}))}{2h} + \mathcal{O}(h^2)$$

With a similar procedure the forward/backward approximations used for boundaries can be derived.

References

[1], [2], [3]

Examples

```
>>> import numpy as np
>>> f = np.array([1, 2, 4, 7, 11, 16])
>>> np.gradient(f)
array([1. , 1.5, 2.5, 3.5, 4.5, 5. ])
>>> np.gradient(f, 2)
array([0.5 , 0.75, 1.25, 1.75, 2.25, 2.5 ])
```

Spacing can be also specified with an array that represents the coordinates of the values F along the dimensions. For instance a uniform spacing:

```
>>> x = np.arange(f.size)
>>> np.gradient(f, x)
array([1. , 1.5, 2.5, 3.5, 4.5, 5. ])
```

Or a non uniform one:

```
>>> x = np.array([0., 1., 1.5, 3.5, 4., 6.])
>>> np.gradient(f, x)
array([1. , 3. , 3.5, 6.7, 6.9, 2.5])
```

For two dimensional arrays, the return will be two arrays ordered by axis. In this example the first array stands for the gradient in rows and the second one in columns direction:

```
>>> np.gradient(np.array([[1, 2, 6], [3, 4, 5]]))
(array([[ 2.,  2., -1.],
        [ 2.,  2., -1.]]),
 array([[1. , 2.5, 4. ],
        [1. , 1. , 1. ]]))
```

In this example the spacing is also specified: uniform for axis=0 and non uniform for axis=1

```
>>> dx = 2.
>>> y = [1., 1.5, 3.5]
>>> np.gradient(np.array([[1, 2, 6], [3, 4, 5]]), dx, y)
(array([[ 1. ,  1. , -0.5],
        [ 1. ,  1. , -0.5]]),
 array([[2. , 2. , 2. ],
        [2. , 1.7, 0.5]]))
```

It is possible to specify how boundaries are treated using *edge_order*

```
>>> x = np.array([0, 1, 2, 3, 4])
>>> f = x**2
>>> np.gradient(f, edge_order=1)
array([1., 2., 4., 6., 7.])
>>> np.gradient(f, edge_order=2)
array([0., 2., 4., 6., 8.])
```

The *axis* keyword can be used to specify a subset of axes of which the gradient is calculated

```
>>> np.gradient(np.array([[1, 2, 6], [3, 4, 5]]), axis=0)
array([[ 2.,  2., -1.],
        [ 2.,  2., -1.]])
```

The *varargs* argument defines the spacing between sample points in the input array. It can take two forms:

1. An array, specifying coordinates, which may be unevenly spaced:

```
>>> x = np.array([0., 2., 3., 6., 8.])
>>> y = x ** 2
>>> np.gradient(y, x, edge_order=2)
array([ 0.,  4.,  6., 12., 16.] )
```

2. A scalar, representing the fixed sample distance:

```
>>> dx = 2
>>> x = np.array([0., 2., 4., 6., 8.])
>>> y = x ** 2
>>> np.gradient(y, dx, edge_order=2)
array([ 0.,  4.,  8., 12., 16.]
```

It's possible to provide different data for spacing along each dimension. The number of arguments must match the number of dimensions in the input data.

```
>>> dx = 2
>>> dy = 3
>>> x = np.arange(0, 6, dx)
>>> y = np.arange(0, 9, dy)
>>> xs, ys = np.meshgrid(x, y)
>>> zs = xs + 2 * ys
>>> np.gradient(zs, dy, dx) # Passing two scalars
(array([[2., 2., 2.],
       [2., 2., 2.],
       [2., 2., 2.]]),
 array([[1., 1., 1.],
       [1., 1., 1.],
       [1., 1., 1.]])
```

Mixing scalars and arrays is also allowed:

```
>>> np.gradient(zs, y, dx) # Passing one array and one scalar
(array([[2., 2., 2.],
       [2., 2., 2.],
       [2., 2., 2.]]),
 array([[1., 1., 1.],
       [1., 1., 1.],
       [1., 1., 1.]])
```

`numpy.cross(a, b, axisa=-1, axisb=-1, axisc=-1, axis=None)`

Return the cross product of two (arrays of) vectors.

The cross product of a and b in R^3 is a vector perpendicular to both a and b . If a and b are arrays of vectors, the vectors are defined by the last axis of a and b by default, and these axes must have 3 dimensions.

Parameters

a

[array_like] Components of the first vector(s).

b

[array_like] Components of the second vector(s).

axisa

[int, optional] Axis of a that defines the vector(s). By default, the last axis.

axisb

[int, optional] Axis of b that defines the vector(s). By default, the last axis.

axisc

[int, optional] Axis of c containing the cross product vector(s). By default, the last axis.

axis

[int, optional] If defined, the axis of a , b and c that defines the vector(s) and cross product(s). Overrides *axisa*, *axisb* and *axisc*.

Returns

c
[ndarray] Vector cross product(s).

Raises**ValueError**

When the dimension of the vector(s) in *a* or *b* does not equal 3.

See also:*inner*

Inner product

outer

Outer product.

linalg.cross

An Array API compatible variation of `np.cross`.

ix_

Construct index arrays.

Notes

Supports full broadcasting of the inputs.

Examples

Vector cross-product.

```
>>> import numpy as np
>>> x = [1, 2, 3]
>>> y = [4, 5, 6]
>>> np.cross(x, y)
array([-3,  6, -3])
```

One vector with dimension 2.

```
>>> x = [1, 2, 0]
>>> y = [4, 5, 6]
>>> np.cross(x, y)
array([12, -6, -3])
```

Both vectors with dimension 2.

```
>>> x = [1, 2, 0]
>>> y = [4, 5, 0]
>>> np.cross(x, y)
array([0, 0, -3])
```

Multiple vector cross-products. Note that the direction of the cross product vector is defined by the *right-hand rule*.

```
>>> x = np.array([[1,2,3], [4,5,6]])
>>> y = np.array([[4,5,6], [1,2,3]])
>>> np.cross(x, y)
array([[ -3,  6, -3],
       [ 3, -6,  3]])
```

The orientation of *c* can be changed using the *axisc* keyword.

```
>>> np.cross(x, y, axisc=0)
array([[ -3,  3],
       [ 6, -6],
       [-3,  3]])
```

Change the vector definition of *x* and *y* using *axisa* and *axisb*.

```
>>> x = np.array([[1,2,3], [4,5,6], [7, 8, 9]])
>>> y = np.array([[7, 8, 9], [4,5,6], [1,2,3]])
>>> np.cross(x, y)
array([[ -6, 12, -6],
       [ 0,  0,  0],
       [ 6, -12,  6]])
>>> np.cross(x, y, axisa=0, axisb=0)
array([[ -24, 48, -24],
       [-30, 60, -30],
       [-36, 72, -36]])
```

`numpy.trapezoid` (*y*, *x=None*, *dx=1.0*, *axis=-1*)

Integrate along the given axis using the composite trapezoidal rule.

If *x* is provided, the integration happens in sequence along its elements - they are not sorted.

Integrate $y(x)$ along each 1d slice on the given axis, compute $\int y(x)dx$. When *x* is specified, this integrates along the parametric curve, computing $\int_t y(t)dt = \int_t y(t) \frac{dx}{dt} \Big|_{x=x(t)} dt$.

New in version 2.0.0.

Parameters

y

[array_like] Input array to integrate.

x

[array_like, optional] The sample points corresponding to the *y* values. If *x* is None, the sample points are assumed to be evenly spaced *dx* apart. The default is None.

dx

[scalar, optional] The spacing between sample points when *x* is None. The default is 1.

axis

[int, optional] The axis along which to integrate.

Returns

trapezoid

[float or ndarray] Definite integral of $y = n$ -dimensional array as approximated along a single axis by the trapezoidal rule. If *y* is a 1-dimensional array, then the result is a float. If *n* is greater than 1, then the result is an $n-1$ dimensional array.

See also:

[*sum*](#), [*cumsum*](#)

Notes

Image [2] illustrates trapezoidal rule – y-axis locations of points will be taken from *y* array, by default x-axis distances between points will be 1.0, alternatively they can be provided with *x* array or with *dx* scalar. Return value will be equal to combined area under the red lines.

References

[1], [2]

Examples

```
>>> import numpy as np
```

Use the trapezoidal rule on evenly spaced points:

```
>>> np.trapezoid([1, 2, 3])
4.0
```

The spacing between sample points can be selected by either the *x* or *dx* arguments:

```
>>> np.trapezoid([1, 2, 3], x=[4, 6, 8])
8.0
>>> np.trapezoid([1, 2, 3], dx=2)
8.0
```

Using a decreasing *x* corresponds to integrating in reverse:

```
>>> np.trapezoid([1, 2, 3], x=[8, 6, 4])
-8.0
```

More generally *x* is used to integrate along a parametric curve. We can estimate the integral $\int_0^1 x^2 = 1/3$ using:

```
>>> x = np.linspace(0, 1, num=50)
>>> y = x**2
>>> np.trapezoid(y, x)
0.33340274885464394
```

Or estimate the area of a circle, noting we repeat the sample which closes the curve:

```
>>> theta = np.linspace(0, 2 * np.pi, num=1000, endpoint=True)
>>> np.trapezoid(np.cos(theta), x=np.sin(theta))
3.141571941375841
```

`np.trapezoid` can be applied along a specified axis to do multiple computations in one call:

```
>>> a = np.arange(6).reshape(2, 3)
>>> a
array([[0, 1, 2],
       [3, 4, 5]])
>>> np.trapezoid(a, axis=0)
array([1.5, 2.5, 3.5])
>>> np.trapezoid(a, axis=1)
array([2., 8.])
```

Exponents and logarithms

<code>exp(x, /[, out, where, casting, order, ...])</code>	Calculate the exponential of all elements in the input array.
<code>expm1(x, /[, out, where, casting, order, ...])</code>	Calculate $\exp(x) - 1$ for all elements in the array.
<code>exp2(x, /[, out, where, casting, order, ...])</code>	Calculate 2^{**p} for all p in the input array.
<code>log(x, /[, out, where, casting, order, ...])</code>	Natural logarithm, element-wise.
<code>log10(x, /[, out, where, casting, order, ...])</code>	Return the base 10 logarithm of the input array, element-wise.
<code>log2(x, /[, out, where, casting, order, ...])</code>	Base-2 logarithm of x .
<code>log1p(x, /[, out, where, casting, order, ...])</code>	Return the natural logarithm of one plus the input array, element-wise.
<code>logaddexp(x1, x2, /[, out, where, casting, ...])</code>	Logarithm of the sum of exponentiations of the inputs.
<code>logaddexp2(x1, x2, /[, out, where, casting, ...])</code>	Logarithm of the sum of exponentiations of the inputs in base-2.

```
numpy.exp(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
      = <ufunc 'exp'>
```

Calculate the exponential of all elements in the input array.

Parameters

x

[array_like] Input values.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Output array, element-wise exponential of x . This is a scalar if x is a scalar.

See also:

[`expm1`](#)

Calculate $\exp(x) - 1$ for all elements in the array.

[`exp2`](#)

Calculate 2^{**x} for all elements in the array.

Notes

The irrational number e is also known as Euler's number. It is approximately 2.718281, and is the base of the natural logarithm, $\ln$ (this means that, if $x = \ln y = \log_e y$, then $e^x = y$. For real input, $\exp(x)$ is always positive.

For complex arguments, $x = a + ib$, we can write $e^x = e^a e^{ib}$. The first term, e^a , is already known (it is the real argument, described above). The second term, e^{ib} , is $\cos b + i \sin b$, a function with magnitude 1 and a periodic phase.

References

[1], [2]

Examples

Plot the magnitude and phase of $\exp(x)$ in the complex plane:

```
>>> import numpy as np
```

```
>>> import matplotlib.pyplot as plt
>>> import numpy as np
```

```
>>> x = np.linspace(-2*np.pi, 2*np.pi, 100)
>>> xx = x + 1j * x[:, np.newaxis] # a + ib over complex plane
>>> out = np.exp(xx)
```

```
>>> plt.subplot(121)
>>> plt.imshow(np.abs(out),
...           extent=[-2*np.pi, 2*np.pi, -2*np.pi, 2*np.pi], cmap='gray')
>>> plt.title('Magnitude of exp(x)')
```

```
>>> plt.subplot(122)
>>> plt.imshow(np.angle(out),
...           extent=[-2*np.pi, 2*np.pi, -2*np.pi, 2*np.pi], cmap='hsv')
>>> plt.title('Phase (angle) of exp(x)')
>>> plt.show()
```

`numpy.expm1(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'expm1'>`

Calculate $\exp(x) - 1$ for all elements in the array.

Parameters

x

[array_like] Input values.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

**where**

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**out**

[ndarray or scalar] Element-wise exponential minus one: $\text{out} = \exp(x) - 1$. This is a scalar if *x* is a scalar.

See also:*log1p*

$\log(1 + x)$, the inverse of *expm1*.

Notes

This function provides greater precision than $\exp(x) - 1$ for small values of *x*.

Examples

The true value of $\exp(1\text{e-}10) - 1$ is $1.00000000005\text{e-}10$ to about 32 significant digits. This example shows the superiority of *expm1* in this case.

```
>>> import numpy as np
>>> np.expm1(1e-10)
1.000000000005e-10
>>> np.exp(1e-10) - 1
1.000000082740371e-10
```

```
numpy.exp2(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])  
= <ufunc 'exp2'>
```

Calculate 2^{**p} for all p in the input array.

Parameters

x

[array_like] Input values.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Element-wise 2 to the power x . This is a scalar if x is a scalar.

See also:

[power](#)

Examples

```
>>> import numpy as np  
>>> np.exp2([2, 3])  
array([ 4.,  8.]
```

```
numpy.log(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])  
= <ufunc 'log'>
```

Natural logarithm, element-wise.

The natural logarithm [log](#) is the inverse of the exponential function, so that $\log(\exp(x)) = x$. The natural logarithm is logarithm in base e .

Parameters

x

[array_like] Input value.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**y**

[ndarray] The natural logarithm of *x*, element-wise. This is a scalar if *x* is a scalar.

See also:

[log10](#), [log2](#), [log1p](#), [emath.log](#)

Notes

Logarithm is a multivalued function: for each *x* there is an infinite number of *z* such that $\exp(z) = x$. The convention is to return the *z* whose imaginary part lies in $(-pi, pi]$.

For real-valued input data types, [log](#) always returns real output. For each value that cannot be expressed as a real number or infinity, it yields nan and sets the *invalid* floating point error flag.

For complex-valued input, [log](#) is a complex analytical function that has a branch cut $[-inf, 0]$ and is continuous from above on it. [log](#) handles the floating-point negative zero as an infinitesimal negative number, conforming to the C99 standard.

In the cases where the input has a negative real part and a very small negative complex part (approaching 0), the result is so close to $-pi$ that it evaluates to exactly $-pi$.

References

[1], [2]

Examples

```
>>> import numpy as np
>>> np.log([1, np.e, np.e**2, 0])
array([ 0.,  1.,  2., -inf])
```

```
numpy.log10(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'log10'>
```

Return the base 10 logarithm of the input array, element-wise.

Parameters**x**

[array_like] Input values.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None,

a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] The logarithm to the base 10 of *x*, element-wise. NaNs are returned where *x* is negative. This is a scalar if *x* is a scalar.

See also:

[`emath.log10`](#)

Notes

Logarithm is a multivalued function: for each *x* there is an infinite number of *z* such that $10^{**z} = x$. The convention is to return the *z* whose imaginary part lies in $(-pi, pi]$.

For real-valued input data types, `log10` always returns real output. For each value that cannot be expressed as a real number or infinity, it yields `nan` and sets the *invalid* floating point error flag.

For complex-valued input, `log10` is a complex analytical function that has a branch cut $[-inf, 0]$ and is continuous from above on it. `log10` handles the floating-point negative zero as an infinitesimal negative number, conforming to the C99 standard.

In the cases where the input has a negative real part and a very small negative complex part (approaching 0), the result is so close to $-pi$ that it evaluates to exactly $-pi$.

References

[1], [2]

Examples

```
>>> import numpy as np
>>> np.log10([1e-15, -3.])
array([-15.,  nan])
```

```
numpy.log2(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
      = <ufunc 'log2'>
```

Base-2 logarithm of *x*.

Parameters

x

[array_like] Input values.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns**y**

[ndarray] Base-2 logarithm of *x*. This is a scalar if *x* is a scalar.

See also:

[*log*](#), [*log10*](#), [*log1p*](#), [*emath.log2*](#)

Notes

Logarithm is a multivalued function: for each *x* there is an infinite number of *z* such that $2^{**z} = x$. The convention is to return the *z* whose imaginary part lies in $(-pi, pi]$.

For real-valued input data types, *log2* always returns real output. For each value that cannot be expressed as a real number or infinity, it yields nan and sets the *invalid* floating point error flag.

For complex-valued input, *log2* is a complex analytical function that has a branch cut $[-inf, 0]$ and is continuous from above on it. *log2* handles the floating-point negative zero as an infinitesimal negative number, conforming to the C99 standard.

In the cases where the input has a negative real part and a very small negative complex part (approaching 0), the result is so close to $-pi$ that it evaluates to exactly $-pi$.

Examples

```
>>> import numpy as np
>>> x = np.array([0, 1, 2, 2**4])
>>> np.log2(x)
array([-inf,  0.,  1.,  4.])
```

```
>>> xi = np.array([0+1.j, 1, 2+0.j, 4.j])
>>> np.log2(xi)
array([ 0.+2.26618007j,  0.+0.j,  1.+0.j,  2.+2.26618007j])
```

```
numpy.log1p(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'log1p'>
```

Return the natural logarithm of one plus the input array, element-wise.

Calculates $\log(1 + x)$.

Parameters

x`[array_like]` Input values.**out**`[ndarray, None, or tuple of ndarray and None, optional]` A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or `None`, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.**where**`[array_like, optional]` This condition is broadcast over the input. At locations where the condition is `True`, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.****kwargs**For other keyword-only arguments, see the [ufunc docs](#).**Returns****y**`[ndarray]` Natural logarithm of $1 + x$, element-wise. This is a scalar if x is a scalar.**See also:**[*expm1*](#) $\exp(x) - 1$, the inverse of [*log1p*](#).**Notes**For real-valued input, [*log1p*](#) is accurate also for x so small that $1 + x == 1$ in floating-point accuracy.Logarithm is a multivalued function: for each x there is an infinite number of z such that $\exp(z) = 1 + x$. The convention is to return the z whose imaginary part lies in $[-\pi, \pi]$.For real-valued input data types, [*log1p*](#) always returns real output. For each value that cannot be expressed as a real number or infinity, it yields `nan` and sets the *invalid* floating point error flag.For complex-valued input, [*log1p*](#) is a complex analytical function that has a branch cut $[-\text{inf}, -1]$ and is continuous from above on it. [*log1p*](#) handles the floating-point negative zero as an infinitesimal negative number, conforming to the C99 standard.**References**[\[1\]](#), [\[2\]](#)**Examples**

```
>>> import numpy as np
>>> np.log1p(1e-99)
1e-99
>>> np.log(1 + 1e-99)
0.0
```

```
numpy.logaddexp(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'logaddexp'>
```

Logarithm of the sum of exponentiations of the inputs.

Calculates $\log(\exp(x1) + \exp(x2))$. This function is useful in statistics where the calculated probabilities of events may be so small as to exceed the range of normal floating point numbers. In such cases the logarithm of the calculated probability is stored. This function allows adding probabilities stored in such a fashion.

Parameters

x1, x2

[array_like] Input values. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

**kwargs

For other keyword-only arguments, see the [ufunc docs](#).

Returns

result

[ndarray] Logarithm of $\exp(x1) + \exp(x2)$. This is a scalar if both `x1` and `x2` are scalars.

See also:

[logaddexp2](#)

Logarithm of the sum of exponentiations of inputs in base 2.

Examples

```
>>> import numpy as np
>>> prob1 = np.log(1e-50)
>>> prob2 = np.log(2.5e-50)
>>> prob12 = np.logaddexp(prob1, prob2)
>>> prob12
-113.87649168120691
>>> np.exp(prob12)
3.50000000000000057e-50
```

```
numpy.logaddexp2(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'logaddexp2'>
```

Logarithm of the sum of exponentiations of the inputs in base-2.

Calculates $\log_2(2^{x1} + 2^{x2})$. This function is useful in machine learning when the calculated probabilities of events may be so small as to exceed the range of normal floating point numbers. In such cases the base-2 logarithm of the calculated probability can be used instead. This function allows adding probabilities stored in such a fashion.

Parameters**x1, x2**

[array_like] Input values. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**result**

[ndarray] Base-2 logarithm of $2^{x1} + 2^{x2}$. This is a scalar if both *x1* and *x2* are scalars.

See also:[*logaddexp*](#)

Logarithm of the sum of exponentiations of the inputs.

Examples

```
>>> import numpy as np
>>> prob1 = np.log2(1e-50)
>>> prob2 = np.log2(2.5e-50)
>>> prob12 = np.logaddexp2(prob1, prob2)
>>> prob1, prob2, prob12
(-166.09640474436813, -164.77447664948076, -164.28904982231052)
>>> 2**prob12
3.4999999999999914e-50
```

Other special functions

<code>i0(x)</code>	Modified Bessel function of the first kind, order 0.
<code>sinc(x)</code>	Return the normalized sinc function.

`numpy.i0(x)`

Modified Bessel function of the first kind, order 0.

Usually denoted I_0 .

Parameters

x
[array_like of float] Argument of the Bessel function.

Returns

out
[ndarray, shape = x.shape, dtype = float] The modified Bessel function evaluated at each of the elements of x.

See also:

`scipy.special.i0`, `scipy.special.iv`, `scipy.special.ive`

Notes

The scipy implementation is recommended over this function: it is a proper ufunc written in C, and more than an order of magnitude faster.

We use the algorithm published by Clenshaw [1] and referenced by Abramowitz and Stegun [2], for which the function domain is partitioned into the two intervals [0,8] and (8,inf), and Chebyshev polynomial expansions are employed in each interval. Relative error on the domain [0,30] using IEEE arithmetic is documented [3] as having a peak of 5.8e-16 with an rms of 1.4e-16 (n = 30000).

References

[1], [2], [3]

Examples

```
>>> import numpy as np
>>> np.i0(0.)
array(1.0)
>>> np.i0([0, 1, 2, 3])
array([1.          , 1.26606588, 2.2795853 , 4.88079259])
```

`numpy.sinc(x)`

Return the normalized sinc function.

The sinc function is equal to $\sin(\pi x)/(\pi x)$ for any argument $x \neq 0$. `sinc(0)` takes the limit value 1, making `sinc` not only everywhere continuous but also infinitely differentiable.

Note: Note the normalization factor of `pi` used in the definition. This is the most commonly used definition in signal processing. Use `sinc(x / np.pi)` to obtain the unnormalized sinc function $\sin(x)/x$ that is more common in mathematics.

Parameters

x
[ndarray] Array (possibly multi-dimensional) of values for which to calculate `sinc(x)`.

Returns

out
[ndarray] `sinc(x)`, which has the same shape as the input.

Notes

The name `sinc` is short for “sine cardinal” or “sinus cardinalis”.

The `sinc` function is used in various signal processing applications, including in anti-aliasing, in the construction of a Lanczos resampling filter, and in interpolation.

For bandlimited interpolation of discrete-time signals, the ideal interpolation kernel is proportional to the `sinc` function.

Array API Standard Support

`sinc` has experimental support for Python Array API Standard compatible backends in addition to NumPy. Please consider testing these features by setting an environment variable `SCIPY_ARRAY_API=1` and providing CuPy, PyTorch, JAX, or Dask arrays as array arguments. The following combinations of backend and device (or other capability) are supported.

Library	CPU	GPU
NumPy	✓	n/a
CuPy	n/a	✓
PyTorch	✓	✓
JAX	✓	⊖
Dask	✓	n/a

See [Support for the array API standard](#) for more information.

Text(0.5, 0, 'X')
>>> plt.show()
```

Floating point routines

<code>signbit(x, /[, out, where, casting, order, ...])</code>	Returns element-wise True where signbit is set (less than zero).
<code>copysign(x1, x2, /[, out, where, casting, ...])</code>	Change the sign of x1 to that of x2, element-wise.
<code>frexp(x[, out1, out2], / [[, out, where, ...])</code>	Decompose the elements of x into mantissa and twos exponent.
<code>ldexp(x1, x2, /[, out, where, casting, ...])</code>	Returns $x1 * 2^{x2}$, element-wise.
<code>nextafter(x1, x2, /[, out, where, casting, ...])</code>	Return the next floating-point value after x1 towards x2, element-wise.
<code>spacing(x, /[, out, where, casting, order, ...])</code>	Return the distance between x and the nearest adjacent number.

`numpy.signbit(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'signbit'>`

Returns element-wise True where signbit is set (less than zero).

Parameters

- x**
[array_like] The input value(s).
- out**
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is

stored. If provided, it must have a shape that the inputs broadcast to. If not provided or `None`, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is `True`, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**result**

[ndarray of bool] Output array, or reference to `out` if that was supplied. This is a scalar if `x` is a scalar.

See also:

[sign](#)
[copysign](#)

Examples

```
>>> import numpy as np
>>> np.signbit(-1.2)
True
>>> np.signbit(np.array([1, -2.3, 2.1]))
array([False,  True,  False])
```

`numpy.copysign(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'copysign'>`

Change the sign of `x1` to that of `x2`, element-wise.

If `x2` is a scalar, its sign will be copied to all elements of `x1`.

Parameters**x1**

[array_like] Values to change the sign of.

x2

[array_like] The sign of `x2` is copied to `x1`. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or `None`, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is `True`, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**out**

[ndarray or scalar] The values of *x1* with the sign of *x2*. This is a scalar if both *x1* and *x2* are scalars.

See also:

[sign](#)

[signbit](#)

Examples

```
>>> import numpy as np
>>> np.copysign(1.3, -1)
-1.3
>>> 1/np.copysign(0, 1)
inf
>>> 1/np.copysign(0, -1)
-inf
```

```
>>> np.copysign([-1, 0, 1], -1.1)
array([-1., -0., -1.])
>>> np.copysign([-1, 0, 1], np.arange(3)-1)
array([-1., 0., 1.])
```

`numpy.frexpx(x, [out1, out2, ], [out=(None, None), ], *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'frexp'>`

Decompose the elements of *x* into mantissa and twos exponent.

Returns (*mantissa*, *exponent*), where $x = \text{mantissa} * 2^{**\text{exponent}}$. The mantissa lies in the open interval(-1, 1), while the twos exponent is a signed integer.

Parameters**x**

[array_like] Array of numbers to be decomposed.

out1

[ndarray, optional] Output array for the mantissa. Must have the same shape as *x*.

out2

[ndarray, optional] Output array for the exponent. Must have the same shape as *x*.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

mantissa

[ndarray] Floating values between -1 and 1. This is a scalar if x is a scalar.

exponent

[ndarray] Integer exponents of 2. This is a scalar if x is a scalar.

See also:

[ldexp](#)

Compute $y = x1 * 2^{**x2}$, the inverse of [frexp](#).

Notes

Complex dtypes are not supported, they will raise a `TypeError`.

Examples

```
>>> import numpy as np
>>> x = np.arange(9)
>>> y1, y2 = np.frexp(x)
>>> y1
array([ 0.   ,  0.5   ,  0.5   ,  0.75  ,  0.5   ,  0.625 ,  0.75  ,  0.875 ,
        0.5   ])
>>> y2
array([0, 1, 2, 2, 3, 3, 3, 3, 4], dtype=int32)
>>> y1 * 2**y2
array([ 0.,  1.,  2.,  3.,  4.,  5.,  6.,  7.,  8.]
```

```
numpy.ldexp(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'ldexp'>
```

Returns $x1 * 2^{**x2}$, element-wise.

The mantissas $x1$ and twos exponents $x2$ are used to construct floating point numbers $x1 * 2^{**x2}$.

Parameters

x1

[array_like] Array of multipliers.

x2

[array_like, int] Array of twos exponents. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or `None`, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is `True`, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain

its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is *False* will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray or scalar] The result of $x1 * 2^{**}x2$. This is a scalar if both *x1* and *x2* are scalars.

See also:

frexp

Return (y1, y2) from $x = y1 * 2^{**}y2$, inverse to *ldexp*.

Notes

Complex dtypes are not supported, they will raise a *TypeError*.

ldexp is useful as the inverse of *frexp*, if used by itself it is more clear to simply use the expression $x1 * 2^{**}x2$.

Examples

```
>>> import numpy as np
>>> np.ldexp(5, np.arange(4))
array([ 5., 10., 20., 40.], dtype=float16)
```

```
>>> x = np.arange(6)
>>> np.ldexp(*np.frexp(x))
array([ 0., 1., 2., 3., 4., 5.] )
```

`numpy.nextafter(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'nextafter'>`

Return the next floating-point value after *x1* towards *x2*, element-wise.

Parameters

x1

[array_like] Values to find the next representable value of.

x2

[array_like] The direction where to look for the next representable value of *x1*. If *x1.shape* != *x2.shape*, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or *None*, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is *True*, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain

its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**out**

[ndarray or scalar] The next representable values of *x1* in the direction of *x2*. This is a scalar if both *x1* and *x2* are scalars.

Examples

```
>>> import numpy as np
>>> eps = np.finfo(np.float64).eps
>>> np.nextafter(1, 2) == eps + 1
True
>>> np.nextafter([1, 2], [2, 1]) == [eps + 1, 2 - eps]
array([ True,  True])
```

`numpy.spacing(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'spacing'>`

Return the distance between *x* and the nearest adjacent number.

Parameters**x**

[array_like] Values to find the spacing of.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or `None`, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is `True`, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**out**

[ndarray or scalar] The spacing of values of *x*. This is a scalar if *x* is a scalar.

Notes

It can be considered as a generalization of EPS: `spacing(np.float64(1)) == np.finfo(np.float64).eps`, and there should not be any representable number between `x + spacing(x)` and `x` for any finite `x`.

Spacing of `+/- inf` and `NaN` is `NaN`.

Examples

```
>>> import numpy as np
>>> np.spacing(1) == np.finfo(np.float64).eps
True
```

Rational routines

<code>lcm(x1, x2, /[, out, where, casting, order, ...])</code>	Returns the lowest common multiple of <code> x1 </code> and <code> x2 </code>
<code>gcd(x1, x2, /[, out, where, casting, order, ...])</code>	Returns the greatest common divisor of <code> x1 </code> and <code> x2 </code>

```
numpy.lcm(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'lcm'>
```

Returns the lowest common multiple of `|x1|` and `|x2|`

Parameters

`x1, x2`

[array_like, int] Arrays of values. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

Returns

`y`

[ndarray or scalar] The lowest common multiple of the absolute value of the inputs This is a scalar if both `x1` and `x2` are scalars.

See also:

`gcd`

The greatest common divisor

Examples

```
>>> import numpy as np
>>> np.lcm(12, 20)
60
>>> np.lcm.reduce([3, 12, 20])
60
>>> np.lcm.reduce([40, 12, 20])
120
>>> np.lcm(np.arange(6), 20)
array([ 0, 20, 20, 60, 20, 20])
```

```
numpy.gcd(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'gcd'>
```

Returns the greatest common divisor of $|x1|$ and $|x2|$

Parameters

x1, x2

[array_like, int] Arrays of values. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

Returns

y

[ndarray or scalar] The greatest common divisor of the absolute value of the inputs This is a scalar if both `x1` and `x2` are scalars.

See also:

[*lcm*](#)

The lowest common multiple

Examples

```
>>> import numpy as np
>>> np.gcd(12, 20)
4
>>> np.gcd.reduce([15, 25, 35])
5
>>> np.gcd(np.arange(6), 20)
array([20,  1,  2,  1,  4,  5])
```

Arithmetic operations

<code>add(x1, x2, /[, out, where, casting, order, ...])</code>	Add arguments element-wise.
<code>reciprocal(x, /[, out, where, casting, ...])</code>	Return the reciprocal of the argument, element-wise.
<code>positive(x, /[, out, where, casting, order, ...])</code>	Numerical positive, element-wise.
<code>negative(x, /[, out, where, casting, order, ...])</code>	Numerical negation, element-wise.
<code>multiply(x1, x2, /[, out, where, casting, ...])</code>	Multiply arguments element-wise.
<code>divide(x1, x2, /[, out, where, casting, ...])</code>	Divide arguments element-wise.
<code>power(x1, x2, /[, out, where, casting, ...])</code>	First array elements raised to powers from second array, element-wise.
<code>pow(x1, x2, /[, out, where, casting, order, ...])</code>	First array elements raised to powers from second array, element-wise.
<code>subtract(x1, x2, /[, out, where, casting, ...])</code>	Subtract arguments, element-wise.
<code>true_divide(x1, x2, /[, out, where, ...])</code>	Divide arguments element-wise.
<code>floor_divide(x1, x2, /[, out, where, ...])</code>	Return the largest integer smaller or equal to the division of the inputs.
<code>float_power(x1, x2, /[, out, where, ...])</code>	First array elements raised to powers from second array, element-wise.
<code>fmod(x1, x2, /[, out, where, casting, ...])</code>	Returns the element-wise remainder of division.
<code>mod(x1, x2, /[, out, where, casting, order, ...])</code>	Returns the element-wise remainder of division.
<code>modf(x[, out1, out2], / [[, out, where, ...])</code>	Return the fractional and integral parts of an array, element-wise.
<code>remainder(x1, x2, /[, out, where, casting, ...])</code>	Returns the element-wise remainder of division.
<code>divmod(x1, x2[, out1, out2], / [[, out, ...])</code>	Return element-wise quotient and remainder simultaneously.

`numpy.add(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'add'>`

Add arguments element-wise.

Parameters

x1, x2

[array_like] The arrays to be added. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

add

[ndarray or scalar] The sum of `x1` and `x2`, element-wise. This is a scalar if both `x1` and `x2` are scalars.

Notes

Equivalent to $x1 + x2$ in terms of array broadcasting.

Examples

```
>>> import numpy as np
>>> np.add(1.0, 4.0)
5.0
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> np.add(x1, x2)
array([[ 0.,  2.,  4.],
       [ 3.,  5.,  7.],
       [ 6.,  8., 10.]])
```

The `+` operator can be used as a shorthand for `np.add` on ndarrays.

```
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> x1 + x2
array([[ 0.,  2.,  4.],
       [ 3.,  5.,  7.],
       [ 6.,  8., 10.]])
```

`numpy.reciprocal(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'reciprocal'>`

Return the reciprocal of the argument, element-wise.

Calculates $1/x$.

Parameters

x

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] Return array. This is a scalar if *x* is a scalar.

Notes

Note: This function is not designed to work with integers.

For integer arguments with absolute value larger than 1 the result is always zero because of the way Python handles integer division. For integer zero the result is an overflow.

Examples

```
>>> import numpy as np
>>> np.reciprocal(2.)
0.5
>>> np.reciprocal([1, 2., 3.33])
array([ 1.          ,  0.5          ,  0.3003003])
```

`numpy.positive(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'positive'>`

Numerical positive, element-wise.

Parameters

x
[array_like or scalar] Input array.

Returns

y
[ndarray or scalar] Returned array or scalar: $y = +x$. This is a scalar if x is a scalar.

Notes

Equivalent to `x.copy()`, but only defined for types that support arithmetic.

Examples

```
>>> import numpy as np
```

```
>>> x1 = np.array([[1., -1.]])
>>> np.positive(x1)
array([ 1., -1.]
```

The unary `+` operator can be used as a shorthand for `np.positive` on ndarrays.

```
>>> x1 = np.array([[1., -1.]])
>>> +x1
array([ 1., -1.]
```

`numpy.negative(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'negative'>`

Numerical negation, element-wise.

Parameters

x

[array_like or scalar] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray or scalar] Returned array or scalar: $y = -x$. This is a scalar if *x* is a scalar.

Examples

```
>>> import numpy as np
>>> np.negative([1., -1.])
array([-1.,  1.])
```

The unary `-` operator can be used as a shorthand for `np.negative` on ndarrays.

```
>>> x1 = np.array([1., -1.])
>>> -x1
array([-1.,  1.])
```

```
numpy.multiply(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'multiply'>
```

Multiply arguments element-wise.

Parameters

x1, x2

[array_like] Input arrays to be multiplied. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**y**

[ndarray] The product of $x1$ and $x2$, element-wise. This is a scalar if both $x1$ and $x2$ are scalars.

Notes

Equivalent to $x1 * x2$ in terms of array broadcasting.

Examples

```
>>> import numpy as np
>>> np.multiply(2.0, 4.0)
8.0
```

```
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> np.multiply(x1, x2)
array([[ 0.,  1.,  4.],
       [ 0.,  4., 10.],
       [ 0.,  7., 16.]])
```

The `*` operator can be used as a shorthand for `np.multiply` on ndarrays.

```
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> x1 * x2
array([[ 0.,  1.,  4.],
       [ 0.,  4., 10.],
       [ 0.,  7., 16.]])
```

`numpy.divide(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'divide'>`

Divide arguments element-wise.

Parameters**x1**

[array_like] Dividend array.

x2

[array_like] Divisor array. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain

its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray or scalar] The quotient $x1/x2$, element-wise. This is a scalar if both *x1* and *x2* are scalars.

See also:***seterr***

Set whether to raise or warn on overflow, underflow and division by zero.

Notes

Equivalent to $x1 / x2$ in terms of array-broadcasting.

The `true_divide(x1, x2)` function is an alias for `divide(x1, x2)`.

Examples

```
>>> import numpy as np
>>> np.divide(2.0, 4.0)
0.5
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> np.divide(x1, x2)
array([[nan, 1. , 1. ],
       [inf, 4. , 2.5],
       [inf, 7. , 4. ]])
```

The `/` operator can be used as a shorthand for `np.divide` on ndarrays.

```
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = 2 * np.ones(3)
>>> x1 / x2
array([[0. , 0.5, 1. ],
       [1.5, 2. , 2.5],
       [3. , 3.5, 4. ]])
```

`numpy.power(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'power'>`

First array elements raised to powers from second array, element-wise.

Raise each base in *x1* to the positionally-corresponding power in *x2*. *x1* and *x2* must be broadcastable to the same shape.

An integer type raised to a negative integer power will raise a `ValueError`.

Negative values raised to a non-integral value will return `nan`. To get complex results, cast the input to complex, or specify the `dtype` to be `complex` (see the example below).

Parameters

x1

[array_like] The bases.

x2[array_like] The exponents. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).**out**

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.****kwargs**For other keyword-only arguments, see the *ufunc docs*.**Returns****y**[ndarray] The bases in *x1* raised to the exponents in *x2*. This is a scalar if both *x1* and *x2* are scalars.**See also:***float_power*

power function that promotes integers to float

Examples

```
>>> import numpy as np
```

Cube each element in an array.

```
>>> x1 = np.arange(6)
>>> x1
[0, 1, 2, 3, 4, 5]
>>> np.power(x1, 3)
array([ 0,  1,  8, 27, 64, 125])
```

Raise the bases to different exponents.

```
>>> x2 = [1.0, 2.0, 3.0, 3.0, 2.0, 1.0]
>>> np.power(x1, x2)
array([ 0.,  1.,  8., 27., 16.,  5.]
```

The effect of broadcasting.

```
>>> x2 = np.array([[1, 2, 3, 3, 2, 1], [1, 2, 3, 3, 2, 1]])
>>> x2
array([[1, 2, 3, 3, 2, 1],
       [1, 2, 3, 3, 2, 1]])
```

(continues on next page)

(continued from previous page)

```
>>> np.power(x1, x2)
array([[ 0,  1,  8, 27, 16,  5],
       [ 0,  1,  8, 27, 16,  5]])
```

The `**` operator can be used as a shorthand for `np.power` on ndarrays.

```
>>> x2 = np.array([1, 2, 3, 3, 2, 1])
>>> x1 = np.arange(6)
>>> x1 ** x2
array([ 0,  1,  8, 27, 16,  5])
```

Negative values raised to a non-integral value will result in `nan` (and a warning will be generated).

```
>>> x3 = np.array([-1.0, -4.0])
>>> with np.errstate(invalid='ignore'):
...     p = np.power(x3, 1.5)
...
>>> p
array([nan, nan])
```

To get complex results, give the argument `dtype=np.complex128`.

```
>>> np.power(x3, 1.5, dtype=np.complex128)
array([-1.83697020e-16-1.j, -1.46957616e-15-8.j])
```

`numpy.pow(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'power'>`

First array elements raised to powers from second array, element-wise.

Raise each base in `x1` to the positionally-corresponding power in `x2`. `x1` and `x2` must be broadcastable to the same shape.

An integer type raised to a negative integer power will raise a `ValueError`.

Negative values raised to a non-integral value will return `nan`. To get complex results, cast the input to complex, or specify the `dtype` to be `complex` (see the example below).

Parameters

x1

[array_like] The bases.

x2

[array_like] The exponents. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or `None`, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is `True`, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**For other keyword-only arguments, see the [ufunc docs](#).**Returns****y**[ndarray] The bases in *x1* raised to the exponents in *x2*. This is a scalar if both *x1* and *x2* are scalars.**See also:**[*float_power*](#)

power function that promotes integers to float

Examples

```
>>> import numpy as np
```

Cube each element in an array.

```
>>> x1 = np.arange(6)
>>> x1
[0, 1, 2, 3, 4, 5]
>>> np.power(x1, 3)
array([ 0,  1,  8, 27, 64, 125])
```

Raise the bases to different exponents.

```
>>> x2 = [1.0, 2.0, 3.0, 3.0, 2.0, 1.0]
>>> np.power(x1, x2)
array([ 0.,  1.,  8., 27., 16.,  5.])
```

The effect of broadcasting.

```
>>> x2 = np.array([[1, 2, 3, 3, 2, 1], [1, 2, 3, 3, 2, 1]])
>>> x2
array([[1, 2, 3, 3, 2, 1],
       [1, 2, 3, 3, 2, 1]])
>>> np.power(x1, x2)
array([[ 0,  1,  8, 27, 16,  5],
       [ 0,  1,  8, 27, 16,  5]])
```

The ****** operator can be used as a shorthand for `np.power` on ndarrays.

```
>>> x2 = np.array([1, 2, 3, 3, 2, 1])
>>> x1 = np.arange(6)
>>> x1 ** x2
array([ 0,  1,  8, 27, 16,  5])
```

Negative values raised to a non-integral value will result in `nan` (and a warning will be generated).

```
>>> x3 = np.array([-1.0, -4.0])
>>> with np.errstate(invalid='ignore'):
...     p = np.power(x3, 1.5)
...
>>> p
array([nan, nan])
```

To get complex results, give the argument `dtype=np.complex128`.

```
>>> np.power(x3, 1.5, dtype=np.complex128)
array([-1.83697020e-16-1.j, -1.46957616e-15-8.j])
```

`numpy.subtract(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'subtract'>`

Subtract arguments, element-wise.

Parameters

x1, x2

[array_like] The arrays to be subtracted from each other. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] The difference of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

Notes

Equivalent to `x1 - x2` in terms of array broadcasting.

Examples

```
>>> import numpy as np
>>> np.subtract(1.0, 4.0)
-3.0
```

```
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> np.subtract(x1, x2)
array([[ 0.,  0.,  0.],
       [ 3.,  3.,  3.],
       [ 6.,  6.,  6.]])
```

The `-` operator can be used as a shorthand for `np.subtract` on ndarrays.

```
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> x1 - x2
array([[0., 0., 0.],
       [3., 3., 3.],
       [6., 6., 6.]])
```

`numpy.true_divide(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'divide'>`

Divide arguments element-wise.

Parameters

x1

[array_like] Dividend array.

x2

[array_like] Divisor array. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray or scalar] The quotient `x1/x2`, element-wise. This is a scalar if both *x1* and *x2* are scalars.

See also:

[seterr](#)

Set whether to raise or warn on overflow, underflow and division by zero.

Notes

Equivalent to `x1 / x2` in terms of array-broadcasting.

The `true_divide(x1, x2)` function is an alias for `divide(x1, x2)`.

Examples

```
>>> import numpy as np
>>> np.divide(2.0, 4.0)
0.5
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = np.arange(3.0)
>>> np.divide(x1, x2)
array([[nan, 1. , 1. ],
       [inf, 4. , 2.5],
       [inf, 7. , 4. ]])
```

The `/` operator can be used as a shorthand for `np.divide` on ndarrays.

```
>>> x1 = np.arange(9.0).reshape((3, 3))
>>> x2 = 2 * np.ones(3)
>>> x1 / x2
array([[0. , 0.5, 1. ],
       [1.5, 2. , 2.5],
       [3. , 3.5, 4. ]])
```

`numpy.floor_divide(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'floor_divide'>`

Return the largest integer smaller or equal to the division of the inputs. It is equivalent to the Python `//` operator and pairs with the Python `%` (*remainder*), function so that `a = a % b + b * (a // b)` up to roundoff.

Parameters

x1

[array_like] Numerator.

x2

[array_like] Denominator. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

y

[ndarray] `y = floor(x1/x2)` This is a scalar if both *x1* and *x2* are scalars.

See also:

remainder

Remainder complementary to `floor_divide`.

divmod

Simultaneous floor division and remainder.

divide

Standard division.

floor

Round a number to the nearest integer toward minus infinity.

ceil

Round a number to the nearest integer toward infinity.

Examples

```
>>> import numpy as np
>>> np.floor_divide(7,3)
2
>>> np.floor_divide([1., 2., 3., 4.], 2.5)
array([ 0.,  0.,  1.,  1.]
```

The `//` operator can be used as a shorthand for `np.floor_divide` on ndarrays.

```
>>> x1 = np.array([1., 2., 3., 4.])
>>> x1 // 2.5
array([0., 0., 1., 1.]
```

`numpy.float_power(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'float_power'>`

First array elements raised to powers from second array, element-wise.

Raise each base in *x1* to the positionally-corresponding power in *x2*. *x1* and *x2* must be broadcastable to the same shape. This differs from the power function in that integers, float16, and float32 are promoted to floats with a minimum precision of float64 so that the result is always inexact. The intent is that the function will return a usable result for negative powers and seldom overflow for positive powers.

Negative values raised to a non-integral value will return `nan`. To get complex results, cast the input to complex, or specify the `dtype` to be `complex` (see the example below).

Parameters***x1***

[array_like] The bases.

x2

[array_like] The exponents. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] The bases in *x1* raised to the exponents in *x2*. This is a scalar if both *x1* and *x2* are scalars.

See also:

[*power*](#)

power function that preserves type

Examples

```
>>> import numpy as np
```

Cube each element in a list.

```
>>> x1 = range(6)
>>> x1
[0, 1, 2, 3, 4, 5]
>>> np.float_power(x1, 3)
array([ 0.,  1.,  8., 27., 64., 125.])
```

Raise the bases to different exponents.

```
>>> x2 = [1.0, 2.0, 3.0, 3.0, 2.0, 1.0]
>>> np.float_power(x1, x2)
array([ 0.,  1.,  8., 27., 16.,  5.])
```

The effect of broadcasting.

```
>>> x2 = np.array([[1, 2, 3, 3, 2, 1], [1, 2, 3, 3, 2, 1]])
>>> x2
array([[1, 2, 3, 3, 2, 1],
       [1, 2, 3, 3, 2, 1]])
>>> np.float_power(x1, x2)
array([[ 0.,  1.,  8., 27., 16.,  5.],
       [ 0.,  1.,  8., 27., 16.,  5.]])
```

Negative values raised to a non-integral value will result in nan (and a warning will be generated).

```
>>> x3 = np.array([-1, -4])
>>> with np.errstate(invalid='ignore'):
...     p = np.float_power(x3, 1.5)
...
>>> p
array([nan, nan])
```

To get complex results, give the argument `dtype=np.complex128`.

```
>>> np.float_power(x3, 1.5, dtype=np.complex128)
array([-1.83697020e-16-1.j, -1.46957616e-15-8.j])
```

```
numpy.fmod(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'fmod'>
```

Returns the element-wise remainder of division.

This is the NumPy implementation of the C library function `fmod`, the remainder has the same sign as the dividend `x1`. It is equivalent to the Matlab(TM) `rem` function and should not be confused with the Python modulus operator `x1 % x2`.

Parameters

x1

[array_like] Dividend.

x2

[array_like] Divisor. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or `None`, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is `True`, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[array_like] The remainder of the division of `x1` by `x2`. This is a scalar if both `x1` and `x2` are scalars.

See also:

[remainder](#)

Equivalent to the Python `%` operator.

[divide](#)

Notes

The result of the modulo operation for negative dividend and divisors is bound by conventions. For [fmod](#), the sign of result is the sign of the dividend, while for [remainder](#) the sign of the result is the sign of the divisor. The [fmod](#) function is equivalent to the Matlab(TM) `rem` function.

Examples

```
>>> import numpy as np
>>> np.fmod([-3, -2, -1, 1, 2, 3], 2)
array([-1,  0, -1,  1,  0,  1])
>>> np.remainder([-3, -2, -1, 1, 2, 3], 2)
array([1, 0, 1, 1, 0, 1])
```

```
>>> np.fmod([5, 3], [2, 2.])
array([ 1.,  1.])
>>> a = np.arange(-3, 3).reshape(3, 2)
>>> a
array([[ -3, -2],
       [ -1,  0],
       [  1,  2]])
>>> np.fmod(a, [2, 2])
array([[ -1,  0],
       [ -1,  0],
       [  1,  0]])
```

`numpy.mod(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'remainder'>`

Returns the element-wise remainder of division.

Computes the remainder complementary to the `floor_divide` function. It is equivalent to the Python modulus operator `x1 % x2` and has the same sign as the divisor `x2`. The MATLAB function equivalent to `np.remainder` is `mod`.

Warning: This should not be confused with:

- Python's `math.remainder` and C's `remainder`, which compute the IEEE remainder, which are the complement to `round(x1 / x2)`.
- The MATLAB `rem` function and or the C `%` operator which is the complement to `int(x1 / x2)`.

Parameters

x1

[array_like] Dividend array.

x2

[array_like] Divisor array. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the `out` array will be set to the ufunc result. Elsewhere, the `out` array will retain its original value. Note that if an uninitialized `out` array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] The element-wise remainder of the quotient `floor_divide(x1, x2)`. This is a scalar if both *x1* and *x2* are scalars.

See also:

[*floor_divide*](#)

Equivalent of Python `//` operator.

[*divmod*](#)

Simultaneous floor division and remainder.

[*fmod*](#)

Equivalent of the MATLAB `rem` function.

[*divide, floor*](#)

Notes

Returns 0 when *x2* is 0 and both *x1* and *x2* are (arrays of) integers. `mod` is an alias of `remainder`.

Examples

```
>>> import numpy as np
>>> np.remainder([4, 7], [2, 3])
array([0, 1])
>>> np.remainder(np.arange(7), 5)
array([0, 1, 2, 3, 4, 0, 1])
```

The `%` operator can be used as a shorthand for `np.remainder` on ndarrays.

```
>>> x1 = np.arange(7)
>>> x1 % 5
array([0, 1, 2, 3, 4, 0, 1])
```

`numpy.modf(x, [out1, out2, ], [out=(None, None), ], *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'modf'>`

Return the fractional and integral parts of an array, element-wise.

The fractional and integral parts are negative if the given number is negative.

Parameters

x

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**y1**

[ndarray] Fractional part of *x*. This is a scalar if *x* is a scalar.

y2

[ndarray] Integral part of *x*. This is a scalar if *x* is a scalar.

See also:**[divmod](#)**

`divmod(x, 1)` is equivalent to `modf` with the return values switched, except it always has a positive remainder.

Notes

For integer input the return values are floats.

Examples

```
>>> import numpy as np
>>> np.modf([0, 3.5])
(array([ 0. ,  0.5]), array([ 0.,  3.]))
>>> np.modf(-0.5)
(-0.5, -0)
```

`numpy.remainder(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'remainder'>`

Returns the element-wise remainder of division.

Computes the remainder complementary to the [floor_divide](#) function. It is equivalent to the Python modulus operator `x1 % x2` and has the same sign as the divisor *x2*. The MATLAB function equivalent to `np.remainder` is `mod`.

Warning: This should not be confused with:

- Python's `math.remainder` and C's `remainder`, which compute the IEEE remainder, which are the complement to `round(x1 / x2)`.
- The MATLAB `rem` function and or the C `%` operator which is the complement to `int(x1 / x2)`.

Parameters**x1**

[array_like] Dividend array.

x2

[array_like] Divisor array. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**y**

[ndarray] The element-wise remainder of the quotient `floor_divide(x1, x2)`. This is a scalar if both *x1* and *x2* are scalars.

See also:[*floor_divide*](#)

Equivalent of Python `//` operator.

[*divmod*](#)

Simultaneous floor division and remainder.

[*fmod*](#)

Equivalent of the MATLAB `rem` function.

[*divide, floor*](#)**Notes**

Returns 0 when *x2* is 0 and both *x1* and *x2* are (arrays of) integers. `mod` is an alias of `remainder`.

Examples

```
>>> import numpy as np
>>> np.remainder([4, 7], [2, 3])
array([0, 1])
>>> np.remainder(np.arange(7), 5)
array([0, 1, 2, 3, 4, 0, 1])
```

The `%` operator can be used as a shorthand for `np.remainder` on ndarrays.

```
>>> x1 = np.arange(7)
>>> x1 % 5
array([0, 1, 2, 3, 4, 0, 1])
```

```
numpy.divmod(x1, x2, [out1, out2, ], [out=(None, None), ], *, where=True, casting='same_kind', order='K',  
             dtype=None, subok=True[, signature]) = <ufunc 'divmod'>
```

Return element-wise quotient and remainder simultaneously.

`np.divmod(x, y)` is equivalent to `(x // y, x % y)`, but faster because it avoids redundant work. It is used to implement the Python built-in function `divmod` on NumPy arrays.

Parameters

x1

[array_like] Dividend array.

x2

[array_like] Divisor array. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out1

[ndarray] Element-wise quotient resulting from floor division. This is a scalar if both *x1* and *x2* are scalars.

out2

[ndarray] Element-wise remainder from floor division. This is a scalar if both *x1* and *x2* are scalars.

See also:

[*floor_divide*](#)

Equivalent to Python's `//` operator.

[*remainder*](#)

Equivalent to Python's `%` operator.

[*modf*](#)

Equivalent to `divmod(x, 1)` for positive *x* with the return values switched.

Examples

```
>>> import numpy as np
>>> np.divmod(np.arange(5), 3)
(array([0, 0, 0, 1, 1]), array([0, 1, 2, 0, 1]))
```

The `divmod` function can be used as a shorthand for `np.divmod` on ndarrays.

```
>>> x = np.arange(5)
>>> divmod(x, 3)
(array([0, 0, 0, 1, 1]), array([0, 1, 2, 0, 1]))
```

Handling complex numbers

<code>angle(z[, deg])</code>	Return the angle of the complex argument.
<code>real(val)</code>	Return the real part of the complex argument.
<code>imag(val)</code>	Return the imaginary part of the complex argument.
<code>conj(x, /[, out, where, casting, order, ...])</code>	Return the complex conjugate, element-wise.
<code>conjugate(x, /[, out, where, casting, ...])</code>	Return the complex conjugate, element-wise.

`numpy.angle(z, deg=False)`

Return the angle of the complex argument.

Parameters

z
[array_like] A complex number or sequence of complex numbers.

deg
[bool, optional] Return angle in degrees if True, radians if False (default).

Returns

angle
[ndarray or scalar] The counterclockwise angle from the positive real axis on the complex plane in the range $(-\pi, \pi]$, with dtype as `numpy.float64`.

See also:

[`arctan2`](#)
[`absolute`](#)

Notes

This function passes the imaginary and real parts of the argument to [`arctan2`](#) to compute the result; consequently, it follows the convention of [`arctan2`](#) when the magnitude of the argument is zero. See example.

Examples

```
>>> import numpy as np
>>> np.angle([1.0, 1.0j, 1+1j])           # in radians
array([ 0.          ,  1.57079633,  0.78539816]) # may vary
>>> np.angle(1+1j, deg=True)              # in degrees
45.0
>>> np.angle([0., -0., complex(0., -0.), complex(-0., -0.)]) # convention
array([ 0.          ,  3.14159265, -0.          , -3.14159265])
```

`numpy.real(val)`

Return the real part of the complex argument.

Parameters

val

[array_like] Input array.

Returns

out

[ndarray or scalar] The real component of the complex argument. If *val* is real, the type of *val* is used for the output. If *val* has complex elements, the returned type is float.

See also:

[*real_if_close*](#), [*imag*](#), [*angle*](#)

Examples

```
>>> import numpy as np
>>> a = np.array([1+2j, 3+4j, 5+6j])
>>> a.real
array([1.,  3.,  5.])
>>> a.real = 9
>>> a
array([9.+2.j,  9.+4.j,  9.+6.j])
>>> a.real = np.array([9, 8, 7])
>>> a
array([9.+2.j,  8.+4.j,  7.+6.j])
>>> np.real(1 + 1j)
1.0
```

`numpy.imag(val)`

Return the imaginary part of the complex argument.

Parameters

val

[array_like] Input array.

Returns

out

[ndarray or scalar] The imaginary component of the complex argument. If *val* is real, the type of *val* is used for the output. If *val* has complex elements, the returned type is float.

See also:

real, angle, real_if_close

Examples

```

>>> import numpy as np
>>> a = np.array([1+2j, 3+4j, 5+6j])
>>> a.imag
array([2., 4., 6.])
>>> a.imag = np.array([8, 10, 12])
>>> a
array([1. +8.j, 3.+10.j, 5.+12.j])
>>> np.imag(1 + 1j)
1.0

```

`numpy.conj(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])`
 = `<ufunc 'conjugate'>`

Return the complex conjugate, element-wise.

The complex conjugate of a complex number is obtained by changing the sign of its imaginary part.

Parameters

x

[array_like] Input value.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

y

[ndarray] The complex conjugate of *x*, with same dtype as *y*. This is a scalar if *x* is a scalar.

Notes

conj is an alias for *conjugate*:

```

>>> np.conj is np.conjugate
True

```

Examples

```
>>> import numpy as np
>>> np.conjugate(1+2j)
(1-2j)
```

```
>>> x = np.eye(2) + 1j * np.eye(2)
>>> np.conjugate(x)
array([[ 1.-1.j,  0.-0.j],
       [ 0.-0.j,  1.-1.j]])
```

`numpy.conjugate(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'conjugate'>`

Return the complex conjugate, element-wise.

The complex conjugate of a complex number is obtained by changing the sign of its imaginary part.

Parameters

x

[array_like] Input value.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] The complex conjugate of *x*, with same dtype as *y*. This is a scalar if *x* is a scalar.

Notes

`conj` is an alias for `conjugate`:

```
>>> np.conj is np.conjugate
True
```

Examples

```
>>> import numpy as np
>>> np.conjugate(1+2j)
(1-2j)
```

```
>>> x = np.eye(2) + 1j * np.eye(2)
>>> np.conjugate(x)
array([[ 1.-1.j,   0.-0.j],
       [ 0.-0.j,   1.-1.j]])
```

Extrema finding

<i>maximum</i> (x1, x2, /[, out, where, casting, ...])	Element-wise maximum of array elements.
<i>max</i> (a[, axis, out, keepdims, initial, where])	Return the maximum of an array or maximum along an axis.
<i>amax</i> (a[, axis, out, keepdims, initial, where])	Return the maximum of an array or maximum along an axis.
<i>fmax</i> (x1, x2, /[, out, where, casting, ...])	Element-wise maximum of array elements.
<i>nanmax</i> (a[, axis, out, keepdims, initial, where])	Return the maximum of an array or maximum along an axis, ignoring any NaNs.
<i>minimum</i> (x1, x2, /[, out, where, casting, ...])	Element-wise minimum of array elements.
<i>min</i> (a[, axis, out, keepdims, initial, where])	Return the minimum of an array or minimum along an axis.
<i>amin</i> (a[, axis, out, keepdims, initial, where])	Return the minimum of an array or minimum along an axis.
<i>fmin</i> (x1, x2, /[, out, where, casting, ...])	Element-wise minimum of array elements.
<i>nanmin</i> (a[, axis, out, keepdims, initial, where])	Return minimum of an array or minimum along an axis, ignoring any NaNs.

`numpy.maximum(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'maximum'>`

Element-wise maximum of array elements.

Compare two arrays and return a new array containing the element-wise maxima. If one of the elements being compared is a NaN, then that element is returned. If both elements are NaNs then the first is returned. The latter distinction is important for complex NaNs, which are defined as at least one of the real or imaginary parts being a NaN. The net effect is that NaNs are propagated.

Parameters

x1, x2

[array_like] The arrays holding the elements to be compared. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain

its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is `False` will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray or scalar] The maximum of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

See also:***minimum***

Element-wise minimum of two arrays, propagates NaNs.

fmax

Element-wise maximum of two arrays, ignores NaNs.

amax

The maximum value of an array along a given axis, propagates NaNs.

nanmax

The maximum value of an array along a given axis, ignores NaNs.

fmin*, *amin*, *nanmin**Notes**

The maximum is equivalent to `np.where(x1 >= x2, x1, x2)` when neither *x1* nor *x2* are nans, but it is faster and does proper broadcasting.

Examples

```
>>> import numpy as np
>>> np.maximum([2, 3, 4], [1, 5, 2])
array([2, 5, 4])
```

```
>>> np.maximum(np.eye(2), [0.5, 2]) # broadcasting
array([[ 1. ,  2. ],
       [ 0.5,  2. ]])
```

```
>>> np.maximum([np.nan, 0, np.nan], [0, np.nan, np.nan])
array([nan, nan, nan])
>>> np.maximum(np.inf, 1)
inf
```

`numpy.max(a, axis=None, out=None, keepdims=<no value>, initial=<no value>, where=<no value>)`

Return the maximum of an array or maximum along an axis.

Parameters

a

[array_like] Input data.

axis

[None or int or tuple of ints, optional] Axis or axes along which to operate. By default, flattened input is used. If this is a tuple of ints, the maximum is selected over multiple axes, instead of a single axis or all the axes as before.

out

[ndarray, optional] Alternative output array in which to place the result. Must be of the same shape and buffer length as the expected output. See `ufuncs-output-type` for more details.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.

If the default value is passed, then *keepdims* will not be passed through to the `max` method of sub-classes of `ndarray`, however any non-default value will be. If the sub-class' method does not implement *keepdims* any exceptions will be raised.

initial

[scalar, optional] The minimum value of an output element. Must be present to allow computation on empty slice. See `reduce` for details.

where

[array_like of bool, optional] Elements to compare for the maximum. See `reduce` for details.

Returns**max**

[ndarray or scalar] Maximum of *a*. If *axis* is None, the result is a scalar value. If *axis* is an int, the result is an array of dimension `a.ndim - 1`. If *axis* is a tuple, the result is an array of dimension `a.ndim - len(axis)`.

See also:*min*

The minimum value of an array along a given axis, propagating any NaNs.

nanmax

The maximum value of an array along a given axis, ignoring any NaNs.

maximum

Element-wise maximum of two arrays, propagating any NaNs.

fmax

Element-wise maximum of two arrays, ignoring any NaNs.

argmax

Return the indices of the maximum values.

nanmin, minimum, fmin

Notes

NaN values are propagated, that is if at least one item is NaN, the corresponding max value will be NaN as well. To ignore NaN values (MATLAB behavior), please use `nanmax`.

Don't use `max` for element-wise comparison of 2 arrays; when `a.shape[0]` is 2, `maximum(a[0], a[1])` is faster than `max(a, axis=0)`.

Examples

```
>>> import numpy as np
>>> a = np.arange(4).reshape((2,2))
>>> a
array([[0, 1],
       [2, 3]])
>>> np.max(a)           # Maximum of the flattened array
3
>>> np.max(a, axis=0)   # Maxima along the first axis
array([2, 3])
>>> np.max(a, axis=1)   # Maxima along the second axis
array([1, 3])
>>> np.max(a, where=[False, True], initial=-1, axis=0)
array([-1, 3])
>>> b = np.arange(5, dtype=np.float64)
>>> b[2] = np.nan
>>> np.max(b)
np.float64(nan)
>>> np.max(b, where=~np.isnan(b), initial=-1)
4.0
>>> np.nanmax(b)
4.0
```

You can use an initial value to compute the maximum of an empty slice, or to initialize it to a different value:

```
>>> np.max([[ -50], [10]], axis=-1, initial=0)
array([ 0, 10])
```

Notice that the initial value is used as one of the elements for which the maximum is determined, unlike for the default argument Python's `max` function, which is only used for empty iterables.

```
>>> np.max([5], initial=6)
6
>>> max([5], default=6)
5
```

`numpy. amax` (*a*, *axis=None*, *out=None*, *keepdims=<no value>*, *initial=<no value>*, *where=<no value>*)

Return the maximum of an array or maximum along an axis.

`amax` is an alias of `max`.

See also:

`max`

alias of this function

`ndarray.max`

equivalent method

```
numpy.fmax(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[,  
signature]) = <ufunc 'fmax'>
```

Element-wise maximum of array elements.

Compare two arrays and return a new array containing the element-wise maxima. If one of the elements being compared is a NaN, then the non-nan element is returned. If both elements are NaNs then the first is returned. The latter distinction is important for complex NaNs, which are defined as at least one of the real or imaginary parts being a NaN. The net effect is that NaNs are ignored when possible.

Parameters

x1, x2

[array_like] The arrays holding the elements to be compared. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

y

[ndarray or scalar] The maximum of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

See also:

fmin

Element-wise minimum of two arrays, ignores NaNs.

maximum

Element-wise maximum of two arrays, propagates NaNs.

amax

The maximum value of an array along a given axis, propagates NaNs.

nanmax

The maximum value of an array along a given axis, ignores NaNs.

minimum, amin, nanmin

Notes

The `fmax` is equivalent to `np.where(x1 >= x2, x1, x2)` when neither `x1` nor `x2` are NaNs, but it is faster and does proper broadcasting.

Examples

```
>>> import numpy as np
>>> np.fmax([2, 3, 4], [1, 5, 2])
array([ 2,  5,  4])
```

```
>>> np.fmax(np.eye(2), [0.5, 2])
array([[ 1. ,  2. ],
       [ 0.5,  2. ]])
```

```
>>> np.fmax([np.nan, 0, np.nan], [0, np.nan, np.nan])
array([ 0.,  0., nan])
```

`numpy.nanmax(a, axis=None, out=None, keepdims=<no value>, initial=<no value>, where=<no value>)`

Return the maximum of an array or maximum along an axis, ignoring any NaNs. When all-NaN slices are encountered a `RuntimeWarning` is raised and NaN is returned for that slice.

Parameters

a

[array_like] Array containing numbers whose maximum is desired. If *a* is not an array, a conversion is attempted.

axis

[{int, tuple of int, None}, optional] Axis or axes along which the maximum is computed. The default is to compute the maximum of the flattened array.

out

[ndarray, optional] Alternate output array in which to place the result. The default is `None`; if provided, it must have the same shape as the expected output, but the type will be cast if necessary. See [ufuncs-output-type](#) for more details.

keepdims

[bool, optional] If this is set to `True`, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *a*. If the value is anything but the default, then *keepdims* will be passed through to the *max* method of sub-classes of *ndarray*. If the sub-classes methods does not implement *keepdims* any exceptions will be raised.

initial

[scalar, optional] The minimum value of an output element. Must be present to allow computation on empty slice. See [reduce](#) for details.

New in version 1.22.0.

where

[array_like of bool, optional] Elements to compare for the maximum. See [reduce](#) for details.

New in version 1.22.0.

Returns

nanmax

[ndarray] An array with the same shape as *a*, with the specified axis removed. If *a* is a 0-d array, or if axis is None, an ndarray scalar is returned. The same dtype as *a* is returned.

See also:

nanmin

The minimum value of an array along a given axis, ignoring any NaNs.

amax

The maximum value of an array along a given axis, propagating any NaNs.

fmax

Element-wise maximum of two arrays, ignoring any NaNs.

maximum

Element-wise maximum of two arrays, propagating any NaNs.

isnan

Shows which elements are Not a Number (NaN).

isfinite

Shows which elements are neither NaN nor infinity.

amin, fmin, minimum**Notes**

NumPy uses the IEEE Standard for Binary Floating-Point for Arithmetic (IEEE 754). This means that Not a Number is not equivalent to infinity. Positive infinity is treated as a very large number and negative infinity is treated as a very small (i.e. negative) number.

If the input has a integer type the function is equivalent to np.max.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, np.nan]])
>>> np.nanmax(a)
3.0
>>> np.nanmax(a, axis=0)
array([3., 2.])
>>> np.nanmax(a, axis=1)
array([2., 3.]
```

When positive infinity and negative infinity are present:

```
>>> np.nanmax([1, 2, np.nan, -np.inf])
2.0
>>> np.nanmax([1, 2, np.nan, np.inf])
inf
```

numpy.**minimum** (*x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]*) = <ufunc 'minimum'>

Element-wise minimum of array elements.

Compare two arrays and return a new array containing the element-wise minima. If one of the elements being compared is a NaN, then that element is returned. If both elements are NaNs then the first is returned. The latter

distinction is important for complex NaNs, which are defined as at least one of the real or imaginary parts being a NaN. The net effect is that NaNs are propagated.

Parameters

x1, x2

[array_like] The arrays holding the elements to be compared. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray or scalar] The minimum of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

See also:

maximum

Element-wise maximum of two arrays, propagates NaNs.

fmin

Element-wise minimum of two arrays, ignores NaNs.

amin

The minimum value of an array along a given axis, propagates NaNs.

nanmin

The minimum value of an array along a given axis, ignores NaNs.

fmax*, *amax*, *nanmax

Notes

The minimum is equivalent to `np.where(x1 <= x2, x1, x2)` when neither *x1* nor *x2* are NaNs, but it is faster and does proper broadcasting.

Examples

```
>>> import numpy as np
>>> np.minimum([2, 3, 4], [1, 5, 2])
array([1, 3, 2])
```

```
>>> np.minimum(np.eye(2), [0.5, 2]) # broadcasting
array([[ 0.5,  0. ],
       [ 0. ,  1. ]])
```

```
>>> np.minimum([np.nan, 0, np.nan], [0, np.nan, np.nan])
array([nan, nan, nan])
>>> np.minimum(-np.inf, 1)
-inf
```

`numpy.min(a, axis=None, out=None, keepdims=<no value>, initial=<no value>, where=<no value>)`

Return the minimum of an array or minimum along an axis.

Parameters

a

[array_like] Input data.

axis

[None or int or tuple of ints, optional] Axis or axes along which to operate. By default, flattened input is used.

If this is a tuple of ints, the minimum is selected over multiple axes, instead of a single axis or all the axes as before.

out

[ndarray, optional] Alternative output array in which to place the result. Must be of the same shape and buffer length as the expected output. See [ufuncs-output-type](#) for more details.

keepdims

[bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.

If the default value is passed, then *keepdims* will not be passed through to the `min` method of sub-classes of `ndarray`, however any non-default value will be. If the sub-class' method does not implement *keepdims* any exceptions will be raised.

initial

[scalar, optional] The maximum value of an output element. Must be present to allow computation on empty slice. See [reduce](#) for details.

where

[array_like of bool, optional] Elements to compare for the minimum. See [reduce](#) for details.

Returns

min

[ndarray or scalar] Minimum of *a*. If *axis* is None, the result is a scalar value. If *axis* is an int, the result is an array of dimension `a.ndim - 1`. If *axis* is a tuple, the result is an array of dimension `a.ndim - len(axis)`.

See also:

max

The maximum value of an array along a given axis, propagating any NaNs.

nanmin

The minimum value of an array along a given axis, ignoring any NaNs.

minimum

Element-wise minimum of two arrays, propagating any NaNs.

fmin

Element-wise minimum of two arrays, ignoring any NaNs.

argmin

Return the indices of the minimum values.

nanmax, maximum, fmax**Notes**

NaN values are propagated, that is if at least one item is NaN, the corresponding min value will be NaN as well. To ignore NaN values (MATLAB behavior), please use `nanmin`.

Don't use `min` for element-wise comparison of 2 arrays; when `a.shape[0]` is 2, `minimum(a[0], a[1])` is faster than `min(a, axis=0)`.

Examples

```
>>> import numpy as np
>>> a = np.arange(4).reshape((2,2))
>>> a
array([[0, 1],
       [2, 3]])
>>> np.min(a)           # Minimum of the flattened array
0
>>> np.min(a, axis=0)   # Minima along the first axis
array([0, 1])
>>> np.min(a, axis=1)   # Minima along the second axis
array([0, 2])
>>> np.min(a, where=[False, True], initial=10, axis=0)
array([10, 1])
```

```
>>> b = np.arange(5, dtype=np.float64)
>>> b[2] = np.nan
>>> np.min(b)
np.float64(nan)
>>> np.min(b, where=~np.isnan(b), initial=10)
0.0
>>> np.nanmin(b)
0.0
```

```
>>> np.min([[ -50], [10]], axis=-1, initial=0)
array([-50,  0])
```

Notice that the initial value is used as one of the elements for which the minimum is determined, unlike for the default argument Python's `max` function, which is only used for empty iterables.

Notice that this isn't the same as Python's `default` argument.

```
>>> np.min([6], initial=5)
5
>>> min([6], default=5)
6
```

`numpy.amin` (*a*, *axis=None*, *out=None*, *keepdims=<no value>*, *initial=<no value>*, *where=<no value>*)

Return the minimum of an array or minimum along an axis.

`amin` is an alias of `min`.

See also:

`min`

alias of this function

`ndarray.min`

equivalent method

`numpy.fmin` (*x1*, *x2*, */*, *out=None*, ***, *where=True*, *casting='same_kind'*, *order='K'*, *dtype=None*, *subok=True*, *signature*]) = `<ufunc 'fmin'>`

Element-wise minimum of array elements.

Compare two arrays and return a new array containing the element-wise minima. If one of the elements being compared is a NaN, then the non-nan element is returned. If both elements are NaNs then the first is returned. The latter distinction is important for complex NaNs, which are defined as at least one of the real or imaginary parts being a NaN. The net effect is that NaNs are ignored when possible.

Parameters

x1, x2

[array_like] The arrays holding the elements to be compared. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the *ufunc docs*.

Returns

y

[ndarray or scalar] The minimum of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

See also:

`fmax`

Element-wise maximum of two arrays, ignores NaNs.

minimum

Element-wise minimum of two arrays, propagates NaNs.

amin

The minimum value of an array along a given axis, propagates NaNs.

nanmin

The minimum value of an array along a given axis, ignores NaNs.

maximum, amax, nanmax**Notes**

The `fmin` is equivalent to `np.where(x1 <= x2, x1, x2)` when neither `x1` nor `x2` are NaNs, but it is faster and does proper broadcasting.

Examples

```
>>> import numpy as np
>>> np.fmin([2, 3, 4], [1, 5, 2])
array([1, 3, 2])
```

```
>>> np.fmin(np.eye(2), [0.5, 2])
array([[ 0.5,  0. ],
       [ 0. ,  1. ]])
```

```
>>> np.fmin([np.nan, 0, np.nan], [0, np.nan, np.nan])
array([ 0.,  0., nan])
```

`numpy.nanmin(a, axis=None, out=None, keepdims=<no value>, initial=<no value>, where=<no value>)`

Return minimum of an array or minimum along an axis, ignoring any NaNs. When all-NaN slices are encountered a `RuntimeWarning` is raised and `Nan` is returned for that slice.

Parameters***a***

[array_like] Array containing numbers whose minimum is desired. If *a* is not an array, a conversion is attempted.

axis

[{int, tuple of int, None}, optional] Axis or axes along which the minimum is computed. The default is to compute the minimum of the flattened array.

out

[ndarray, optional] Alternate output array in which to place the result. The default is `None`; if provided, it must have the same shape as the expected output, but the type will be cast if necessary. See `ufuncs-output-type` for more details.

keepdims

[bool, optional] If this is set to `True`, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *a*.

If the value is anything but the default, then *keepdims* will be passed through to the *min* method of sub-classes of *ndarray*. If the sub-classes methods does not implement *keepdims* any exceptions will be raised.

initial

[scalar, optional] The maximum value of an output element. Must be present to allow computation on empty slice. See [reduce](#) for details.

New in version 1.22.0.

where

[array_like of bool, optional] Elements to compare for the minimum. See [reduce](#) for details.

New in version 1.22.0.

Returns**nanmin**

[ndarray] An array with the same shape as *a*, with the specified axis removed. If *a* is a 0-d array, or if axis is None, an ndarray scalar is returned. The same dtype as *a* is returned.

See also:**[nanmax](#)**

The maximum value of an array along a given axis, ignoring any NaNs.

[amin](#)

The minimum value of an array along a given axis, propagating any NaNs.

[fmin](#)

Element-wise minimum of two arrays, ignoring any NaNs.

[minimum](#)

Element-wise minimum of two arrays, propagating any NaNs.

[isnan](#)

Shows which elements are Not a Number (NaN).

[isfinite](#)

Shows which elements are neither NaN nor infinity.

[amax](#), [fmax](#), [maximum](#)**Notes**

NumPy uses the IEEE Standard for Binary Floating-Point for Arithmetic (IEEE 754). This means that Not a Number is not equivalent to infinity. Positive infinity is treated as a very large number and negative infinity is treated as a very small (i.e. negative) number.

If the input has a integer type the function is equivalent to `np.min`.

Examples

```
>>> import numpy as np
>>> a = np.array([[1, 2], [3, np.nan]])
>>> np.nanmin(a)
1.0
>>> np.nanmin(a, axis=0)
array([1.,  2.])
>>> np.nanmin(a, axis=1)
array([1.,  3.])
```

When positive infinity and negative infinity are present:

```
>>> np.nanmin([1, 2, np.nan, np.inf])
1.0
>>> np.nanmin([1, 2, np.nan, -np.inf])
-inf
```

Miscellaneous

<code>convolve(a, v[, mode])</code>	Returns the discrete, linear convolution of two one-dimensional sequences.
<code>clip(a[, a_min, a_max, out, min, max])</code>	Clip (limit) the values in an array.
<code>sqrt(x, /[, out, where, casting, order, ...])</code>	Return the non-negative square-root of an array, element-wise.
<code>cbqrt(x, /[, out, where, casting, order, ...])</code>	Return the cube-root of an array, element-wise.
<code>square(x, /[, out, where, casting, order, ...])</code>	Return the element-wise square of the input.
<code>absolute(x, /[, out, where, casting, order, ...])</code>	Calculate the absolute value element-wise.
<code>fabs(x, /[, out, where, casting, order, ...])</code>	Compute the absolute values element-wise.
<code>sign(x, /[, out, where, casting, order, ...])</code>	Returns an element-wise indication of the sign of a number.
<code>heaviside(x1, x2, /[, out, where, casting, ...])</code>	Compute the Heaviside step function.
<code>nan_to_num(x[, copy, nan, posinf, neginf])</code>	Replace NaN with zero and infinity with large finite numbers (default behaviour) or with the numbers defined by the user using the <code>nan</code> , <code>posinf</code> and/or <code>neginf</code> keywords.
<code>real_if_close(a[, tol])</code>	If input is complex with all imaginary parts close to zero, return real parts.
<code>interp(x, xp, fp[, left, right, period])</code>	One-dimensional linear interpolation for monotonically increasing sample points.

`numpy.convolve(a, v, mode='full')`

Returns the discrete, linear convolution of two one-dimensional sequences.

The convolution operator is often seen in signal processing, where it models the effect of a linear time-invariant system on a signal [1]. In probability theory, the sum of two independent random variables is distributed according to the convolution of their individual distributions.

If `v` is longer than `a`, the arrays are swapped before computation.

Parameters

a

[(N,) array_like] First one-dimensional input array.

v

[(M,) array_like] Second one-dimensional input array.

mode

[{'full', 'valid', 'same'}, optional]

'full':

By default, mode is 'full'. This returns the convolution at each point of overlap, with an output shape of $(N+M-1,)$. At the end-points of the convolution, the signals do not overlap completely, and boundary effects may be seen.

'same':

Mode 'same' returns output of length $\max(M, N)$. Boundary effects are still visible.

‘valid’:

Mode ‘valid’ returns output of length $\max(M, N) - \min(M, N) + 1$. The convolution product is only given for points where the signals overlap completely. Values outside the signal boundary have no effect.

Returns**out**

[ndarray] Discrete, linear convolution of a and v .

See also:**`scipy.signal.fftconvolve`**

Convolve two arrays using the Fast Fourier Transform.

`scipy.linalg.toeplitz`

Used to construct the convolution operator.

`polymul`

Polynomial multiplication. Same output as `convolve`, but also accepts `poly1d` objects as input.

Notes

The discrete convolution operation is defined as

$$(a * v)_n = \sum_{m=-\infty}^{\infty} a_m v_{n-m}$$

It can be shown that a convolution $x(t) * y(t)$ in time/space is equivalent to the multiplication $X(f)Y(f)$ in the Fourier domain, after appropriate padding (padding is necessary to prevent circular convolution). Since multiplication is more efficient (faster) than convolution, the function `scipy.signal.fftconvolve` exploits the FFT to calculate the convolution of large data-sets.

References

[1]

Examples

Note how the convolution operator flips the second array before “sliding” the two across one another:

```
>>> import numpy as np
>>> np.convolve([1, 2, 3], [0, 1, 0.5])
array([0. , 1. , 2.5, 4. , 1.5])
```

Only return the middle values of the convolution. Contains boundary effects, where zeros are taken into account:

```
>>> np.convolve([1, 2, 3], [0, 1, 0.5], 'same')
array([1. , 2.5, 4. ])
```

The two arrays are of the same length, so there is only one position where they completely overlap:

```
>>> np.convolve([1, 2, 3], [0, 1, 0.5], 'valid')
array([2.5])
```

```
numpy.clip(a, a_min=<no value>, a_max=<no value>, out=None, *, min=<no value>, max=<no value>,
          **kwargs)
```

Clip (limit) the values in an array.

Given an interval, values outside the interval are clipped to the interval edges. For example, if an interval of `[0, 1]` is specified, values smaller than 0 become 0, and values larger than 1 become 1.

Equivalent to but faster than `np.minimum(a_max, np.maximum(a, a_min))`.

No check is performed to ensure `a_min < a_max`.

Parameters

a

[array_like] Array containing elements to clip.

a_min, a_max

[array_like or None] Minimum and maximum value. If `None`, clipping is not performed on the corresponding edge. If both `a_min` and `a_max` are `None`, the elements of the returned array stay the same. Both are broadcasted against `a`.

out

[ndarray, optional] The results will be placed in this array. It may be the input array for in-place clipping. `out` must be of the right shape to hold the output. Its type is preserved.

min, max

[array_like or None] Array API compatible alternatives for `a_min` and `a_max` arguments. Either `a_min` and `a_max` or `min` and `max` can be passed at the same time. Default: `None`.

New in version 2.1.0.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

clipped_array

[ndarray] An array with the elements of `a`, but where values $< a_{\min}$ are replaced with `a_min`, and those $> a_{\max}$ with `a_max`.

See also:

ufuncs-output-type

Notes

When `a_min` is greater than `a_max`, `clip` returns an array in which all values are equal to `a_max`, as shown in the second example.

Examples

```
>>> import numpy as np
>>> a = np.arange(10)
>>> a
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> np.clip(a, 1, 8)
array([1, 1, 2, 3, 4, 5, 6, 7, 8, 8])
>>> np.clip(a, 8, 1)
array([1, 1, 1, 1, 1, 1, 1, 1, 1, 1])
>>> np.clip(a, 3, 6, out=a)
array([3, 3, 3, 3, 4, 5, 6, 6, 6, 6])
>>> a
array([3, 3, 3, 3, 4, 5, 6, 6, 6, 6])
>>> a = np.arange(10)
>>> a
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> np.clip(a, [3, 4, 1, 1, 1, 4, 4, 4, 4, 4], 8)
array([3, 4, 2, 3, 4, 5, 6, 7, 8, 8])
```

`numpy.sqrt(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])`
= <ufunc 'sqrt'>

Return the non-negative square-root of an array, element-wise.

Parameters

x

[array_like] The values whose square-roots are required.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] An array of the same shape as *x*, containing the positive square-root of each element in *x*. If any element in *x* is complex, a complex array is returned (and the square-roots of negative reals are calculated). If all of the elements in *x* are real, so is *y*, with negative elements returning `nan`. If *out* was provided, *y* is a reference to it. This is a scalar if *x* is a scalar.

See also:

[cmath.sqrt](#)

A version which returns complex numbers when given negative reals. Note that 0.0 and -0.0 are handled differently for complex inputs.

Notes

sqrt has—consistent with common convention—as its branch cut the real “interval” $[-inf, 0)$, and is continuous from above on it. A branch cut is a curve in the complex plane across which a given complex function fails to be continuous.

Examples

```
>>> import numpy as np
>>> np.sqrt([1, 4, 9])
array([ 1.,  2.,  3.]
```

```
>>> np.sqrt([4, -1, -3+4j])
array([ 2.+0.j,  0.+1.j,  1.+2.j])
```

```
>>> np.sqrt([4, -1, np.inf])
array([ 2., nan, inf])
```

`numpy.cbrt` (*x*, /, *out*=None, *, *where*=True, *casting*='same_kind', *order*='K', *dtype*=None, *subok*=True[, *signature*])
= <ufunc 'cbrt'>

Return the cube-root of an array, element-wise.

Parameters

x

[array_like] The values whose cube-roots are required.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out*=None, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] An array of the same shape as *x*, containing the cube root of each element in *x*. If *out* was provided, *y* is a reference to it. This is a scalar if *x* is a scalar.

Examples

```
>>> import numpy as np
>>> np.cbrt([1,8,27])
array([ 1.,  2.,  3.])
```

`numpy.square(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'square'>`

Return the element-wise square of the input.

Parameters

x

[array_like] Input data.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

out

[ndarray or scalar] Element-wise $x*x$, of the same shape and dtype as *x*. This is a scalar if *x* is a scalar.

See also:

[`numpy.linalg.matrix\_power`](#)
[`sqrt`](#)
[`power`](#)

Examples

```
>>> import numpy as np
>>> np.square([-1j, 1])
array([-1.-0.j,  1.+0.j])
```

`numpy.absolute(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'absolute'>`

Calculate the absolute value element-wise.

`np.abs` is a shorthand for this function.

Parameters

x

[array_like] Input array.

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**absolute**

[ndarray] An ndarray containing the absolute value of each element in *x*. For complex input, $a + ib$, the absolute value is $\sqrt{a^2 + b^2}$. This is a scalar if *x* is a scalar.

Examples

```
>>> import numpy as np
>>> x = np.array([-1.2, 1.2])
>>> np.absolute(x)
array([ 1.2,  1.2])
>>> np.absolute(1.2 + 1j)
1.5620499351813308
```

Plot the function over $[-10, 10]$:

```
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(start=-10, stop=10, num=101)
>>> plt.plot(x, np.absolute(x))
>>> plt.show()
```

Plot the function over the complex plane:

```
>>> xx = x + 1j * x[:, np.newaxis]
>>> plt.imshow(np.abs(xx), extent=[-10, 10, -10, 10], cmap='gray')
>>> plt.show()
```

The `abs` function can be used as a shorthand for `np.absolute` on ndarrays.

```
>>> x = np.array([-1.2, 1.2])
>>> abs(x)
array([1.2, 1.2])
```

```
numpy.fabs(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
      = <ufunc 'fabs'>
```

Compute the absolute values element-wise.

This function returns the absolute values (positive magnitude) of the data in *x*. Complex values are not handled, use [absolute](#) to find the absolute values of complex data.

Parameters

x
[array_like] The array of numbers for which the absolute values are required. If x is a scalar, the result y will also be a scalar.

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where
[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default `out=None`, locations within it where the condition is False will remain uninitialized.

****kwargs**
For other keyword-only arguments, see the [ufunc docs](#).

Returns

y
[ndarray or scalar] The absolute values of x , the returned values are always floats. This is a scalar if x is a scalar.

See also:

absolute

Absolute values including *complex* types.

Examples

```
>>> import numpy as np
>>> np.fabs(-1)
1.0
>>> np.fabs([-1.2, 1.2])
array([ 1.2,  1.2])
```

```
numpy.sign(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature])
= <ufunc 'sign'>
```

Returns an element-wise indication of the sign of a number.

The *sign* function returns -1 if $x < 0$, 0 if $x == 0$, 1 if $x > 0$. `nan` is returned for `nan` inputs.

For complex inputs, the *sign* function returns $x / \text{abs}(x)$, the generalization of the above (and 0 if $x == 0$).

Changed in version 2.0.0: Definition of complex sign changed to follow the Array API standard.

Parameters

x
[array_like] Input values.

out
[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns

y

[ndarray] The sign of *x*. This is a scalar if *x* is a scalar.

[signbit](#)
[copysign](#)

Notes

There is more than one definition of sign in common use for complex numbers. The definition used here, $x/|x|$, is the more common and useful one, but is different from the one used in numpy prior to version 2.0, $x/\sqrt{x * x}$, which is equivalent to $\text{sign}(x.\text{real}) + 0j$ if $x.\text{real} \neq 0$ else $\text{sign}(x.\text{imag}) + 0j$.

Examples

```
>>> import numpy as np
>>> np.sign([-5., 4.5])
array([-1.,  1.])
>>> np.sign(0)
0
>>> np.sign([3-4j, 8j])
array([0.6-0.8j, 0. +1.j  ])
```

`numpy.heaviside(x1, x2, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature]) = <ufunc 'heaviside'>`

Compute the Heaviside step function.

The Heaviside step function [1] is defined as:

```
heaviside(x1, x2) = 0 if x1 < 0
                  x2 if x1 == 0
                  1 if x1 > 0
```

where *x2* is often taken to be 0.5, but 0 and 1 are also sometimes used.

Parameters

x1

[array_like] Input values.

x2

[array_like] The value of the function when *x1* is 0. If *x1.shape* $\neq$ *x2.shape*, they must be broadcastable to a common shape (which becomes the shape of the output).

out

[ndarray, None, or tuple of ndarray and None, optional] A location into which the result is stored. If provided, it must have a shape that the inputs broadcast to. If not provided or None, a freshly-allocated array is returned. A tuple (possible only as a keyword argument) must have length equal to the number of outputs.

where

[array_like, optional] This condition is broadcast over the input. At locations where the condition is True, the *out* array will be set to the ufunc result. Elsewhere, the *out* array will retain its original value. Note that if an uninitialized *out* array is created via the default *out=None*, locations within it where the condition is False will remain uninitialized.

****kwargs**

For other keyword-only arguments, see the [ufunc docs](#).

Returns**out**

[ndarray or scalar] The output array, element-wise Heaviside step function of *x1*. This is a scalar if both *x1* and *x2* are scalars.

References

[1]

Examples

```
>>> import numpy as np
>>> np.heaviside([-1.5, 0, 2.0], 0.5)
array([ 0. ,  0.5,  1. ])
>>> np.heaviside([-1.5, 0, 2.0], 1)
array([ 0.,  1.,  1.]
```

`numpy.nan_to_num(x, copy=True, nan=0.0, posinf=None, neginf=None)`

Replace NaN with zero and infinity with large finite numbers (default behaviour) or with the numbers defined by the user using the *nan*, *posinf* and/or *neginf* keywords.

If *x* is inexact, NaN is replaced by zero or by the user defined value in *nan* keyword, infinity is replaced by the largest finite floating point values representable by *x.dtype* or by the user defined value in *posinf* keyword and -infinity is replaced by the most negative finite floating point values representable by *x.dtype* or by the user defined value in *neginf* keyword.

For complex dtypes, the above is applied to each of the real and imaginary components of *x* separately.

If *x* is not inexact, then no replacements are made.

Parameters**x**

[scalar or array_like] Input data.

copy

[bool, optional] Whether to create a copy of *x* (True) or to replace values in-place (False). The in-place operation only occurs if casting to an array does not require a copy. Default is True.

nan

[int, float, or bool or array_like of int, float, or bool, optional] Values to be used to fill NaN values. If no values are passed then NaN values will be replaced with 0.0.

posinf

[int, float, or bool or array_like of int, float, or bool, optional] Values to be used to fill positive infinity values. If no values are passed then positive infinity values will be replaced with a very large number.

neginf

[int, float, or bool or array_like of int, float, or bool, optional] Values to be used to fill negative infinity values. If no values are passed then negative infinity values will be replaced with a very small (or negative) number.

Returns**out**

[ndarray] *x*, with the non-finite values replaced. If *copy* is False, this may be *x* itself.

See also:*isinf*

Shows which elements are positive or negative infinity.

isneginf

Shows which elements are negative infinity.

isposinf

Shows which elements are positive infinity.

isnan

Shows which elements are Not a Number (NaN).

isfinite

Shows which elements are finite (not NaN, not infinity)

Notes

NumPy uses the IEEE Standard for Binary Floating-Point for Arithmetic (IEEE 754). This means that Not a Number is not equivalent to infinity.

Examples

```
>>> import numpy as np
>>> np.nan_to_num(np.inf)
1.7976931348623157e+308
>>> np.nan_to_num(-np.inf)
-1.7976931348623157e+308
>>> np.nan_to_num(np.nan)
0.0
>>> x = np.array([np.inf, -np.inf, np.nan, -128, 128])
>>> np.nan_to_num(x)
array([ 1.79769313e+308, -1.79769313e+308,  0.00000000e+000, # may vary
        -1.28000000e+002,  1.28000000e+002])
>>> np.nan_to_num(x, nan=-9999, posinf=33333333, neginf=33333333)
array([ 3.3333333e+07,  3.3333333e+07, -9.9990000e+03,
        -1.2800000e+02,  1.2800000e+02])
>>> nan = np.array([11, 12, -9999, 13, 14])
>>> posinf = np.array([33333333, 11, 12, 13, 14])
>>> neginf = np.array([11, 33333333, 12, 13, 14])
>>> np.nan_to_num(x, nan=nan, posinf=posinf, neginf=neginf)
```
